In three cases, besides the subconjunctival injections, an intravaginal injection was made directly into the sheath of the optic nerve. For this purpose the tendon of the external rectus muscle was divided, sutures were introduced through the tendon so as to allow of its reattachment to the eyeball, and the muscle was then drawn upward and outward away from the wound. The conjunctiva was then carefully separated from the sclera as far as the apex of the orbit by strabismus hooks, and the optic nerve was drawn forward by a blunt hook. The sheath of the nerve was then grasped by a pair of fine forceps and lifted up, and the needle was pushed through the sheath parallel to the nerve, and the injection was made. The tendon of the muscle was then stitched to its former line of attachment to the sclera, the conjunctival wound was closed by a suture, and both eyes were bandaged for two days.

The vision existing in the two eyes of the several cases at the time the treatment was begun varied from light perception in both eyes as the lowest to 15/200 in both eyes as the highest. The injections were made at intervals varying from one week to every second day, and in the cases in which both eyes were seriously affected the injection was made in one eye, and at the next visit in the fellow eye. If there was no improvement after the tenth injection the treatment was abandoned. The drug used in every case was a solution of sublimate, beginning with 1 to 5,000 and increasing the strength of the solution to 1 to 2,000. The first injection consisted of 10 minims, and the dose was gradually increased until 20 minims were injected, and this dose was never exceeded. Each injection of the sublimate was preceded by an injection of 5 minims of a 5 per cent. solution of cocain, and in this way the pain was reduced to a minimum, and never lasted more than 5 or 6 minutes, and was characterized by the patient as a burning sensation. After the injection the eye was not bandaged, but cold applications were made to the eye until the burning sensation subsided. In no case was the injection followed by any marked signs of irritation, and the swelling of the subconjunctival space rapidly subsided under the influence of the cold applications.

The temporary improvement in the vision in three of the cases lasted but a short time. In one case, a man, aged 46, the left eye was entirely blind, while the right eye V.=5/200. After the sixth subconjunctival injection and one intravaginal injection the vision rose to 15/70 and remained so for five weeks. It then slowly grew worse, and in three months from the date of the last injection it was reduced again to 5/200. In the second case of improvement, V.=15/200 in each eye. After the sixth subconjunctival injection and one intravaginal injection in the right eye the vision of the right eye rose to 15/50—the left eye remaining unchanged; but the improvement lasted only four weeks and then

---

1. Deutschmann's Beiträge, vol. xv, p. 41.
2. Arch. f. Aug., 1904, p. 232.

rapidly sunk to 15/200. In the third case of improved vision the right eye was entirely blind and the left eye could count fingers at three feet. After ten subconjunctival injections and one intravaginal injection in the left eye the vision of the left eye rose within a few hours from counting fingers to 15/70 and the field was perceptibly widened. This patient lived in Texas and returned home two weeks after the last injection. He reported that the improvement of vision lasted four months and then rapidly subsided, so that three weeks later it was reduced to perception of light.

CONCLUSIONS.

1. Posterior subconjunctival injections of sublimate may be given with but little pain if the sublimate injection is preceded by the injection of cocain.
2. The conjunctiva should be incised and carefully separated from the episcleral tissue, and the injection made far back toward the apex of the orbit.
3. The eye need not be bandaged after the injection, but cold applications should be made for half an hour.
4. This method of treatment of cases of atrophy of the optic nerve has, in my hands, proved of no more value than the usual routine treatment by mercury, potassium iodid and strychnia, and offers no encouragement for its continued use.

DISCUSSION.

Dr. S. D. Risley, Philadelphia, said that the result of Dr. Bull's persistent experiments are negative and congratulated Dr. Bull on having the courage to announce such a result. He said that this is commendable and that he wished other experimenters had the courage to do the same in the case of similar results. Viewed from the standpoint of physiology and from what we know of the physiologic methods by which subconjunctival salt injections act, the result, Dr. Risley said, was an *a priori* conclusion. He is an advocate of subconjunctival salt injections; he has seen them do a great deal of good in diseases of the anterior segment of the globe and has many times seen the entire uveal tract clear up under the action of repeated, prudently made, subconjunctival salt injections. He said that by that he did not mean solution of mercury, but the so-called physiologic saline solution. He has never, however, seen any good effect from the deep injection of this or any other solution. He called attention to a point made by Dr. Bull, that in making these deeper injections we must go outside the capsule of Tenon and not into it. When we consider the peculiar anatomic arrangement of the optic nerve, how Nature by means of the dural sheath of the nerve, the curious complex arrangement between it and the pial sheath, the intricate arrangement of the blood vessels and the peculiar arrangement of the lymph spaces of the eye, we see how little is to be expected from deep injections. Dr. Risley does not know how salt injections do good. He does not believe, for example, that the law of osmosis and endosmosis has very much to do with it. He first supposed that that was the way in which it did good. He stated in a paper presented before this Section last year that it was simply the dilatation of the lymph spaces, with a fluid of proper specific gravity, thus permitting a freer current, as it were, and emptying the corneal lymph spaces, which were again filled by normal processes. He believes that all the good we can ever hope to accomplish from these salt injections must be by this method through the anterior lymph spaces of the eye, and that deeper injections are simply useless or harmful. He used them at first very extensively in his endeavor to cure that hopeless condition, detachment of the retina, but without results. How many of us, he asked, have not witnessed, day by day, this chamber of darkness gradually close around these patients with optic nerve disease while we sat sad and helpless, and who of us will not commend any procedure that brings a ray of hope? It is like casting one's fly into a quiet, currentless and fishless pool, where, however skillfully done, there must be disappointment, but we must conclude to accept many clinical disappointments in our efforts.

Dr. A. A. Hubbell, Buffalo, stated that he had had some experience along this line, though not so systematically persisted in as by Dr. Bull. These lamentable cases, he said, deserve all the attention we can give and if there is the slightest hope held out by anyone we are all disposed to grasp it. Some years ago he began the use of the subconjunctival injections and among others he experimented with this disease. His experience, like that of Dr. Bull's, has been entirely negative. Dr. Hubbell rather expected such results from the fact that he believes that we must look further than the eye itself for the cause of the disease. He has not felt that it is necessary to adopt the surgical measures that Dr. Bull has done in giving the injections. Dr. Hubbell has endeavored to place the sublimate solution beneath the capsule of Tenon by grasping the episcleral tissues with the forceps and then passing the needle underneath the tissues held up. In that way he has succeeded in putting the solution well back. He thinks that these negative results are as valuable to the profession as results which are more favorable.

Dr. George de Schweinitz, Philadelphia, said that our judgment of the value of any therapeutic measure is always greatly enhanced when we have a carefully diagnosticated series of cases to deal with. He has had no experience in the treatment of these cases with this method and asked Dr. Bull whether he believes this method persisted in in the manner and according to the technic he has described is more efficient than the ordinary method of giving subconjunctival injections in other conditions. Dr. de Schweinitz has given many hundreds of subconjunctival injections with all suitable substances, and with most satisfactory results in various diseases of the uveal tract, the cornea and the sclera, but he is willing to follow Dr. Bull's technic if it is more efficient.

Dr. Charles S. Bull, New York, in reply to Dr. de Schweinitz, said that if any effects are to result from this method of treatment on the condition of the optic nerve, the injections must be made, not anteriorly, but posteriorly. He had made a great many injections as he supposed posteriorly by simply grasping the conjunctiva and thrusting the needle through as far back as he could. Whether he is less skillful than others he does not know, but in every one of those cases he caused a great deal of pain to begin with, and the tendency of those injections was for the fluid injected to drift toward the anterior segment of the eye, in the circumcorneal spaces. When he first thought of opening the conjunctiva with scissors and separating it carefully as far back sometimes as the entrance of the optic nerve he found that the injection showed no tendency to come toward the anterior segment, but remained posteriorly where he wanted it. He has not found that these injections posteriorly had any more efficiency in producing favorable results on these conditions than those made in the anterior portion of the conjunctiva.

NEOPLASMS OF THE COLON.

REPORT OF SIXTEEN CASES.*

A. F. JONAS, M.D.
OMAHA.

Neoplasms of the colon, when compared with abdominal growths in general, are not common, still they are of sufficient frequency that they can not be left out of consideration when the surgeon is confronted by tumors of moderate size in any region of the abdominal cavity. When we take into consideration the wide range of mobility possessed by the colon, we at once must recognize the fact that position or location can be no determining factor in the diagnosis. These growths may be fixed in a given locality, which may or may not be at the point of their origin and the normal locality of the organ bearing them. They may be very movable and occupy a position at a considerable distance from their initial stage by displacing the organ that harbors them. While these neoplasms are usually palpable, they may be concealed and can not be felt even after they have attained a considerable size and have brought about a complete intestinal occlusion.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

While they usually begin as primary growths of the colon, they are not infrequently secondary and may have originated in the mesenterium or the appendix vermiformis of the uterus or its adnexa as will be seen from two cases detailed in this report. The primary growths may have developed so insiduously and pursued such a symptomless course as to be entirely unsuspected until by a hyperplastic inflammatory process they cause adhesions to the colon, having formed a vascular pseudomembrane between it and the neoplasm, the colonic wall rapidly becomes involved, gradually creating a narrowing of its lumen, with the frequent occurrence of sudden torsions and angulations, and occasionally when carcinomatous ulcerations extend into the outer intestinal tunic, the production of perforation ushering in a fatal peritonitis.

We must confess that physical signs alone are not sufficient to warrant a diagnosis. The history is of first importance and particularly a knowledge regarding certain functions.

PATHOLOGY.

Neoplasms of the colon present several varieties and in a general way we may designate, from a pathologic standpoint, two groups, viz., benign and malignant. In the first group we naturally place such connective tissue tumors as intestinal fibroma, lipoma, myxoma, and polypoids which appear as small nodular growths or as pendulous polyps. The latter occasionally produce intestinal obstruction and sometimes invagination. Myoma and multiple cysts have been met with.

Sarcoma of the intestine is extremely rare. Occasionally the solitary follicles of Peyer's patches may be at the seat of lymphadenoma or lymphosarcomatous enlargement, especially associated with leukemia or pseudoleukemia.

As an independent primary affection, round-celled sarcoma may spring from the submucosa and the deeper layers of the mucosa, sometimes extending to the mesentery. The mucosa and submucosa sometimes contains secondary sarcomatous nodules in considerable numbers and the peritoneal covering may be thickly infiltrated with miliary sarcoma points.

The malignant tumors of the intestine are chiefly of epithelial origin and under this caption must be counted not only carcinoma in all its varieties, but adenoma and inflammatory papilloma.

Chronic inflammations of the large intestine that result in inflammatory hyperplasia of the mucous membrane, sometimes terminate in papillomatous and polypoid formation of considerable extent.

While we can draw no sharp line between adenoma proper and inflammatory proliferations, the former, more strictly speaking, are tumors.

Adenomata may occur in the form of papillomatous cauliflower-like formations; or they may be found in the form of flat elevations of uneven surface and are prone to ulceration and hemorrhage.

Adenomata sometimes arise in the crypts of Lieberkühn in the duodenum of Müller's glands by an hyperplasia and in their makeup present typical glandular acini, a basement membrane containing cylindrical epithelium lining the tubules.

Adenomata are found sometimes in the colon, but more frequently in the rectum and rarely in the duodenum. Carcinoma is the tumor found most frequently in the intestine. It is observed most often in the colon and at the ileocecal juncture, at the flexures of the colon and least frequently in its descending portion. It is found sometimes in the duodenum, especially at the papilla of the common duct. More frequent than in all other parts of the intestine carcinoma is met with in the rectum.

Sutton collected 100 cases of carcinoma of the intestine. Of these 75 were located in the rectum, 23 in the colon and only 2 in the small intestine.

The collective reports of tables of autopsies published by Azeman, Maydl, Müller and Nothnagel, show an aggregate of 69,083 autopsies, of these 5,796 deaths were from carcinoma in general, about 84 per cent. Of the 5,796 deaths from carcinoma, 1.296 were in the intestinal canal, making 22.35 per cent. of all carcinomata. Thirty-five of these occurred in the duodenum and small intestine (2.7 per cent); 35 were in the cecum (2.7 per cent.); 131 in different parts of the colon (10.11 per cent.); three in the vermiform appendix (23 per cent.); 83 in the sigmoid (6.405 per cent.); 262 in the rectum (20.25 per cent.) (Hemmeter). It will thus be seen that 19.422 per cent. of all intestinal cancer occur in the large intestine if we include the sigmoid, nearly 80 per cent. of these occurring in the rectum.

Carcinoma of the colon presents an irregularly formed mass, containing hard and soft areas, often ulcerated especially within the intestinal lumen, which bleeds easily and projects into the gut, reducing its diameter and interfering with the fecal passage, or when the growth is girdle-shaped and surrounds the gut, which is its most characteristic form, its lumen is narrowed, interfering with fecal circulation. As the intestinal constriction becomes greater the colon above the point of stricture becomes greatly distended by the accumulating gases and fecal masses. The bowel below the obstruction becomes thinner and its lumen contracted. The distension may become so great as to produce rupture.

Carcinomata of the colon are, chiefly, cylindrical epitheliomata of glandular cancers, being made up of atypical acini and tubules, epithelial cells in masses which have irregularly proliferated and infiltrated the neighboring tissues. Occasionally these neoplasms have been found a clear transition of adenoma into carcinoma (adenocarcinoma). Thus transformation is not uncommon in tumors of the bowel.

Cancer of the large intestine is usually of primary origin, but rarely is it secondary, and when so it has spread to the intestine by contiguity from the omentum, stomach, uterus, ovary, bladder, prostate glands, vermiform appendix and lymphatic glands, or cellular elements may be transferred from other distant organs wherein a primary carcinoma may be undergoing disintegration.

Carcinoma of the intestine and particularly of the colon, occurs chiefly between the ages of 40 and 60 years, although these growths are sometimes observed earlier. Nothnagel records a case of carcinoma of the cecum in a boy 12 years of age; Schönig two cases of rectal carcinoma in girls of 17 years of age; and Clar reported a case of medullary carcinoma in a boy three years old (Hemmeter). Maydl has shown by material of the

Allgemeines Krankenhaus, in Vienna, that one-sixth of all intestinal cancers occur between the ages of 30 and 40 years and one-seventh occur before the thirtieth year, consequently it is not safe to exclude cases from a diagnosis of intestinal cancer on account of age.

Adhesions between the neoplasm and all organs may give rise to great misplacement of viscera creating great operative difficulties. Sometimes many loops of intestine have become adherent to each other as well as to the neoplasm and all of these to the bladder, uterus, ovaries, and omentum, creating an entanglement that is impossible to disentagle. Adhesions may create fistulæ between colon and intestine or bladder, occasionally perforations externally through the skin have been observed. A primary neoplasm may become so large as to occlude the intestine; in many instances such a growth may disintegrate, a portion of it slough away and the obstruction is relieved, to be followed by a constriction due to connective tissue formed in the place of the disintegrated portions. During a partial disintegration of such a growth, blood vessels become eroded and severe loss of blood may ensue. If the disintegration process extends to and through the peritoneum before agglutinative adhesions with adjacent parts have taken place, a fatal peritonitis follows.

SYMPTOMATOLOGY.

There is no disease of the intestine that in its early stages is usually so free from symptoms. It develops so slowly that its presence is unsuspected until more or less grave complications are manifest. Every practitioner can detail cases that have progressed to a point where a fatal termination was imminent from sudden bowel obstruction and yet no tumor was palpable because of its concealment under the left costal arch as in one of our cases. Others have been recorded and observed many times, where gradual emaciation, a cachexia and a gradually increasing constipation was the only warning. Again others with an unimpaired appetite and digestion, no loss in weight and the only manifestation the obstinate and aggravated bowel inactivity that gave cause for alarm.

The common early subjective indications are frequently recurring colic-like pains with circumscribed tenderness, unpleasant abdominal fullness due to accumulation of gas, with bowel inactivity alternated sometimes with diarrhea. These symptoms were present in nearly all of our cases. Particularly, the cramp-like pains that increased in severity and frequency until either a tumor could be palpated or bowel obstruction was complete. These colicky pains were more or less associated with abdominal fullness, tension and a point of tenderness.

The digestive functions were unimpaired, as one would expect in growths situated so low down in the intestinal tract, as the colon plays no important part in digestion or assimilation. These symptoms are not pathognomonic of malignancy nor do they indicate the presence of a tumor in any form. They seem to indicate that a more or less localized lesion exists which may be inflammatory or neoplastic. There is no justification for an absolute diagnosis of neoplasms of the colon, whether with or without the above symptoms, unless we can feel a tumor that seems to have no connection with other organs. The evidence becomes strong when gurgling of gas through the tumor is heard. The diagnosis becomes more certain when an obstinate and increasing constipation exists and it is usually quite certain when in the presence of a hard irregularly-shaped tender tumor, a bowel obstruction exists. The author has found in several of his cases a strong confirming evidence to the use of the stethoscope, frequently on auscultation a gurgling of air through that portion of the intestine in which the growth was located, could be heard. Another valuable aid consisted in air being pumped into the rectum through a long tube. The little jets of air could be heard through the stethoscope up to the point of partial or complete obstruction but not beyond.

In several of the cases when the bowel had become partially obstructed, the fecal column was flattened, compressed, stringly and spirally molded, sometimes the stool was dry and globular. But these signs can not be considered of much importance because a constricted sphincter ani might, in a measure, cause unusual forms of the feces. The stool, however, is often very offensive, owing to the disintegration of the neoplasm. The evacuations then may contain pus, mucous and blood in varying quantity, the hemorrhage being sometimes dangerously profuse. Care should, however, be exercised to ascertain if hemorrhoids in any form are existent. Occasionally particles of the growth are found in the evacuations, but usually escape detection. It is well, however, to examine the stools critically for such broken-off particles.

It is remarkable how long some of these cases can exist even after obstruction is complete. One of our cases was seen three weeks after the last evacuation. The colon is susceptible of great enlargement, sometimes being so large that on first inspection after opening the abdomen, one is uncertain whether or not he is dealing with the stomach. The enormously dilated colon can accommodate an immense quantity of firm stool, the fluids having been reabsorbed.

DIAGNOSIS.

It is very important that frequently repeated palpation of the abdomen in suspected intestinal neoplasms be done in various positions, sometimes under an anesthetic. Rectal and vaginal explorations are important because the neoplasm may of its own weight have sunk into the pelvis or have been drawn out of place by adhesions. It must be remembered that neoplasms of the colon, in their early development, are apt to be round or oval, smooth and not very large, not large enough to cause the abdominal wall to project. Later they become uneven and irregular in shape and sensitive. If located in the transverse colon a distinct aortic impulse is present. Growths of the ascending transverse and descending colon, if palpable at all, are usually freely movable and are located below the umbilical line. Owing to the varying amount of intestinal gas from day to day the tumor may be felt at one examination and elude detection in subsequent examinations, hence the necessity of frequent investigations. Percussion is not of much value. Fecal impactions not uncommon, may be so confusing as to make a diagnosis difficult and sometimes impossible.

The peristaltic wave is important; in some of our cases it was so distinct that the distended intestinal coils could be plainly seen and in two instances we obtained most excellent photographs. So frequently was this condition observed, that when present, it was regarded an important sign of probable bowel obstruction and taken together with several of the aforesaid symptoms was regarded as a reliable diagnostic factor.

Case 1.—*Primary. Endocarcinoma. Located in Sigmoid. Removed. Ends closed-lateral anastomosis. Needle and Thread. Recurrence in five months.*

History.—Mrs. S. P., aged 42, had four children. Menses were always regular until last six months when they became more profuse but not excessive. No leucorrhea. She always enjoyed good health, bowels always regular until six months ago, when an occasional cathartic became necessary. Constipation increased so that repeated daily efforts with cathartics and enemata would after three to four days produce an evacuation and finally all efforts were unavailing.

Examination.—On admission uterus was only moderately movable, very tender and to it seemed to adhere a soft doughy mass whose outlines were difficult to fix in an upward direction. Its lower border seemed fairly well circumscribed. It seemed to fill the iliac fossa. There was much very severe abdominal pain. No discernible peristaltic wave but much gurgling of gas.

Operation.—The upper end of the sigmoid was found adherent to the uterus and that portion of the gut above the point of adhesion filled with a large mass of feces and gas. This proved to be the tumor that was palpable before the operation. The gut was separated but the adhesion surface was suspicious of malignancy. The gut above and below the point of constriction was clamped and the mass removed. The distal and proximal gut ends differed so greatly in diameter, owing to the distended central end, that an end-to-end anastomosis was deemed inadvisable, consequently both ends were closed by purse string suture, and a lateral approximation done with needle and thread. The growth proved to be an adenocarcinoma.

Case 2.—*Secondary. Papillomatous ovarian. Descending colon. Removed end-to-end. Czerny-Halstead Suture. Double suspension suture from recurrence. Free after one year. Lost from sight.*

History.—Mrs. M. M. A., age 44, has always been constipated since girlhood. Has taken all forms of cathartic and in large doses. Has had three children, menstruates regularly with little pain. Since four months she has had severe griping pains of more or less intensity sometimes requiring anodynes. She complained of frequent and annoying rumbling in her bowels, especially during attacks of pain. She has lost no flesh, appetite and digestion normal. It became more difficult to procure bowel evacuation until finally all efforts failed.

Examination.—On admission I find her in good condition. Abdomen moderately tympanitic, slightly tender over every portion except in left iliac fossa where pain is severe on pressure. Bimannal examination discloses an enlarged slightly tender uterus, in left parametrium a movable, tender, orange-sized mass. It is believed that there may be a bowel adhesion to this mass. Operation advised and accepted.

Operation.—Median incision. Mass in left side proved to be an ovarian papilloma to which is adherent the lower end of the descending colon, in fact, the colon seemed to be incorporated into the papillomatous mass. The growth is ligated at its base and separated from its uterine attachment. The gut is doubly clamped above and below the neoplasm and removed. The bowel is joined by an end-to-end anastomosis by a continuous Czerny suture and two rows of Halstead sutures. Nature of growth, secondary papilloma.

Case 3.—*Primary. Adenocarcinoma. Located in upper end descending colon. 1. Short circuit, Murphy button. 2. Growth removed, ileo-colostomy. End to side. Recurrence in twelve months. Death in eighteen months.*

History.—Mr. L. S., age 60, mechanic, American, complains of much abdominal pain of a cramp-like character often vomits and has obstinate constipation. He states that his illness began four weeks ago with severe griping pain and more or less constant desire to move the bowels but he was usually unsuccessful. Purgatives sometimes produced evacuations but always associated with severe pain. These symptoms have become progressively worse until the date of our first examination.

Examination.—Temperature normal. Pulse, 120. Respiration, 40. General abdominal tenderness most severe near the left costal margin, but no tumor could be made out, chiefly on account of the tenderness. An operation was advised chiefly on account of the apparent bowel obstruction.

Operation.—Through a median incision extending above the navel a mass could be felt in the upper portion of the descending colon. It was hard and firm, moderately movable. The condition of the patient was so unfavorable that an immediate removal of the growth was deemed advisable; consequently a lateral anastomosis was established between the transverse and the descending colon with a large Murphy button. The button holding perfectly, the abdominal wound was closed. The patient recovered quickly from the anesthesia and in an hour passed a large amount of flatus, and on the second day with the aid of a small enema a large bowel movement occurred. The button passed on the twelfth day. The general strength returned rapidly so that on the twentieth day after the first operation a second one was done for the purpose of removing the neoplasm. Through a high incision in the left semilunar line the growth was exposed. It was first detached from its mesenterial attachments. Two long hemostatic clamps above and below the tumor were applied and the gut between the two clamps resected. The intestinal ends were inverted and closed. The anastomosis opening from the first operation seemed perfect. The abdomen was closed without drainage. Nature of growth adenocarcinoma.

Case 4. — *Primary. Adenocarcinoma (ileocolostomy). Located in ileocecum. 1. Artificial anus from ileum. 2. Lateral approx. Needle and thread. Well six months later, not heard from since.*

History.—Mrs. T. R., aged 50, had good health until 18 months ago, when she experienced colicky abdominal pains, particularly in the right hypochondrium, sometimes associated with vomiting. Bowels fairly regular. No blood in the stools. Her weight gradually diminished. The abdominal pains became more frequent and more severe.

Examination.—Present state. Abdomen moderately distended. Manipulation caused visible peristaltic waves, especially in the right iliac fossa. In this region could be felt a fist-sized elastic tumor. Gas could be heard to pass through it, probably through the ileocecal valve. Bowel passages were obtained only by artificial aid.

The diagnosis was bowel obstruction in all probability due to a malignant neoplasm. The loss of flesh and cachexia associated with a palpable neoplasm seemed to warrant this conclusion. The pain and vomiting increased, the obstructive symptoms and the great prostration seemed to indicate an immediate interference. An operation was accordingly advised and promptly accepted.

Operation.—Chloroform. A section in the median line revealed a mass of distended intestines. Exploration was unsatisfactory. The neoplasm in the right iliac fossa could be felt but not accurately outlined. The patient appeared extremely exhausted, haste seemed imperative, consequently a loop of ileum was drawn out of the wound and carefully surrounded by gauze swabs, an incision into the ileum was made, permitting the escape of a large amount of flatus and fecal matter. The intestinal opening was closed and the loop of ileum was fastened to the abdominal wall for the purpose of making an artificial anus according to Maydl. The loop of ileum opened 36 hours later and a large amount of flatus and fecal matter was evacuated. The abdomen became flat in twenty-four hours. The general condition of the patient improved very rapidly and she gained in weight and strength rapidly. In two weeks the patient was up and about her home. Three weeks from the date of her operation a second operation was made to restore the continuity of the intestinal canal.

Second Operation.—Incision through the linea semilunaris revealed an orange-sized growth involving the ileocecal junction almost closing the ileocecal valve. The loop of ileum, which was attached to the abdominal wall, proved to be afferent iliac limb of the loop making the artificial anus. This loop together with the cecal tumor was removed, and the afferent limb of the artificial anus was closed. The closed end of the ileum was placed against the closed colon and a lateral anastomosis made with needle and thread. Further exploration of the abdominal cavity revealed no other pathology, consequently the abdomen was sutured. The opening that had been occupied by the artificial anus was then closed. Recovery was uneventful. Nature of growth of adenocarcinoma.

Case 5.—*Primary. Adenocarcinoma. Located in ascending colon. Hepatic flexure. Excision, ends closed, lateral approx. Murphy button. Well two years later.*

History.—Mr. H. A., laborer, aged 38. There was vomiting of especial moment in the early history. The present illness began nearly two years ago with occasional griping pains in the abdomen. These were believed to be due to gastric disturbances. After an unusual exertion some six months ago, followed by an unusual amount of pain in the abdomen, he observed for the first time a lump in the right side. He had for a considerable period been very much constipated. There had been a gradual loss in weight and he became gradually pale and weak.

Examination.—Status Præsens. Patient of medium height, well built, very pale. The abdomen symmetrical, shows a distinct fullness in the right flank. A distinct irregularly rounded mass can be palpated in the right hypochondriac and right lumbar regions, which can be moved upward and downward and laterally almost to the median line. The lower border is three fingers breadth below the transverse navel line. It appears to have no connections with the liver. The mass can be pushed almost into the renal fossa. It is only slightly tender. No tender points in any other part of the abdomen. Leucocyte count, 20,000, Hemoglobin, 45 per cent., red corpuscles, 4,000,000. urine clear, sp. gr. 1.020, alb., 0, sugar, 0. No renal elements microscopically. Temperature and pulse normal. The mobility, size and location of the tumor suggested a renal origin. The absence of all microscopic elements in the urine indicated an extra renal origin. A constantly increasing and stubborn constipation seemed to indicate an intestinal origin. The opinion is strengthened by the statement of the patient that he can feel a bubbling of gas toward and away from the tumor. He states that he can distinctly feel gas moving toward the mass where it seems to be arrested for a few seconds and then it passes beyond and away from it. The passage of gas can sometimes be felt with the palpating hand. The stenoscopic examination plainly indicated the passing of gas through the growth. Percussion gave a flat tympany.

Examination of stomach contents one hour after an Ewald's test breakfast, gave the following. Acid reaction, odor sour, distinct red color with phloro-glucin-vanillin solution. Inflation indicated normal position and size of the stomach; the growth was in no way affected. Tapping the abdominal walls with the finger tips started peristaltic waves which could be plainly seen passing across the upper part of the abdomen from left to right, at the same time bubbles of gas could be felt with the hand and heard through the stethoscope, passing through the tumor.

From the above findings it was believed that tumor of renal origin could be excluded. The test-meal investigation was negative as to stomach or pyloric involvement. There appeared to be no origin in the liver on account of tumor movements independent of the liver. Clearly we had to do with an intestinal neoplasm; its mobility, the passage of gas through it, the arrest of the peristaltic wave by it, together with the obstinate and increasing constipation indicated its presence. Its location suggested the hepatic flexure and transverse colon as its seat. An operation was advised and eagerly agreed to by the patient.

Operation.—Incision through right linea semilunaris reveals a mass involving one-half of the ascending and hepatic colonic flexure, which can be lifted into the wound. Mass is excised between clamps, two above and two below the growth. The ends of the colon are closed and a lateral approximation with a Murphy button is made. The abdomen is closed without drainage. Recovery uneventful. Nature of growth adenocarcinoma.

Case 6.—*Secondary. Cicatricial mass. Located in descending colon from uterus and tube. Removed end-to-end suture. Double supporting loop. Lost sight of after two months.*

History.—Mrs. J. A. S., aged 42, American, has had three children, last one five years old. One year ago began having colicky pains at intervals. Bowels had always been regular. began to be irregular requiring an occasional cathartic until three months ago, constipation began to get progressively worse, requiring cathartics in increasing doses and frequency until within the week preceding admission large doses of cathartics and enemata were only slightly successful. She had observed a profuse menstrual flow and occasional uterine hemorrhage in excretion.

Present State.—Apparently in good health, quite fleshy. Has lost no noticeable weight. Examination discloses an enlarged and tender uterus in normal position. Palpation produces slight uterine hemorrhage. In the left parametrium can be felt a moderately movable hen's-egg-sized swelling which was believed to originate in the left ovary or tube and probably had become adherent to the rectum causing the constipation.

Operation.—Abdominal section disclosed an enlarged uterus irregular, slightly nodular fundus. The descending colon was prolapsed and its lower end firmly adherent to the posterior and left side of the uterus, together with an old pyosalpinx. The sigmoid was crowded down into the cul-de-sac forming several reverse coils. The adherent coil was separated with the scissors and packed with gauze swabs and pushed aside. The uterus and adnexa were removed in toto. Then the adherent portion of the bowel, which was a cicatricial mass was excised and an end-to-end enterostomy was done using the double loop supporting ligature. Nature of constriction cicatricial.

Case 7.—*Primary. Adenocarcinoma. Located in ileocecal region. Ileum planted into the side of colon. Murphy button. Lost sight of four months later.*

History.—Mrs. H. S., age 51, housewife. Her present illness began six months ago with constipation, which had increased so that her bowels moved only every three to five days and then only after repeated artificial aid, usually evacuating hard and lumpy feces. These periods of obstinate constipation have several times yielded to looseness, the stools being yellow and slimy, but containing no blood, nor did she complain of teneseness. Several weeks ago, she vomited a sour material, but no blood. She has lost much in weight. Exertion causes shortness of breath; recently her feet became swollen. Constipation was present but could be relieved.

Examination.—Although the patient appears somewhat pale, she is well nourished; normal temperature, slightly coated tongue. Abdomen somewhat distended. In the ileocecal region is a distinct elevation that is not affected by the respiratory movements nor by position. On palpation can be felt a goose-egg sized rounded nodular mass about midway between the anterior superior spinous process and the umbilicus. It can be felt immediately beneath the abdominal wall, not tender, very hard. It is freely movable and can easily be crowded under the navel. With a stethescope occasional bubbles of gas can be heard to pass toward it, which are arrested for an instant and then pass on. A flat tympany can be elicited on light percussion. No peristaltic waves. The tumor could be pushed upward almost to the liver but not to it nor into the renal fossa, neither could it be made to descend into the pelvis. Test meal was negative as to stomach disease. Urinary analysis revealed no pathologic conditions.

The clinical evidence indicated an intestinal growth, probably ileocecal, but that was not certain.

Operation.—An incision through the linea semilunaris revealed a tumor involving the entire head and circumference of the cecum and the lower wall of the ileum. The mass was easily removed together with about three inches of the ascending colon and about two inches of the ileum. The open end of the colon was closed with a Czerny-Lembert suture. The end of the ileum was implanted into the inner side of and about one and one-half inches above the closed end of the ascending colon, by means of a Murphy button. Patient died on fourth day from perforation at site of anastomosis. The growth proved to be an adenocarcinoma.

Case 8.—*Primary. Neoplasm located in lower end of descending colon. Relieved by short circuit with Murphy button. Died in three months.*

History.—Mr. W., age 58, about six months before admission. was struck on the left lower quadrant of the abdomen. He continued his work during the day but after retiring he had nausea and vomiting, and abdominal pain. The left iliac pain has continued since the accident. often worse at night ference is deferred until the clinical signs are positive, i. e., when bowel obstruction is complete and a tumor can be felt, then metastatic deposits have become so extensive that we can scarcely hope to eradicate all the pathologic structures. It is true we still can very often remove the principal growth, restore the continuity of the bowel lumen and achieve an operative recovery, but in the light of the present status of bowel surgery, we must expect an all too great recurrence percentage. Surgeons have dreaded to enter the abdomen when the clinical signs were doubtful. So did they, not so very long age, where the bile tracts of the appendix were involved, chiefly because they had not become familiar with definite and well defined diagnostic signs and on the other hand on account of the uncertain technic in dealing with these organs. The same holds true of neoplastic intestinal obstruction. Sometimes the signs are absolute and yet it is with dread that most surgeons attack these cases. An intestinal neoplasm usually involves a resection.

The principles involved in such a procedure are well defined, but the details of such an operation are countless. No two operators accomplishing the same result employ the same methods. I am sure that this unsettled operative condition is responsible for much procrastination. It will be seen from the cases here detailed that a variety of methods of bowel union were used. Without going into a discussion of the respective merits of the various methods, it may be briefly stated that from the experience gained from our cases of neoplasms of the large intestine as well as bowel obstruction due to inflammatory and mechanical causes, two principal procedures for the restoration to the continuity of the bowel have commended themselves as easy and rapid of accomplishment, viz.: First, in cases where the resected ends were not entirely free from inflammatory conditions, a closure of both ends of the bowel with purse string and Lembert sutures, after the removal of the neoplasm, and a lateral approximation near the ends and the establishment of an anastomosis with suture aided by the Moynihan clamps; and, second, after the removal of the neoplasm and the bowel was otherwise sound, an end-to-end union with a Connell and Cushing suture aided by the double loop suspension ligature were found most practical and easy of application. The merits of these methods will be the subject of another communication at another time and place.

THE SURGICAL CONCEPTION OF SIGMOID PATHOLOGY.*

H. D. NILES, M.D.
SALT LAKE CITY, UTAH.

In the evolution of intraperitoneal surgery, our progress has invariably been from a resultant or terminal pathology to the antecedent or original pathology; from the well-advanced and easily discovered lesions to the earlier and more obscure departures from normal. Gradually, step by step, as our knowledge has widened by experience and study, we have learned that large pelvic abscesses have small beginnings in an infected tube or endometrium; that cancer of the gall bladder or stone in the ducts means a previous infection of the parts; that malignant disease of the rectum, stomach or uterus is usually preceded by benign localized inflammatory or necrotic lesions, and we have learned to take into thoughtful account the physiologic and anatomic peculiarities of these different regions in connection with their etiologic bearing on pathologic conditions, and, lastly, as better results followed timely surgery, we have won the confidence and co-operation of our colleagues, the internists, without which many victims of intraperitoneal pathology must still have suffered or died, with their malady unrecognized, untreated or mistreated. So it has been in other parts of the abdomen, and so we have reason to hope it will be in sigmoid disease.

MORTALITY.

So long as our surgical endeavors are limited to advanced malignant disease and acute obstruction from volvulus, we can not reasonably hope to reduce the present high mortality that attends sigmoid operations. So soon as we learn to recognize, trace and interpret the successive morbid processes, that unchecked lead up to dangerous terminal pathology, we may confidently expect to realize the full benefits of timely and preventive surgery here as in other parts of the body.

In spite of the absence or scarcity of statistical operating-room and postmortem evidence, there are good reasons for believing that the sigmoid must often be the site of important pathologic processes deserving surgical consideration, of which only the small proportion that terminate in cancer or complete obstruction of the bowels are usually recognized.

ANATOMIC CONDITIONS.

No one familiar with the surgical anatomy of the sigmoid can fail to be impressed with the existence of conditions that must render this part of the alimentary canal especially susceptible to disease and accident. It is a constricted irregularly tortuous portion of the large intestine, firmly attached at either extremity by a comparatively short mesentery, the middle portion freely movable, being connected by a long mesosigmoid, and would seem to present every opportunity for the occurrence of twists and angulations (Fig. 3).

A sagging descending colon, with its loose attachment, favors angulation at the upper extremity of the sigmoid, while angulation of the lower extremity can easily occur when the middle portion falls over the more closely attached distal end of the sigmoid. Under the head of volvulus, only those distortions are described as are seen more or less imperfectly in operations, but experimentally various other twists and angulations may be produced in a way to obstruct the bowels partially or completely.[1]

It is highly probable that partial obstructions of the large intestine, malignant and benign, occur at this point much oftener than is generally believed; for unless the obstructive symptoms are urgent these cases rarely come under the observation of the surgeon and in most instances escape recognition. In the light furnished by experiments on the cadaver and recent clinical observations, I feel sure that I have in the past treated the vast majority of these cases symptomatically with no conception of the real causes of the symptoms, and doubtless others have often made the same error.

In no part of the gastrointestinal canal are the anatomic conditions so favorable for the development of ulcer. Hardened fecal matter passing from a large straight canal through a smaller tortuous one, frequent temporary angulations, with the occasional sagging of one part over another, are markedly irritating factors, all favoring localized inflammatory and necrotic lesions. Long-continued pressure of fecal accumulations on the intestinal wall, by interference with the circulation, may induce local necrosis; any twists or compression of the mesosigmoid may produce the same result by interrupting the blood supply, and these last-mentioned causative factors of ulcer must often be operative in this region.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[1] Volvulus is permitted by a long mesocolon, but the direct cause must be either trauma, or more frequently mechanical obstruction at the distal end, sufficient to distend and displace the middle portion of the sigmoid.

PATHOLOGY AND LOCATION OF LESIONS

Ulcer and angulation are doubtless often associated, with the former as the usual primary causative factor. In two of my operations I found the bowel angulated at the juncture of the descending colon with the proximal extremity of the sigmoid, and an ulcer at the angle, which gave way when I attempted to restore the parts to their normal position (Fig. 1). It is easy to understand how most permanent angulations or twists of the sigmoid are preceded or followed by an open or cicatrized ulcer and how recurring angulations or twists might be more likely to occur about the contracting scar of an old ulcer.

On the other hand, it is true that pus collections can not often occur in sigmoid pathology, for, unlike the infected Fallopian tube, appendix and bile ducts, where drainage is imperfect or impossible, the anatomy of the sigmoid permits good drainage from the mucosa, which is the usual site of infection. A perforating ulcer, however, might result in abscess here, as it often does in the stomach ulcer.

It is a remarkable fact that not less than 87 per cent. of all cancers of the gastrointestinal tract are situated in the narrow strictured parts of the canal, the sigmoid standing third in point of frequency. It surely can not be chance or the operation of any general cause that so distinctly marks these parts as the favored sites of malignant disease. This overwhelming predominance of cancer in certain regions can only be due to a local cause; and, so far as can be determined, that local cause is chronic ulcer, or its cicatrix. It can not matter whether that ulcer is produced by hyperacidity of the gastric juice, stagnation of the bowel contents, abnormalities of the sphincters, or the irritation or pressure of hardened feces on the intestinal wall, so long as we know that ulcer is essential to the development of cancer and the prevalence of cancer indicates the relative frequency of ulcer.

But since recent studies in stomach pathology go to show that only a small proportion of gastric ulcers terminate in cancer, and that a large majority of these ulcers either cicatrize spontaneously or remain open indefinitely, it is apparent that ulcer is far more frequent than cancer, and, as this doubtless holds as true of the sigmoid as of the pylorus, we may assume that ulcer of the sigmoid is of very common occurrence.[2]

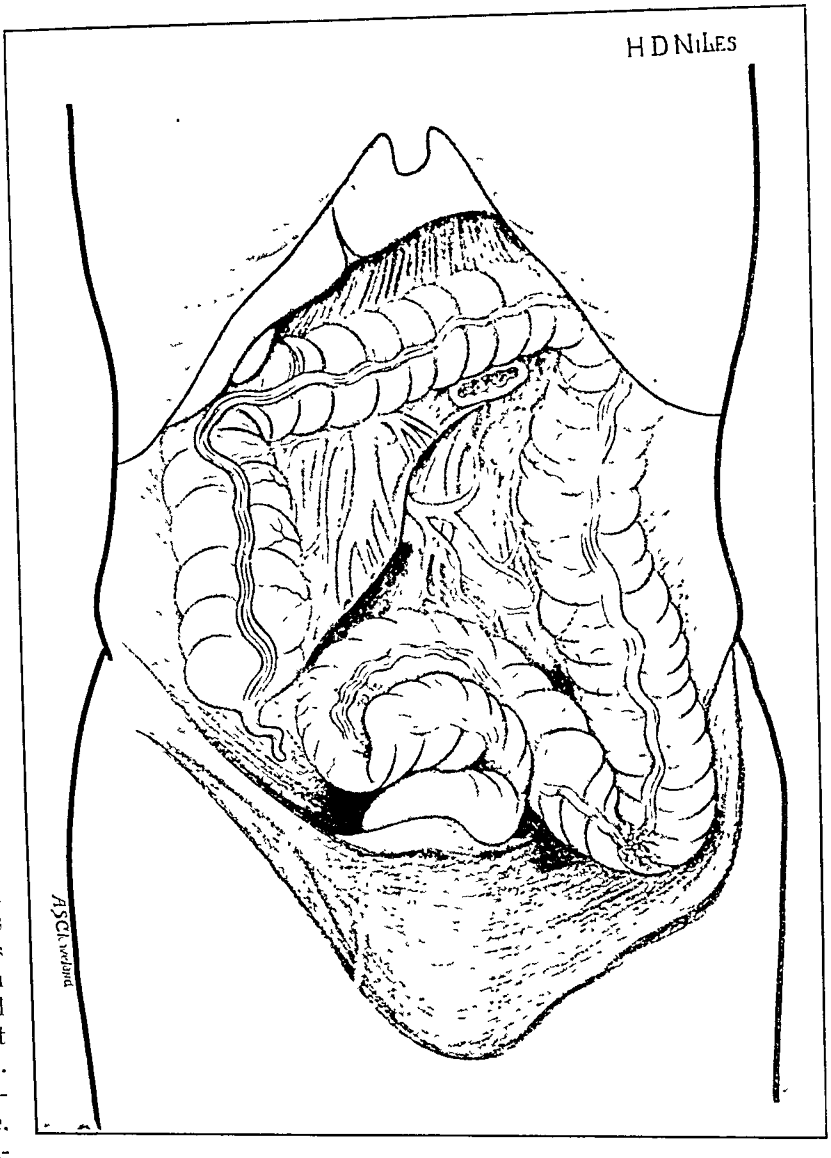

Fig. 1.—Showing commencing ulcer and angulation at proximal and distal ends of sigmoid.

Incomplete, non-malignant stricture, with or without a twist or angulation of the bowel, probably ranks next to ulcer in point of frequency and in time of occurrence. This belief is based on: First, the known tendency of intestinal ulcer to produce cicatricial stricture; second, the ease with which stenosis can be produced by twisting or angulating the sigmoid in the cadaver; third, the history of gradual occlusion elicited from a good proportion of the patients operated on for complete obstruction; fourth, the marked symptoms of stenosis of the sigmoid observed in a number of patients not operated on; fifth, the assumption that any contracting ulcer, perhaps insufficient to produce occlusion itself, might favor angulation with resulting obstructive symptoms. I have several patients under observation who present to my mind convincing evidence of chronic incomplete stricture or stenosis of the sigmoid. and at least three of my non-malignant cases, in which the patients were operated on for complete obstruction, gave a distinct history of gradual occlusion extending over a period of several months. The apparent slow development of sigmoid cancer noted by most careful observers should, I am sure, be interpreted as an evidence of a precancerous pathology rather than a deviation from the general law that the progress of malignant disease is essentially rapid.

---

[2] A good proportion of our office patients complaining of chronic obscure abdominal symptoms should be examined for sigmoid ulcer.

In the fewest possible words I have attempted to show, first, how ulcer must of necessity be the usual primary lesion resulting from the anatomic and physiologic peculiarities of the sigmoid; second, that cancer here, as in the stomach, is preceded by ulcer; third, that ulcer is always the causative factor in annular stricture; fourth, that it is the most influential factor in sigmoid angulation and one of the predisposing causes of accidental volvulus; fifth, that, as a consequence, it is the important antecedent pathology of all malignant and most non-malignant, complete and incomplete occlusions of the sigmoid.

It must be admitted that the present available statistical, operating-room and postmortem evidence is not alone sufficient to prove these statements, but in a careful study of my own cases and those of thirty well-known American surgeons with whom I have been in correspondence I had hoped to include an analysis of these clinical statistics, but space will not permit.

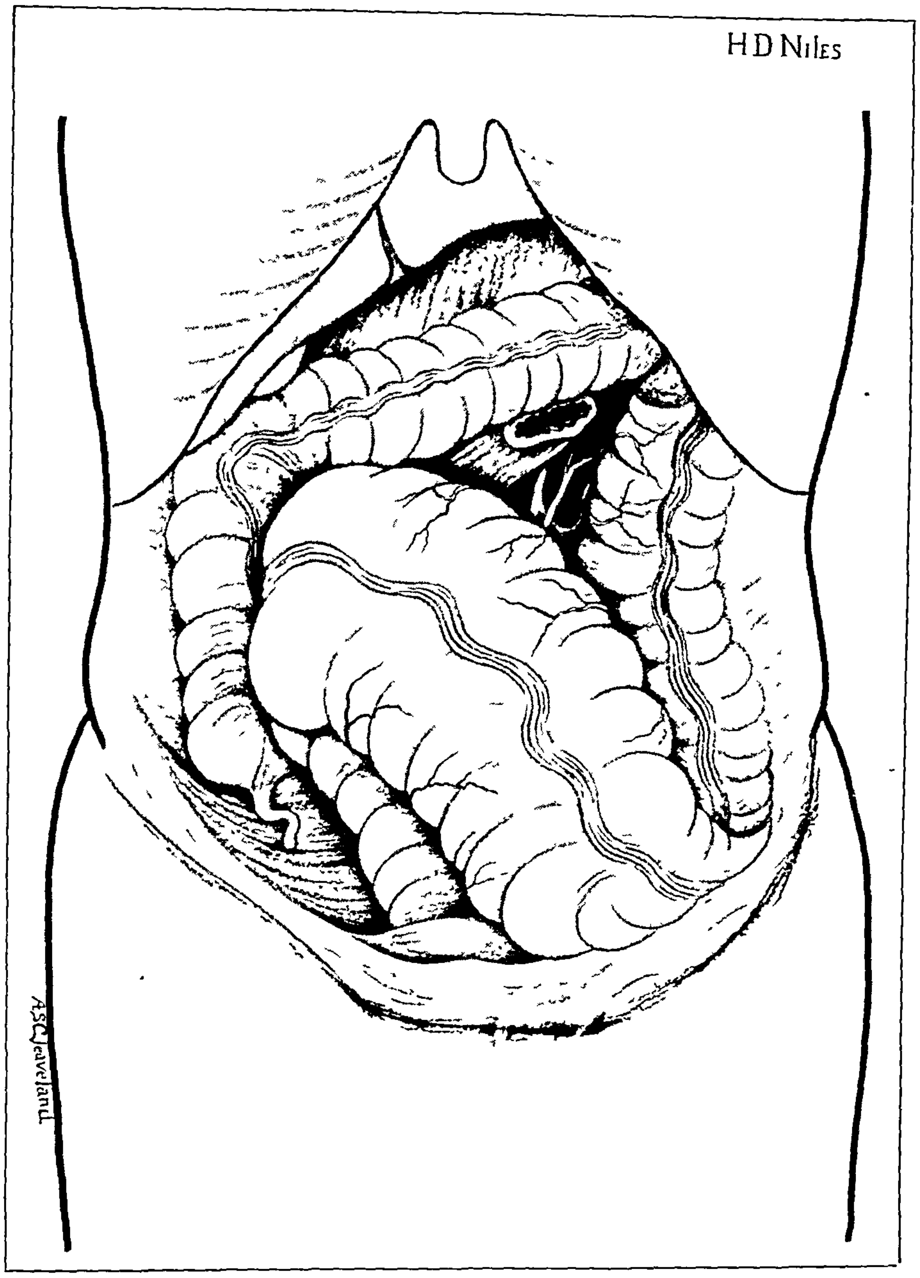

Fig. 2.—Stricture of proximal extremity of sigmoid, showing enormously distended sigmoid after inflation.

The chief (and I think sufficient) support of these conclusions comes from the following facts: First, our knowledge of the surgical anatomy of the sigmoid, gleaned from studies and experiments on the cadaver; second, the relations between ulcer and cancer and ulcer and pyloric stenosis as taught by recent observations made during operations on the stomach; third, the known relative frequency of sigmoid cancer and the occasional occurrence of acute obstruction of non-malignant origin; fourth, the fact that every variety of ulcer, even typhoid, has frequently been found in this region; fifth, the fact that ulcer is the only lesion that could be the common result of the anatomic peculiarities and at the same time the common cause of the terminal pathology of the sigmoid.

If my reasoning is sound and my conclusions are true, or even approximately true, the early recognition and rational treatment of sigmoid ulcer and its complications are worthy of the most careful consideration of both internists and surgeons. The limits of this paper will not permit me to dwell on the symptomatology of sigmoid ulcer, but those who realize the frequency of ulcer in this region and the distress and danger that may ultimately result from ulcer will not measure the gravity of the lesion by the mild symptoms that characterize its early stages. A suggestive history, the exclusion of other diseases, the absence of acute inflammatory symptoms, the left-sided tenderness, either with or without inflation of the bowel, the distension of the colon, the colicky pains, the presence of pus or blood in the stools, obstinate constipation or obstructive symptoms, are all indicative of sigmoid pathology.

METHOD OF EXAMINING THE SIGMOID.

There is one method of examining the sigmoid that I think deserves special mention. Inspection, palpation and percussion before, during and after inflation of the bowel with air or distension with water may be of the greatest value in determining whether or not the lumen is narrowed by stricture, angulation or distortion, and in this way we may even determine the degree and location of any stenosis. Pressure on the distended bowel will often enable us to locate the point of tenderness that otherwise might not be discovered. A fixed point of tenderness without stenosis would point to the probability of an ulcer which might cicatrize spontaneously. Narrowing of the lumen of the bowel with or without tenderness would indicate a permanent lesion or a progressive pathologic process that might in time become a menace to life or health (Figs. 2, 4 and 5).

BASIS FOR RATIONAL TREATMENT.

Any rational treatment of sigmoid disease must be based on our conception of the successive pathologic links that connect the anatomic and physiologic peculiarities of the sigmoid with the dangerous inflammatory and obstructive lesions which we find in late operations. To recognize and to interrupt this process at the earliest possible moment, and before irreparable damage has been done, becomes the aim of those who appreciate the relative frequency and importance of sigmoid pathology in each stage of its progress.

Pathology here passes from the medical to the surgical field: First, when any ulceration or necrotic process starting in the mucosa extends to or includes the peritoneum; second, whenever there is any evidence of mechanical obstruction, partial or complete, regardless of the cause; third, when a localized peritonitis exists that does not readily yield to simple measures directed to the suspected cause. This does not mean that every such case should be subjected to immediate operation, but that the decision as to when, when not and how to operate can best be made by those who view these conditions from a surgical standpoint. Medicines, especially cathartics, are always useless and frequently harmful.

The essential principle of treatment of sigmoid ulcer, like that of gastric ulcer, is rest. How best to secure that rest with the least distress and the greatest assurance of safety to the patient no one may as yet presume to state dogmatically. The starvation plan, irrigations from below, or continuous currents of aqueous solutions from above, through an opening in the colon; or in the presence of chronic stenosis or threatened occlusion, iliosigmoidostomy, excision of the ulcer, or exsection of the diseased portion of the gut, are all procedures that may be considered.

In formulating the treatment of a pathology that has rarely been seen or studied except in the most advanced stages we can not expect at once to be free from doubts and misgivings, but as we gradually learn to outline and to carry to the consulting room and bedside a well-defined mental picture of the successive morbid processes in sigmoid disease, more accurate methods of diagnosis will be suggested and more effective means of treatment will be evolved; and we may be assured that in this region, as in other parts of the body, symptomatic medication and "last resort" surgery will in due time be supplanted by rational measures and timely operative procedures.

DISCUSSION.

ON PAPERS OF DRS NILES AND JONAS.

Dr. William H Wathen, Louisville, Ky., said that recently, while preparing a paper on gastro enterostomy, he corresponded with five men whom he considered among the most distinguished surgeons in Europe in abdominal work—the late von Mikulicz, Kocher, Czerny, Robson and Moynihan—and five distinguished surgeons of this country. The inquiry was as to the kind of anastomosis they make and what method of suturing they use From the correspondence, he was fairly convinced of the fact that the tendency was to eliminate, as far as possible, all mechanical means in making any sort of anastomosis of the intestinal tract, from the stomach to the sigmoid flexure. He believes that the Murphy button has done more in the process of evolution to show what can be done in anastomosis of the intestinal tract than anything else, and by its use it has been possible to demonstrate conclusively the promptness of firm union in properly coapted surfaces; and, also, that in the hands of the experienced abdominal surgeon the use of the suture is the safest and best method in nearly all cases. Therefore, he advises the use, with few exceptions, of the continuous suture, and especially where it is possible to use Moynihan's method of bringing the parts of the intestinal tract in apposition by including each side in a forcep covered by gum tissue. The continuous uninterrupted suture should usually be used, because it is easily and quickly applied, insures more perfect apposition, and is followed by fewer immediate or ultimate complications. Simplicity and rapid technic must be emphasized as essential factors in intestinal surgery.

Dr. R. H. M. Dawbarn, New York, said that at one time he thought that the plates carved from sweet or white potatoes, and the buttons and bobbins he divised of the same material (raw vegetable tissue) were an improvement on the decalcified bone plates of Senn. Perhaps they were; but he has not used anything of the kind for many years. For over fifteen years he has used the continuous linen suture in gut-work, plus a single temporary stitch, so placed as to make smoothly tense the surface being sewn together. He is convinced that simple suturing is the safest method and the best, and that in place of the Connell method, with interrupted stitches, the continuous suture (running Lembert) is the safest, using linen thread. But the continuous suture is not a safe one unless one uses with it the morphin splint, administering morphin, so as to put a stop to peristalsis for the time being, until (in a few hours), union is certain to be firm. Otherwise, the continuous suture might cut out at some point, and the wound gape in consequence. Of course, the saving of time in using the continuous suture is the main thing. This point can not be made too strongly.

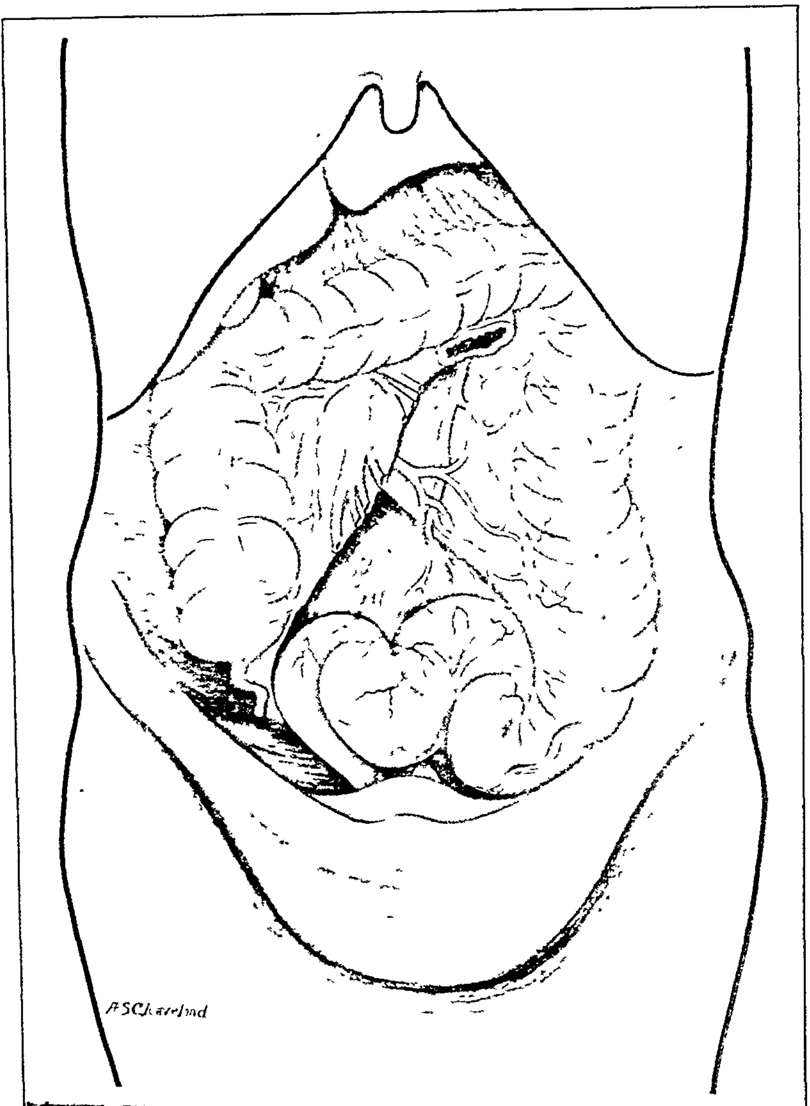

Fig. 3.—The normal sigmoid. From many observations made by the author in the course of his operative work.

As regards the Murphy button: If one uses it anywhere in the bowel without the row of sutures about it, then one is depending on Nature to throw out a plastic exudate to surround the region; and experienced surgeons have had the sad experience of killing one or more patients, before they learned not to trust to Nature in this matter. If one sews all the way round the Murphy button in order to make it safe, then its chief advantage, that of speed, is done away with. One can suture by a running continuous simple Lembert stitch as quickly as one can put in a Murphy button and suture all the way round. Another objection to the Murphy button is that when it cuts loose, one is not sure that it will cut loose on the right side—the proximal—of the anastomosis. He has had the unpleasant experience of having the button go the wrong way, by reverse peristalsis. That is called vomiting when it occurs in the stomach, but when it occurs in the intestine there has no name been given to it. It is a condition that is liable to go on for hours and even for days; and there may be just enough contraction of the anastomotic opening so that the button never passes that point. Dr. Wyeth once reported a case where for more than 120 days the button wandered around between the anastomosis on the one hand and the stomach on the other, until the patient could not stand the colic and misery any longer and a second laparotomy was done for the purpose of removing the button. The patient again got well. But any form of anastomosis that runs even the slightest chance of risk entailing another laparotomy is not to be recommended, in comparison with an anastomosis leaving no foreign body, requiring no especial instrument for its performance, and as quick as the speediest, namely: Continuous suturing of surface, made tense, to aid speed, and safeguarded against leakage, both by rapid, plastic exudate of Nature's glue (because of light scraping of peritoneal surfaces about to be sewn together), and also by the morphin splint, carrying out that cardinal principle of good surgery, to put operated parts absolutely at rest.

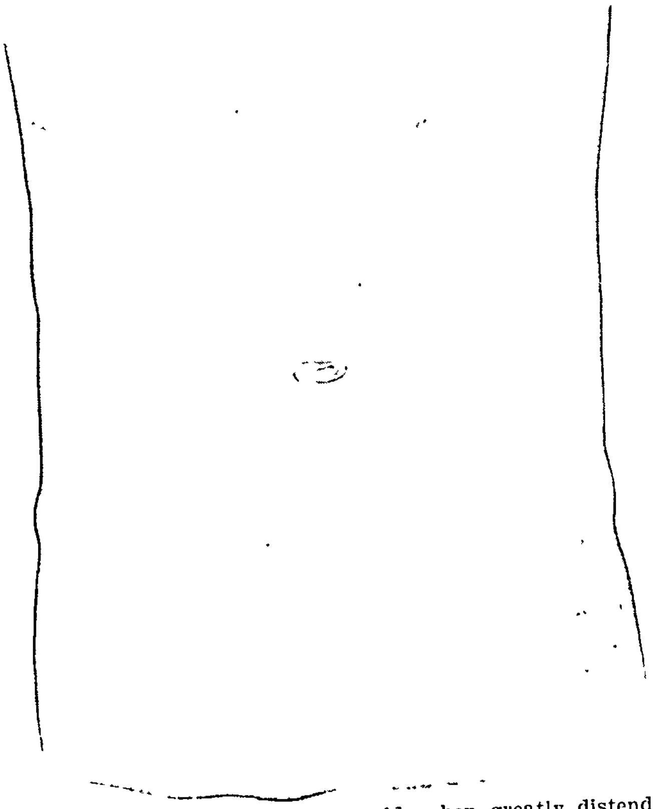

Fig. 4.—The outlines of the sigmoid, when greatly distended, as observed through the abdominal wall. This distension may occur when there is a tight stricture of the distal extremity of the sigmoid, or it may be produced by artificial inflation of the lower bowel, when the stricture is at the proximal end of the sigmoid.

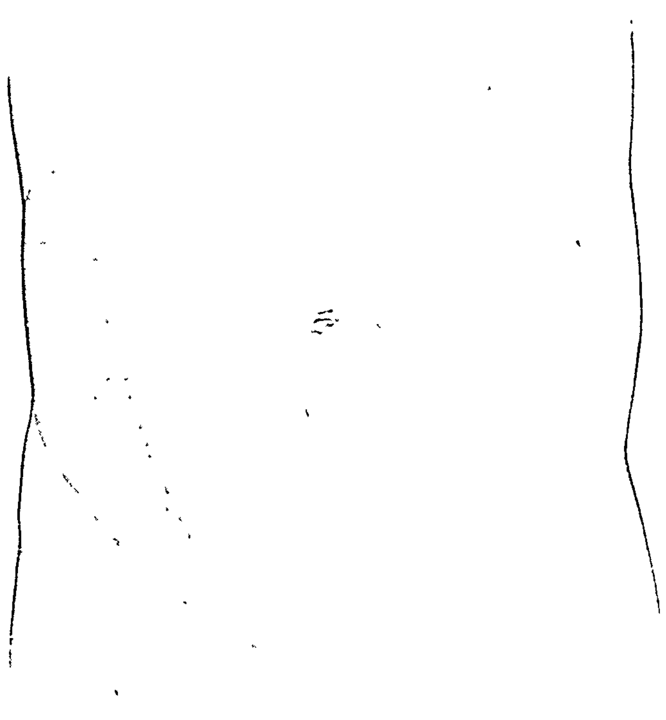

Fig. 5.—Another view of an enormously distended sigmoid. Figures 4 and 5 are redrawn from Nothnagel's "Diseases of the Intestines and Peritoneum."

Dr. F. A. Dunsmoor, Minneapolis, has been in the habit of using a button when making a gastrointestinal anastomosis, for one particular reason. The button leaves, after its escape, a peculiar circle which does not grow smaller as time goes on. This he has verified in postmortem examinations three years after operations. He has yet to hear anyone say that the opening between the stomach and the intestine did contract after having been made in the circular manner, when a Murphy button was used, no matter what became of the button afterward. He uses the suture in the colon since the button may temporarily obstruct the bowel. The lower in the intestinal tract the greater demand for the suture, but he prefers the button for operation high up in the small intestine.

As to the amount of colon to be resected. He began that work through emergency surgery, and removed the shortest possible damaged portion only. The physiologists say that the colon is not indispensable—that it does not digest food, but does absorb it, and thus helps nutrition. Dr. Dunsmoor resected the ascending colon from the head of the cecum for malignant disease, and the sigmoid and a large part of the descending colon for the same cause; but it remained for Mr. Arbuthnot Lane, of London, to give him courage to remove the colon from the terminal portion of the ileum to the splenic flexure for ulcerative colitis. Mr. Lane goes farther and removes the colon for obstinate chronic constipation.

Dr. E. W. Andrews, Chicago, called attention to the fact over fifteen years ago Dr. Nicholas Senn, at that time of Milwaukee, was making his classic experiments on the intestine of the dog, which preceded the Murphy button, and practically all intestinal work which is now so much perfected. His colleague in that research was Dr. Connell, of Milwaukee, to whom Dr. Senn gave the credit in his first book, of having devised the first bone plates for intestinal anastomosis. D Connell devised the through and through suture which hold the plates, and also one without plates. Later, Dr. F. Gregor Connell perfected what is now known as the Connell enterorhaphy, by employing it, ever since the Connells demonstrated their method in their dog experiments. Dr. Andrews has been a firm believer in the Connell suture as being the very strongest known in intestinal anastomosis. He employs it not only for anastomosis of the small and large bowel, but also for pylorectomy and gastroenterostomy. The suture has certain merits over all known stitches, the bone plates and buttons. It has at the same time the action of a clamp and of a suture line, going from the lumen of one hollow viscus to that of the next, including every layer, even the mucosa, traversing transversely through them all. When an anastomosis is made no thread can be seen from the peritoneal side, which is in distinct contrast to the Maunsell suture, where the knot lies across the suture line. Dr. Connell, when he first described this operation, gave the option between using the stitch continuously and using it interruptedly. Nine times out of ten Dr. Andrews used the suture continuously, making a back stitch about every fourth insertion of the needle. This prevents puckering and back-slipping. He was interested to note during a visit to the Mayo's clinic last fall that in performing pylorectomy, making the duodenal insertion, according to Kocher's method, they were using the Connell suture. He said that in Chicago and the West, the Connell suture has established itself most thoroughly.

Dr. F. Gregory Connell, Salida, Colo., said that the suture operation has resolved itself into the perforating and the non-perforating suture. The advantage of the perforating suture is its security. The disadvantage is a possible capillarity. This subject, the capillarity of intestinal sutures, he submitted to the section during this meeting and, therefore, did not discuss it further at this time. (The Journal, Aug. 11, 1906, page 405).

Dr. L. Freeman, Denver, called attention to the comparatively favorable prognosis of cancers of the sigmoid flexure, and cited a case which came to his notice about a year and a half ago. The patient had, in addition to the carcinoma of the sigmoid, involvement of the urinary bladder and of the peritoneal surface of the abdominal wall, so that it was necessary, in removing the tumor of the bowel, also to remove quite a large portion of the bladder and peritoneum and to resect, perhaps, six inches of the colon. Notwithstanding this complication the patient is perfectly well. Eighteen months have elapsed since the time of the operation.

Dr. A. McGlannan, Baltimore, emphasized the importance of intermittent intestinal obstruction as a symptom of cancer of the bowel. Since Dr. Bloodgood called his attention to this symptom, about two years ago, he has seen it seven times in cases where a tumor was not palpable. In all these cases there was a history of intermittent obstruction, and in each instance a cancer of the large intestine of some kind was found at the operation. That seems to be a point in diagnosis, to be borne in mind in these cases.

Dr. Charles Stoltz, South Bend, Ind., has found that it is exceedingly difficult to determine the exact nature of the obstruction previous to operation. He had a case of this kind nearly two years ago, that of a woman, 42 years of age, who had suffered since childhood from intermittent obstruction. Finally, about December, 1904, her symptoms became so intense that she sought surgical assistance. It seemed that the obstruction followed periods of fatigue. On New Year's day, after entertaining at her home, she became unable to continue her household duties. When Dr. Stoltz first saw her she had symptoms which led him to believe that she had obstructive adhesions or a small umbilical hernia, especially because of the manner in which the umbilicus was pulled about with the violent intestinal peristalsis. However, on opening the abdomen there was no evidence of adhesions or of a hernia. At the beginning of the sigmoid, however, there was a constriction and a thickening of the bowel for about five inches, the lumen being as small as a lead pencil. There were several lesser constrictions about this point, but otherwise nothing abnormal was found. He did an ileosigmoidostomy and the woman was well for about six months, when symptoms of obstruction reappeared. Recently she took a long, restful trip. During all that time she had absolutely no signs of any disturbance. Her husband, who is a physician, said that she had never been in better health. She returned home, became tired again, and her difficulty recurred. He has been unable to decide on the exact pathology. Of course, it may be ulcer or non-malignant tumor, but the fact that fatigue brought on these attacks of intermittent obstruction and that they were absent during periods of rest is an interesting feature in the case and suggestive of a neurosis.

Dr. J. B. Boucher, Hartford, Conn., said that a straight needle and a piece of linen thread are the best contrivances to be used for these cases, where there is time. In some cases, where the condition of the patient is such as to require rapid work, the Murphy button must be used. He has not had any experience with the opium or morphin splint, of which Dr. Dawbarn spoke, but it seemed to him that it might prove useful. Last year he reported six cases of resection of the bowel for cancer. Since then he has had two more, also five or six for non-malignant conditions, making thirteen or fourteen cases in all. In all these cases he used only the straight needle and the linen thread, and he has not had any mortality. Dr. Boucher thinks that in cases of cancer of the bowel the dissection should always be carried wide of the cancer. If a thorough resection is done, even desperate cases will recover from the operation and remain well for a number of years. He did a resection of the colon five years ago and the man is still living and well. The glands were enlarged clear into the pelvis and he could not get at all of them. It was a case of adenocarcinoma. Resection can be done as well, and nearly as rapidly, as anastomosis around the growth. It is strange that such patients seem to have immunity from infection to a certain extent, and their reparative power seems to be greater than that of the ordinary individual.

Dr. J. A. MacMillan, Detroit, said that although resection of a portion or of the entire colon for chronic inflammation or ulceration has been advocated by Arbuthnot Lane and others for some time, he does not believe such extreme measures for these conditions will obtain the favor of the profession. It is possible that in very aggravated cases, in which stricture seems inevitable, a resection is justifiable, but even in such cases the ulceration should be taken care of first by more conservative methods. He believes that the rational method of treating these cases is by temporary colostomy. The physiologic rest obtained in this way is followed by rapid disappearance of the ulceration and inflammation, and when the healing process is complete the artificial anus may be obliterated.

Dr. H. D. Niles said that it has become almost a habit with surgeons and internists to exclude all kinds of abdominal surgery, except in those cases that are attended by acute pain, tremor, febrile symptoms or acute obstruction. The treatment of ulceration is rest in some form. In regard to the favorable results obtained in operations on the colon, that has been the observation of all who have done much work on the large intestine, while the reverse is true in the case of the small intestine. It is surprising how many cases of malignant disease of the large intestine will survive an operation and live for years without a recurrence. He has used the Murphy button and some other appliances, and he would not like to say that he would never use them again, but gradually he has accustomed himself to do the suture operation and he likes it very much better. It has been quite a long time—years—since he used the Murphy button. He thinks that the linen thread undoubtedly is the best suture, but there is a linen, the celloidin linen, that is anhydrous. It does not soil or take up fluid or infection, and it seems to be the ideal suture material for intestinal work. He has used it and always with satisfaction. It is easier to do comparatively dextrous work with it than with any other material. The fact that it is anhydrous assures one that it is not likely to become infected, no matter what method of suturing is employed.

Dr. A. F. Jonas said that the purpose of his paper was three-fold. First, to call attention to the necessity of early recognition of this condition; second, to outline the pathology; third, to restore the continuity of the bowel after it had been broken by removal of the growth. The question of early diagnosis here is exactly the same as that of early recognition of cancer of the pylorus. The trouble with the latter is that usually surgeons wait until they can feel a lump, and then when they operate they find extensive invasion of adjacent organs. The operative success may be good, but the result obtained is not a permanent one on account of early recurrence. The same is true of neoplasms of the colon. By waiting until the tumor can be felt, and sometimes nothing else can be done, the metastases have become so extensive that recurrence takes place very soon after the operation. So that it is of the greatest importance to make use of every diagnostic aid in order to establish at least a probable, if not an absolute, diagnosis in these cases.

The methods of re-establishing the continuity of the bowel that have given Dr. Jonas the best satisfaction are the closing of the ends of the intestine by a purse-string suture and then making lateral anastomosis with suture, assisted by the Moynihan clamps, using an interrupted or continuous through-and-through suture. When the Connell suture is used there need be no fear of the tearing out of the sutures, providing the tissues are healthy. Dr. Jonas uses the Connell suture, assisted by the double loop mentioned in his paper. It is easy, rapid and safe, particularly if finally supported by a right-angle Cushing suture, and there is no danger of leakage.

TREATMENT OF ULCER OF THE STOMACH, WITH A RECORD OF CASES.*

HENRY F. HEWES, M.D.
Instructor in the Clinical Laboratory Harvard Medical School.
BOSTON.

In the treatment of ulcer of the stomach in its various forms we have to-day two general methods—medical treatment and surgical treatment.

In cases of simple, uncomplicated ulcer, that is, ulcer with or without hemorrhage, uncomplicated by permanent obstruction of the pylorus, or perforation, medical treatment offers an efficient, though not an absolutely certain, means of cure. This treatment gives in this class of cases almost universally good results as regards immediate relief or temporary and, if the treatment is thoroughly carried out, excellent results as regards permanent cure.

The efficiency of the treatment as regards the after-results or permanent cure is dependent to a large extent on its thoroughness. In cases in which treatment is completely carried out, that is, when strict treatment is enforced for a considerable period, a period of at least four months, and when a proper manner of living is pursued subsequently, complete cure may be expected in a large majority, probably 80 per cent., of the cases.

Surgical treatment of simple ulcer is capable of providing an efficient means of cure for the disease. The record of after-results or permanent cure in the cases which survive the effects of operation under surgical treatment is quite as good at the present writing, taking the grand average of cases, as that secured by medical treatment. Owing to the number of deaths which have occurred as the result of operation, the record of immediate results of surgical treatment is, however, much inferior to that obtained under medical treatment and the record of the grand total of final results, including the deaths present in the immediate results and the recurrences or failures to cure included in the record of after-results, of surgical treatment, is much inferior when we consider all the factors of benefit to the patient, the duration of life and the comparative freedom from symptoms of stomach disturbance, to that obtained under medical treatment. That is, the expectation of benefit to the patient, taking the average of all cases, is, by the verdict of the records received up to date, greater under medical treatment than under surgical.

The argument for surgical treatment in simple ulcer lies in the fact of the considerable number of recurrences which occur in medical cases, taking the average of all cases, those of individuals in good and poor circumstances, private cases and hospital cases alike, and in the deaths which result from such recurrence.

Even with this record of recurrence medical treatment is, or can be when it is thoroughly carried out, as the results prove, a satisfactory method. In the face of this efficiency of medical treatment there can be, it seems to me, no excuse for the employment of surgical treatment with its equal liability to failure to cure, and the additional chances of death, which the records show to be associated with this treatment, in place of medical treatment in the initial treatment of cases of simple ulcer. When surgery can show better average results as regards both duration of life and permanent cure it may justifiably replace medicine in the treatment of this disease. At present it is to be considered in connection with this class of cases, only in cases which have failed to find relief or have recurred after being subjected to good medical treatment.

In cases of chronic ulcer complicated with disturbance of the ability of the stomach to empty its contents into the duodenum, that is, cases of obstruction of the pylorus, or contraction of a part of the stomach wall from ulcer, causing a permanent gastrectasis, medical treatment gives very unsatisfactory results as regards the cure of the combined condition. Under such treatment patients with this affection may, in many instances, regain comfort as regards symptoms, health, strength, weight, and ability to work, and may keep this gain as long as treatment is continued. Permanent cure, that is, absence of stasis and symptoms of discomfort for an indefinite period after the cessation of treatment is, however, rarely accomplished by this means.

Surgical treatment, on the other hand, gives excellent results as regards permanent cure in this class of cases. There are, it is true, a certain number of failures to cure or of recurence symptoms, and a certain number of deaths from operation under this treatment. In a large majority of cases, however, the treatment gives excellent results, and in consideration of this latter fact, together with the fact of the inefficiency of medical treatment to provide cure for this condition, surgical treatment should, it seems to me, be advised in all cases of this type, once the diagnosis is definitely determined.

The only argument against this procedure lies in the fact that the chances of an establishment of a fair condition of health and comfort under a continued medical treatment are fairly good, and that death under such conditions is a very rare occurrence, while under surgical treatment, though the chances of cure are excellent, there is always the risk of death as the result of operation. If the patient prefers the kind of comfort which can be obtained in a life of continued treatment, there is nothing more to be said. Excellent condition can often be maintained in this way and exacting treatment is not always necessary to such maintenance. On the whole, it seems to me that, as a rule, surgical treatment is good medical advice in these cases.

For the treatment of cases of ulcer not included in the above classes, that is, cases complicated by perforation, whether the case be one of acute perforation or one in which perforation having occurred at some previous time and adhesions between the stomach wall and the surrounding tissues having been established, symptoms of stomach disturbance are still present, we have but one form of treatment, surgical treatment.

In support of these conclusions in regard to the efficiency of our modern methods of treatment of ulcer of the stomach in its various forms, I present a record of the results of treatment of the cases of ulcer of the stomach which have been under my observation and care during the last ten years. The record is made up of all cases of ulcer treated by me in private practice and such hospital cases as have been under my observation both during and after their sojourn in the hospital. Only such cases are included as have been under observation for a period of at least two years subsequent to the time of the initial treatment. Many of the cases have been followed for a much longer period.

---

* Read in the joint session of the Sections on Practice of Medicine and Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

In the first class of cases, those of simple, uncomplicated ulcer, I have included only such cases as have a record of bleeding, that is, a history of hemorrhage or a finding of blood either in the gastric contents or feces, for the reason that without such evidence (the bleeding) the existence of simple ulcer can not, save possibly in rare cases, be accurately determined, and I wish to include in my record only cases of undoubted ulcer. Cases diagnosed as ulcer at the time of the initial treatment, which have subsequently been proved to be cancer, have not been included.

In studying these records of cases of simple ulcer I have noted a fact of which I have for a long time been aware, the fact of the much greater superiority, on an average, of the results of treatment of ulcer in individuals in comfortable circumstances to those obtained in individuals of limited circumstances, as, for example, the average of hospital cases, independently of the initial severity of the cases. These results are explained, I think, by the greater facility of the first class of individuals, through their easier circumstances and their greater intelligence to carry out a thorough treatment for a long period.

It is my custom in all cases of ulcer treated medically to insist on a continuation of strict régime as to diet and rest for a period of at least four months and to advise a certain precaution as to regimen for a much longer period. This thorough regimen can not, as a rule, be carried out with strictness by poor people, the necessities of their life, the requirements of work and the lack of facilities of obtaining proper food or proper surroundings, prohibiting it. As a result they do not do as well, on the average, as their better circumstanced colleagues in misfortune.

As it is the records of those cases which thoroughly fulfill the requirements of treatment which best serve as a criterion of the efficiency of the treatment, it seems to me that the real efficiency is to be judged to a certain extent, at all events, by the results obtained in these selected cases rather than by the record of all cases. I have, therefore. included in my summary of the cases of simple ulcer treated medically, in addition to the record of all cases, a separate record of the results of the cases which received the complete regimen.

1. Cases of Simple Ulcer of the Stomach Treated Medically.—There were 51 of these cases. The immediate results were: Complete relief (cure of hemorrhage and other symptoms), 48; failure in relief of symptoms for any length of time, 2; died (from hemorrhage while under medical care), 1.

The two patients whose symptoms were not relieved were afterward operated on. Both showed evidence of a former perforation with adhesions of the stomach over the site of perforation to the anterior abdominal wall. One died shortly after operation. The other recovered from the operation by excision and has been well since.

The after-results in 49 cases were: Cured (no recurrence of symptoms within two years), 31, or 63 per cent.; recurrence (of stomach symptoms), 18, or 36 per cent.; died (from ulcer), 1, or 2 per cent.

Among the 49 patients there were 16 only who carried out the complete treatment described, that is, who continued under a strict régime as to rest and diet for four months. The remaining 33 cases remained under strict treatment for periods of from one to two months only

The record of after-results in these two sets of cases is as follows: In the 16 cases which received complete treatment there were: Cured, 13, or 80 per cent.; recurred, 3, or 18 per cent; died, 0. In the 33 cases which received treatment from one to two months there were: Cured, 18, or 54 per cent.; recurred, 15, or 45 per cent.; died, 1.

The cases included in both sets were all cases of bleeding ulcer and, on the average, of equal severity. The less good results obtained in the cases in which treatment was continued for two months only indicate, I think, not an inherent lack in the possibilities of medical treatment, but the necessity for the provision of a thorough treatment in all cases. The difference in the results in the two sets of cases was, in all probability, not due entirely to the lesser duration of strict treatment in the latter set, but in part to the fact that the patients took less good care of themselves during the period subsequent to that of the strict treatment.

2. Simple Ulcer Treated Surgically.—There were 13 cases of simple ulcer treated surgically. All were cases in which a failure to relieve symptoms or a recurrence had occurred under or after medical treatment. The results of treatment were as follows: Cured (no recurrence of symptoms within two years), 6, or 46 per cent.; recurred; not relieved by operation, 3, or 23 per cent.; died (shortly after operation), 4, or 30 per cent.

The number of surgical cases in my record is too small to allow of any definite conclusion in regard to results as compared with the results of medical treatment. These facts of importance are brought out by the record:

First, the fact that surgical treatment does serve as an efficient means of cure of simple ulcer. Thus, of the 9 cases surviving operation, 6, or 66 per cent., were completely cured.

Second, the fact that recurrence or failure to relieve symptoms does occur after operative treatment. Thus, among 9 cases which survived there were 3, or 33 per cent., of recurrence of stomach symptoms.

Third, the fact that death from operation is a not uncommon associate of surgical treatment.

3. Chronic Ulcer with Gastrectasis.—There were 26 cases of chronic ulcer with gastrectasis. The list includes only cases of chronic gastrectasis in which there was evidence that the cause of the stasis was ulcer and not cases of temporary stasis due to acute ulcer. Of the 20 cases treated medically there were: Cured (no symptoms or stasis during a long period without treatment), 0; relieved (able to avoid discomfort and keep in physical condition by constant application of medical treatment), 17, or 85 per cent.; not relieved, 3, or 15 per cent.; died under medical treatment, 0.

A number of patients after pursuing a course of treatment have been able to go for periods of from one to three months without treatment, but a return of symptoms has occurred in every instance.

The following are the results of the 14 cases treated surgically: Cured, 9, or 64 per cent.; recurrence or failure of relief, 3, or 28 per cent.; died shortly after operation, 2, or 14 per cent.

Although, as I have stated, the facts are in favor of medical treatment and against surgical procedure for the initial treatment of simple ulcer of the stomach in the average of cases, there are certain cases where this principle is not to be strictly maintained. Occasionally in practice we meet with cases of stomach disturbance in which a diagnosis of either ulcer or cancer is suggested, and in which there is reason to believe from the character and duration of the symptoms that the latter condition, if present, may be so little advanced that the complete eradication of the disease may be accomplished by surgical procedure. In such cases it seems to me that immediate operation is justifiable. It is true that only in rare instances is it possible to eradicate cancer by operation. Cases of this kind do, however, occur and it is by following this line of procedure that we are likely to find them. The following case report illustrates this point:

History.—The patient, a man aged 50, came to me in 1904. He complained at the time of a dull pain in the epigastric region present much of the time, and slightly aggravated by ingestion of food, loss of appetite and frequent desire to raise gas from the stomach. There had been no vomiting or other symptoms. There was loss of weight. The duration of the symptoms was three months at the outside.

Examination.—Physical examination other than the examination of the gastric contents showed nothing abnormal. The hemoglobin was 85 per cent. Examination of the contents of the fasting stomach, obtained by tube 12 hours after the ingestion of food, gave the following findings: Quantity, 25 c.c.; character liquid, like the white of an egg, and colorless; no food remnants were present. The guaiac test for blood was positive. Contents gave no fermentation test with glucose. Lactic acid was absent. The contents obtained one hour after an Ewald test breakfast gave the following characteristics: Quantity, 100 c.c.; food fairly digested; free HCl present, quantity low, .007 per cent.; blood present by guaiac test.

A similar finding to that given above was obtained in the fasting contents on four separate examinations. In each instance a positive blood test was obtained. No fresh blood was seen. The feces showed blood by the guaiac test.

Operation.—The case was recommended for operation with a diagnosis of either ulcer or cancer. Operation was performed by Dr. Greenough, Oct. 14, 1904. At operation a small nodule with a slight ulceration on its surface was found in the antrum pylori. No enlarged glands were found. The nodule was excised and a pyloric resection performed.

Pathologic examination of the excised mass showed the presence of carcinoma.

The patient had a good immediate recovery and in the interval of 18 months since operation has been well. He has regained his normal weight and held it, works regularly, and has suffered from no dyspeptic symptoms. In this case the early operation was advised for the following reasons: The constant blood findings showed the probable presence of ulcer or cancer. The general picture of the symptoms was more suggestive of cancer than ulcer. The short duration of symptoms suggested that if cancer were present it might be so little advanced that the disease could be entirely eradicated by operation. Whether or not the disease has been entirely eradicated is, of course, still an open question. At all events the patient has enjoyed two years of perfect health as the result of our procedure.

ETIOLOGY AND DIAGNOSIS OF GASTRIC AND DUODENAL ULCER.*

FRANK BILLINGS, M.D.
CHICAGO.

Acute gastric ulcer and the so-called abrasions of the mucous membrane of the stomach are identical in their morbid anatomy and pathology. As a rule these are superficial and extend wholly or through a part only of the mucosa. They are not uncommon and many occur in chronic circulatory disturbances due to heart and arterial disease and to cirrhosis of the liver. They may be postoperative events, especially in abdominal section. They appear in cachectic states due to chronic diseases and are not infrequent in the new born. They may appear in certain neurotic conditions, especially in women.

These acute erosions are soft, sometimes blood stained, often multiple, frequently consist of mere slits in the mucous membrane, may be so small as to escape detection and usually would not exceed 4 mm. in diameter. The largest may be dignified by the name of an ulcer. These acute processes are important only when the erosion involves an artery or vein of considerable size, when a fatal hemorrhage may occur. These acute processes will not be further considered in this paper.

ETIOLOGY.

Chronic ulcer of the stomach and duodenum, frequently termed round, perforating or peptic ulcer, follows nutritional disturbance of a limited area of the mucosa, which results in the destruction of this circumscribed region by the gastric juice. The gastric juice is the destructive agent and, therefore, plays the most important rôle in the causation of ulcer of the stomac and duodenum.

The cause of the condition which permits the gastric juice to attack a part of the mucous surface of the stomach or duodenum is not altogether clear. Probably several conditions may be important factors. It is probable that in certain instances vascular disease in the form of thrombus or embolism, with or without antecedent disease of the wall of the vessel, may be a cause. It is equally true that this condition is not present in the majority of the individuals who suffer from ulcer.

Hyperacidity of the gastric contents, with or without stagnation, is a common accompaniment of ulcer, but it is probable that it is an accompaniment and not a cause of the disease. Chlorosis has been noted in ulcer of the stomach, especially in the young female, but many cases of ulcer occur without anemia and the anemia, when present, is very frequently the result of the loss of blood incident to the ulcer. Central or pneumogastric nerve disease has been ascribed as a predisposing cause, but the evidence is not conclusive. Local ischemia from muscular spasm, especially in the pyloric region, thus predisposing the circumscribed area to destruction by the gastric juice, has been ascribed to this nervous influence. Traumatism from external violence or local traumatism from the contact of rough particles of food on the mucous membrane, and especially in the pyloric region, has been ascribed as a cause. It is known that small traumata of the normal mucous membrane heal rapidly and trauma alone is, therefore, probably not a cause. Stasis of stomach contents with decomposition has been ascribed as a cause, and it doubtless is a factor, especially when associated with bacterial infection. Bacterial infection with invasion of the mucous membrane may so reduce the nutrition of the cells as to render them liable to digestion by the gastric juice. Recently Dr. Fenton B. Turck, Chicago, has been able to produce a typical chronic ulcer of the stomach by feeding dogs with colon cultures over a considerable period of time.

Self-digestion does not occur in a healthy stomach because of a resistance of the normal cells which has heretofore been called vital. It has been suggested that this resistance is, in reality, the presence in the cells of the stomach of an antibody. Under certain conditions this antibody may disappear or may be so disturbed that it no longer protects the mucous membrane in certain localities permitting the gastric juice to attack the tissues.

---

* Read in the joint session of the Sections on Practice of Medicine and Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

To sum up our present knowledge of the cause of ulcer, it is that the gastric juice is the active agent in its production in a limited area and that this occurs because of a nutritional disturbance in a circumscribed region of the mucosa. That the nutritional disturbances may be brought about by bacterial infection associated with local trauma and that vascular disease, local areas of muscular spasm, gastric stagnation and anemia may all serve as factors in certain instances.

DIAGNOSIS.

In a classic case of ulcer there are three chief diagnostic signs. These are, in their order: pain which is usually felt in a localized area and is aggravated by a palpation and by food; second, hematemesis or melena; third, hyperchlorhydria and the some time evidences of gastric stagnation.

The pain of ulcer is characterized by the fact that it is usually felt in the localized area and that it frequently appears to the patient to pass through the body, to be felt in the back, usually on the left side near the spine at the eleventh or twelfth rib. The pain is often periodic, appearing for a day or days with severity and may be followed by an interval of less discomfort varying from days to weeks to months or even years. With the pain there is a localized tenderness which is very severe and is usually situated in the epigastrium. The pain is frequently aggravated by food. In certain instances this occurs immediately after food enters the stomach and in others not for one, two or even three hours after food is taken. The pain frequently continues until the stomach is evacuated by vomiting or until the food has passed through the pylorus. Not infrequently one obtains a history of attacks of acute exacerbations of pain extending over a period of years. These exacerbations are frequently attended with vomiting of food, with or without the appreciable appearance of blood. Frequently such patients are said to have dyspepsia, with the appearance periodically of neuralgia of the stomach.

Hematemesis and melena occur in fully one-half the cases of ulcer of the stomach. The vomited blood is usually dark in color, acid in reaction and is clotted. When passed by the bowel it is frequently tar-like in consistency and color. The occurrence of blood in vomited material and in the stool in an individual who has suffered from dyspeptic symptoms, and especially if he has had pain, is an important sign of ulcer. Occult blood may be detected in the stomach contents and in the stools from all patients who suffer from ulcer of the stomach. The appearance of occult blood usually is not constant. but will always be found if the tests are applied over a sufficiently long period of time. The Weber test for occult blood is a practical one and is reliable when safeguarded by the exclusion of the contamination of the stomach contents and of the stool, by blood from other sources, than the stomach and duodenum. The presence of iron taken as medicine and excreted in the stool will give a blue line resembling the blue line of the presence of blood when peroxid of hydrogen is used in the Weber test.

Hyperchlorhydria is present in the majority of ulcers of stomach and of the duodenum. In a small minority of patients with ulcer there may be a normal or subnormal amount of HCl or an entire absence of it in the stomach contents. In many conditions, especially neurotic in character, hyperchlorhydria exists without ulcer. Therefore, the occasional absence of hyperchlorhydria in ulcer, and the fact that it frequently occurs in neurotic conditions, makes it less reliable as a diagnostic sign in ulcer. Hyperchlorhydria with evidences of pain as indicated above and with the presence of blood, either evident or occult, in the stomach contents and the stool, however, is a positive sign of ulcer. Hyperchlorhydria with gastric stagnation and especially if the fasting stomach shows the presence of a considerable amount of acid secretion, is also of importance in the diagnosis of ulcer.

Chronic ulcer is often latent, and, if latent, one or all of the signs given above may be absent. Frequent intervals of latency follow periods which present the above symptoms. A careful investigation of the history of the patient will frequently enable one to elicit a history of attacks of acute dyspepsia associated with pain followed by intervals of latency with little or no symptoms of indigestion. In the latent state an ulcer may be partially or completely healed and the subsequent acute attack be due to a recurrence of the ulceration or to the formation of a new ulcer. In the latent period a careful examination will show, as a rule, undue epigastric tenderness; will usually show hyperchlorhydria, and, if the ulcer be unhealed, occult blood in the stomach contents and stool. Not infrequently, too, the latent condition will be accompanied with the secretion of an usual amount of acid gastric juice within the fasting stomach.

Duodenal ulcer is not infrequently associated with gastric ulcer, and its etiology is probably the same. Ulcer occurs in the duodenum between the pylorus and the papilla of the bile duct. So situated, its position is so near the pylorus that it produces practically all of the symptoms of the gastric disease, with the exception that usually melena alone and no blood vomiting occurs.

Chronic ulcers of the stomach occupy, in the great majority of cases, the pyloric half of that organ and the largest number of them appear on the posterior wall. When near the pylorus, the saddle ulcers, so called, may occur, and in some instances they may cover a very large surface. When near the pylorus they cause tonic contraction of the stomach, involving the pyloric end of the stomach with resulting stenosis. Stagnation of stomach contents results with, at first, hypertrophy of the muscle of the stomach wall. Chronic ulcer involves the deeper structures of the stomach wall and may have at its base the submucosa, the muscle or the thickened peritoneum which frequently becomes adherent to some neighboring organ. The scar resulting from partial or complete healing of an ulcer, the infiltrated and thickened wall of the stomach or pylorus and the perigastric adhesions frequently produce disturbances of motility which result in symptoms of great importance in the diagnosis of ulcer. Given a history of dyspepsia with pain, tenderness, hematemesis or melena, or of occult blood in the stomach contents and stool, hyperchlorhydria with evidences of gastric stagnation, if after a full meal the stomach does not become practically empty in seven hours and if the stagnant element is hyperacid and if it contain undigested starch cells, ulcer of the stomach or of the duodenum near the pylorus is present.

DIFFERENTIAL DIAGNOSIS.

Cholecystitis, with or without gallstones, may simulate ulcer of the stomach. Such an attack is associated with more or less severe pain in the epigastrium which may radiate to the right shoulder. There is usually marked *tenderness in the* region of the gall bladder, which, when pressed on, causes a pain which usually radiates to the epigastrium. Hyperchlorhydria may be present, but in uncomplicated cases blood is absent from the stomach contents and from the stool. With adhesions between the gall bladder, the liver and the pylorus, motor disturbances of the stomach may be present. In the interval between the attack of cholecystitis there may be some tenderness in the gall-bladder region and especially if sharp percussion be made over a limited area. This tenderness is more characteristically elicited if the stomach is first distended with gas. When cholecystitis is associated with jaundice and evidences of general infection manifested by chill and febrile disturbance, the diagnosis is more plain.

In pyloric stenosis from simple hypertrophy, there is not the severe pain of ulcer nor is there usually the frequent hyperchlorhydria of ulcer. Simple hypertrophy occurs most frequently in the new born. The differentiation of pyloric stenosis from simple hypertrophy can be made usually from the history, which will elicit the fact that the patient suffered at some time in his life with the characteristic symptoms of ulcer.

Cancer of the stomach, especially of the pylorus, may present difficulties in diagnosis, for the reason that not infrequently cancer is engrafted on an ulcer base. When this occurs the history of the patient will frequently be characterized by the symptoms of ulcer with usually a latent period preceding the development of the neoplasm. In such cases there may be the pain, the tenderness and the hyperchlorhydria of an ulcer and usually the presence of a palpable tumor. As ulcer of the stomach may cause infiltration of the stomach wall and of the pylorus to a degree which will afford a palpable tumor, the diagnosis would necessarily be in doubt in such cases. In cases of sufficiently long standing, metastatic growths in the liver and in the palpable lymph glands, especially those above the clavicle, the cachexia, the anemia and the presence of decomposing stomach contents, containing lactic and other organic acids and the Oppler-Boas bacillus, would enable one to differentiate the disease from ulcer.

NEUROSES OF THE STOMACH.

Neuroses of the stomach are very common in everyday practice. They may be associated with sensory, secretory and motor disturbances. There may be severe pain and burning, hyperchlorhydria, vomiting or spasm of cardia or of the pylorus. In uncomplicated cases, blood, both apparent and occult, would be absent from the stomach contents and feces, but the other conditions named may be so severe that it will require a study of a considerable period of time to enable one to say that ulcer is not present.

Attacks of gastric crisis in the course of locomotor ataxia have been mistaken for ulcer of the stomach. There should be no difficulty in recognizing the fundamental cord disease if a careful examination is made.

The referred pain of appendicitis may appear in the epigastrium with the association of nausea, vomiting, etc. It may be mistaken for perforating ulcer, but should never be mistaken for uncomplicated ulcer.

The Dietl phenomenon occurring with floating kidney is associated with epigastric pain, nausea, vomiting, etc. It should not confuse the observant clinician.

The abdominal and sometimes epigastric pain of pneumonia and of pleuritis will not be mistaken for ulcer by one who examines his patients.

Ulcer of the stomach and duodenum is not an uncommon disease. When the classic symptoms are present, the diagnosis can be easily made. When the disease is latent and when it is masked by conditions, the result of a neurotic temperament, the diagnosis may be difficult. Sufficiently long study of the patient and of his history, of the chemical constituents of the stomach contents, of the motility and, finally, the test for occult blood in the stomach contents and in the stool, will enable one to arrive at a definite diagnosis in most individuals.

GASTRIC AND DUODENAL ULCERS.

WHEN DO THEY REQUIRE SURGICAL TREATMENT AND WHAT PROCEDURES ARE NECESSARY?*

W. L. RODMAN, M.D., LL.D.
Professor of Surgery, Medico-Chirurgical College; Professor of Surgery, Woman's Medical College of Pennsylvania.
PHILADELPHIA.

We may say that surgical opinion has crystallized on some phases of ulcer, is crystallizing upon others and in some phases is still chaotic. The treatment of such complications as perforation and subphrenic abscess admits of no discussion whatsoever and may definitely be put to one side. Both must be met by prompt operative procedure, and it is not a question of whether to operate, but how. So far as hemorrhage is concerned there is honest room for doubt, and the variety of ulcer, its acuteness or chronicity, the amount of the hemorrhage, its recurring nature and the size of the vessel involved must be considered before a conclusion can finally and rightly be made. There is a greater difference of opinion between internists and surgeons as to the treatment of non-perforating, non-hemorrhagic ulcers with disabling adhesions and other gastric disturbances, purely mechanical in nature, following in their wake.

PERFORATION.

It is not to be questioned that spontaneous recovery may take place in perforation of either a gastric or duodenal ulcer, but in admitting the possibility of such an occurrence we should not, by accentuating it, make it appear even remotely probable.

Perforation is best considered by subdividing it into acute, subacute and chronic.

By acute perforation is understood a sudden communication between the stomach and peritoneal cavity, when the stomach is full of fluid and solid contents; extravasation necessarily occurs and the effects are usually instantaneous and overwhelming. By subacute perforation is understood a more insidious process, or, if as sudden, occurring when the stomach is empty. In either event extravasation into the peritoneal cavity will not occur, or if it does, to a most limited extent. Here a neighboring piece of omentum or coil of intestine may instantly cover the small opening made and effectually prevent extravasation. By chronic perforation a much slower and more stealthy process is understood. Here the plastic exudate limits the extravasation and a subphrenic abscess results. It should be treated by drainage, employing the abdominal, lumbar, or transpleural route, according to the preference of the surgeon and the exigencies of the case. A majority favor the abdominal route, some the combined abdominal and lumbar, while Körte, who has had a vast experience with subphrenic abscesses, prefers the transpleural route.

I have seen three unquestionable cases of subacute perforation resulting in spontaneous recovery. Two were confirmed by exploration when gastroenterostomies were subsequently done. I am of opinion that perforations acute and subacute are far more common than formerly believed and my reasons for such belief are the comparative frequency of operations at the present time for perforation in latent ulcers where the disease previously had not even been suspected. (The symptoms of ulcer are at times either so masked or completely wanting that the disease is overlooked by the best physicians). Secondly, and more to the point, demonstrable and dense adhesions are found at the site of perforation. which could not have occurred except as a result of severe perigastritis following perforation. I was both interested and amazed to find that in twelve successive gastroenterostomies performed by W. J. Mayo during ten days recently passed with him, in three cases the evidence was sufficiently convincing to this careful and judicious surgeon to cause him to record them as having previously perforated. Not less interesting is the fact that eight of the cases were operated for duodenal, three for gastric ulcer, and one for a large ulcer involving both pylorus and duodenum. The ulcer was not only found in each case but it was easily demonstrable to every one present. Duodenal ulcers are far more common than we have hitherto thought and in the Mayos' experience are practically as common as gastric. My own more limited experience leads me to the same conclusion: three of the four last operations I did were for duodenal ulcer, near the pylorus it is true, and would formerly have been designated pyloric. They are practically always within one inch of the pylorus.

---

* Read in the joint session of the Sections on Practice of Medicine and Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Chronic perforations occur on the posterior wall and at the lesser curvature of the stomach. Per contra, perforations of the acute variety are generally found on the anterior wall. In operating for perforative gastric and duodenal ulcer there are several questions to be considered and they should be decided by the exigencies of each case.

Shall the ulcer, when found, be excised? A few favor excision but a majority do not. The tissues are necrotic, uncontrollable hemorrhage may be started, and extravasation into the cavity further increased by the manipulations necessary in excising a perforated ulcer. A few interrupted Lembert's sutures, infolding the perforation, will best meet the indications if supplemented with an omental graft. If the omentum can not be utilized in this way, gauze should be used both to protect the opening and for drainage. If the extravasation has been limited mopping will suffice, drainage, however, should usually be employed. If the perforation has been acute and the general cavity has been contaminated by gross quantities of gastric contents, lavage should be thoroughly made and supplemented by suprapubic drainage. Here the Fowler position and constant irrigation of the rectum with normal salt solution, are of the greatest value. It is rarely wise to supplement suture of a perforated ulcer by gastroenterostomy. If the ulcer be at or near the pylorus, so that the infolding of the perforation results in pyloric stenosis, then, and only then, would it seem best to perform gastroenterostomy. By the time a perforation is satisfactorily closed and the toilet of the peritoneum completed the condition of the patient will not encourage, if indeed warrant, further operative measures.

Should suturing, excision, resection, or pylorectomy all be impracticable, as is occasionally the case, on account of necrotic tissues or bewildering, if not insuperable adhesions, a tube should be placed in the bowel, distal to the perforation and brought out of the stomach as in Witzel's gastrostomy. The operative results for perforation have not been as satisfactory as they should. yielding a mortality of rather more than 50 per cent. English reports 50 consecutive operations at St. George Hospital, London, with a mortality of 60 per cent. F. and G. Gross' statistics include 369 operations with 187 deaths (50.67 per cent).

These cases analysed show:

First, 12 hours, 88 cases, 22 deaths, 25 per cent.
Twelve to 24 hours, 55 cases, 29 deaths, 52.72 per cent.
Twenty-four to 48 hours, 63 cases, 36 deaths, 56.06 per cent.
After 48 hours, 31 cases, 25 deaths, 73. 91 per cent.

The best results followed operations done between the fifth and tenth hours, as the mortality was 16.25 per cent. With early diagnoses and prompt operations the mortality should, in the near future, be reduced to 15 or even 10 per cent. The extravasated gastric and duodenal contents are frequently sterile, therefore cause a less virulent and septic peritonitis than perforations of the small and large intestines, and should give better operative results. Moreover, perforations of the intestines usually occur in typhoid patients, unable to withstand both the primary shock and subsequent operative procedure.

HEMORRHAGE.

The frequency with which hemorrhage, as a symptom of gastric and duodenal ulcer is found, varies greatly according to different authorities. It is a marked symptom in at least 50 per cent. of all cases. If the gastric contents and stools were carefully examined macroscopically and microscopically from day to day the probabilities are that it would be found in nearly every case. To give some idea as to the importance of hemorrhage as a complication of ulcer we may say that in a city of 1,000,000 inhabitants, fifty thousand (5 per cent.) will suffer from gastric ulcer. Of this number one-half will bleed from time to time, and in four thousand cases (8 per cent. of those with ulcer) the hemorrhage will be lethal.

We must, so far as we can, differentiate between hemorrhages following acute and chronic ulcers, respectively. The former are not recurrent as a rule, and are usually recovered from. The diagnosis of hemorrhage, associated with acute ulcer, can generally be made, as it occurs in young anemic women in the majority of instances. It is due to a superficial erosion of the mucous membrane, the exulceratio simplex of Dieulafoy, but may be due to the perforating ulcer of Cruveilhier. The hemorrhages occur, as a rule, without warning, and while marked and causing extreme anemia in certain instances, promptly yield to medical treatment. Surgical intervention is wholly unnecessary. Of all the remedies employed for arresting such hematemeses none acts so promptly and certainly as hot water (temperature 120 to 130) introduced through a stomach tube. I have seen the best results follow its use where all other agents had proven futile and life was practically despaired of.

HEMORRHAGE FROM CHRONIC ULCER.

The bleeding from a chronic ulcer is essentially recurrent. In considerably more than 50 per cent. of all cases it is due to ulceration into a vessel of some size, namely, the splenic, pancreaticoduodenal or coronary arteries, or their arterioles, in the order named. The size of the vessel involved makes it unsafe to depend upon Nature to arrest the hemorrhage, or on simple measures which may be entirely sufficient where the oozing is from capillaries. The surgeon will usually see the case too late to act during the first hemorrhage. Should he do so, it is best to wait until the recurrent nature of the hemorrhage has been established. During a second severe hemorrhage it may be unwise to operate. As soon, however, as the patient has sufficiently recovered from shock, it is certainly best, to prevent other hemorrhages, which may now be looked on as reasonably certain. There are two ways of controlling the hemorrhage, the direct and indirect methods. In the former, the hemorrhage having been located, the bleeding point is excised, ligated, cauterized, or otherwise treated. In the latter method the stomach is made to contract, emptied of its contents and placed relatively at rest by means of a gastroenterostomy or jejunostomy. No one can doubt that the first, or direct method is more efficient and prompter. Where the ulcer can be located and there are no prohibitive adhesions, I should invariably seek to control hemorrhage by the direct method. If there is no tumor, no thinning or discoloration of the gastric walls to indicate the probable source of the hemorrhage, gastrotomy may be practiced, the entire stomach being carefully examined through a Ferguson's speculum with an electric light, and, the bleeding point, if found, treated.

Should the search prove futile, as it often will, the opening made into the stomach may be utilized in doing a gastroenterostomy, which will frequently, though not always, be sufficient to effect hemostasis. Of the direct methods of treating hemorrhage, excision or partial gastrectomy is the most satisfactory, preventing as it does future hemorrhages, perforation and malignant degeneration. Next to it I place simple gastrotomy followed by ligating the mucous membrane en masse, so as to draw up a well-marked cone after the method advised and successfully practiced by Andrews. Transfixion of the bleeding surface with careful ligation has often succeeded. Cauterization not only seems to me unsafe theoretically but has been followed by subsequent perforation in several cases. I wish to dissent most positively from the optimistic statement which has been made by those high in authority, that gastroenterostomy will surely and quickly relieve hemorrhage. A sufficient number of cases have been reported by competent and trustworthy surgeons from all parts of the world to lessen the estimate in which it has been held, if, indeed, they do not wholly discredit it as an efficient remedy. That gastroenterostomy will generally relieve capillary bleeding or hemorrhage from arterioles is likely; that it will arrest hemorrhage from a vessel of considerable size which has been eroded laterally, making contraction and retraction within its coats impossible, is to say the least, questionable.

Fatal cases of hemorrhage after apparently successful gastroenterostomies have been reported by Mayo, Deaver, Kocher, Robson, Moullin, Connell, Czerny, Rydygier, Kümmell, and many others—von Eiselsberg losing three cases and Körte two. Anatomy and pathology are not to be forgotten and it is unreasonable to expect hemorrhage from a vessel of considerable size, with a lateral opening into its caliber, to be arrested by anything short of direct surgical measures. Three months ago I operated for duodenal ulcer, performing a posterior gastroenterostomy without a loop and subsequently the patient lost one gallon of blood. I have never seen such furious hematemesis and melena. Morphia, ice and astringents failed to make any impression whatever on the bleeding, which was finally arrested, when the patient was pulseless and almost in articulo mortis, by introducing a stomach tube and pouring a pint of very hot water into the stomach. During the past 4 months there have been frequent bleedings, none of them, however, severe. They are becoming less frequent, rarely amount to more than three or four ounces and will probably cease altogether with the healing of the ulcer. She has been a difficult patient to control and could not be kept on liquid diet; in fact, has at times eaten most imprudently and nearly every attack of hematemesis has been preceded by acute indigestion caused by gross indiscretions in diet.

CURATIVE TREATMENT OF ULCER.

We now come to the treatment of ulcer itself apart from such complications as perforation, hemorrhage and subphrenic abscess. Acute ulcers, occurring as they generally do, in young anemic women, tend to heal spontaneously and should be treated strictly by medical means. Chronic ulcers, usually occurring in men past forty, show much less tendency to heal under medicinal and dietetic treatment and when they seem to do so the cure is usually not abiding. The statistics of 500 cases treated at the London Hospital show that about 50 per cent. were uncured by medical means, and of those discharged as cured, one half relapsed. The results secured at the Massachusetts General Hospital are entirely in accord with those of the London Hospital. Is it, therefore, to be wondered why an increasing number of patients with gastric ulcer tire of medical treatment and seek surgical aid. It is well to recall at this time that the mortality from the medicinal treatment of ulcer is at least 25 per cent. (13 per cent. from perforation, 8 per cent. from hemorrhage, the balance from anemia, phthisis, etc.). If we exclude acute ulcer, which, we admit, tends to heal spontaneously as a rule, it will be found that the mortality under the medical treatment of chronic ulcer is perhaps actually greater than 50 per cent. I would, therefore, insist that medical treatment in chronic ulcer be not persisted in longer than four weeks, the limit given by Leube, the most optimistic of medical men, for if it has not succeeded by this time it almost surely will never succeed. Having decided upon surgical intervention it becomes necessary to choose between methods of relief. Of these, pylorectomy, or excision of the ulcer-bearing area, partial gastrectomy, gastroenterostomy, pyloroplasty and jejunostomy may be fairly considered. If the ulcer or ulcers are situated near the pylorus, as they will be in 80 per cent. of all cases, pylorectomy, or excision of the ulcer-bearing area should undoubtedly be given the preference, provided the pylorus is free from adhesions or can easily, along with the upper portions of the duodenum, be mobilized. It alone successfully deals will multiple ulcer, gastric and duodenal, prevents perforation, hemorrhage, disabling adhesions, stricture, hour-glass contraction and malignant degeneration. Moreover, it leaves the stomach in the best condition for its future usefulness. The strongest reasons in favor of pylorectomy are the multiplicity of the ulcers and the great danger, hitherto scarcely appreciated, of cancerous implantation upon the base of the ulcer. That Hauser, who estimated that 6 per cent. of gastric ulcers subsequently became malignant understated the fact, is now generally recognized by operating surgeons of experience. I have seen two cases of cancer of the stomach within the past six months where it was next to certain that the malignant disease had been preceded by ulcer for many years. The experience of the Mayos makes it very plain that more than one-half (54 per cent.) of all gastric carcinomata operated upon at the Rochester clinic in 1905 (40 cases) were preceded by a well-marked history of ulcer and anatomic evidence of the fact was found after operation.

When it is recalled that the topography of ulcer and cancer is practically the same, each occurring at the pylorus in 80 per cent. of all cases, the conclusion is almost an irresistible one that malignant transformation must be far more common than hitherto suspected. I remember seeing three specimens presented at one meeting of the Pathological Society, of Philadelphia, where malignant transformation of benign ulcers was demonstrable. We should keep constantly before us the unpleasant fact that one-third of all carcinomata in the human subject occur in the stomach. No other organ is subject to such constant irritation which we know to be the most potent factor in transforming simple into malignant ulceration.

Operations for cancer to avail aught must be done early and the earlier the better. Is it not wiser to choose the precancerous state, if, from the symptoms presented, it is to be feared?

The other dangers of chronic ulcers are enough to warrant either excision of the ulcer or pylorectomy, which removes the ulcer-bearing area; but, the fear of malignant disease becoming ingrafted upon a benign ulceration, in a region too prone to irritation and in a soil so markedly fertile to cancer, demands radical treatment. Pylorectomy can be followed by end-to-end approximation of stomach and duodenum, where a small portion of each has been removed, or, by closure of both with independent gastrojejunostomy. The latter is usually to be preferred on account of the disparity in size between the viscera after the necessary amount of tissue has been removed. It is unnecessary to remove more than one to one and a half inches of the duodenum, for ulcers are rarely lower down.

The mortality following pylorectomy for ulcer, has been, so far as I can learn, 1 death in 31 cases. This represents the work of five surgeons (Mayo, Robson, Park, Finney and Rodman) and included all cases reported to me. A greater number will perish from perforation, as many from hemorrhage, not to mention other dangers, as stricture, hour-glass stomach, etc., which are less direct in their effect. If the ulcer is situated on the anterior wall of the stomach, in the cardiac portion and can be easily located, is circumscribed, and reasonably free from adhesions, excision or partial gastrectomy should be done. I am conscious of the fact that in advocating this plan I am opposed by the majority of American surgeons. I also admit that the existence of other ulcers may militate against a successful result, but the tendency of such ulcers to perforation is so marked and the consequences so disastrous, that it seems to me, and has ever done so, the operation of choice. The Germans generally favor the practice, many of them doing so warmly. Jedlicka calls it the normal procedure and claims for it a mortality of 5.88 per cent. When the ulcer is excised the interior of the stomach can easily be examined for other ulcers, and if they are found can be treated directly by excision or indirectly by gastroenterostomy. Where adhesions are numerous and dense, and the stomach and upper duodenum can not be easily mobilized, particularly in subjects presumably incapable of withstanding a prolonged surgical procedure, pylorectomy and partial gastrectomy should give way to gastroenterostomy, the posterior operation always, when practicable, being given the preference. The end results after posterior gastroenterostomy without a loop, now practiced by nearly all surgeons, are much better than they were several years ago, but they are not as satisfactory as the end results of pylorectomy and partial gastrectomy. It is unreasonable to expect that drainage of a stomach can either prevent or remove pathologic changes in the gastric walls.

PYLOROPLASTY.

The old methods of doing pyloroplasty have been weighed, found wanting, and are generally discredited. The operation of Finney, which he calls "pyloroplasty," but which has generally been termed by the profession gastroduodenostomy, has greater claims for recognition. It makes the anastomosis between the stomach and duodenum at the natural site, gives a larger outlet for the gastric contents and is unlikely to be followed by peptic ulcer. It has, however, contraindications, viz.: where there is much cicatricial tissue, fresh ulceration near the pylorus, or, in cases of markedly impaired gastric motility.

Jejunostomy has been extensively advocated and practiced in Germany for the relief of gastric and duodenal ulcer, with and without such complications as perforation and hemorrhage. It had the weighty endorsement of that great surgeon, Mikulicz, who advocated it in an address before the American Surgical Association, in 1903.

It seems unlikely to me that it will displace gastroenterostomy in the treatment of non-perforating and non-hemorrhagic ulcers, as it is substituting one makeshift for another and entails an amount of subsequent care and attention which are objectionable. In the treatment of perforation and hemorrhage where the direct method of dealing with the lesion is sometimes impracticable it has advantages over gastroenterostomy: First, it can be done under local anesthesia if the condition of the patient forbids a general anesthetic; second, it places the stomach wholly and not relatively at rest as does gastroenterostomy; third, its mortality is negligible.

THE MEDICAL TREATMENT OF DUODENAL AND GASTRIC ULCER.*

ALEXANDER LAMBERT, M.D.
Visiting Physician to Bellevue Hospital.
NEW YORK CITY.

To write a short discussion on the medical treatment of duodenal and gastric ulcer would have been a relatively simple task a few years ago; to-day it is far different and by no means easily performed. The difficulty arises in some degree because we realize more clearly than formerly that the course and prognosis of acute ulcer differ greatly from those of chronic ulcer, and especially because surgery has in a few years made such advances in the treatment of gastric ulcer that we must consider when medical treatment will suffice or when it is necessary for a surgeon to consider jointly what method of treatment will give the quickest and most permanent relief to the patient.

The medical treatment of duodenal ulcer being practically the same as for gastric ulcer, what is said for one will apply also for the other.

The acute and chronic gastric ulcer can not always be clinically differentiated. Often what seems to be an acute ulcer is in reality an acute exacerbation of a chronic and long-standing ulceration. The medical treatment for the two conditions is practically the same, being modified, as medical treatment is for other conditions, to meet the varying indications presented by different individuals. There is no specific for gastric ulcer, and we must rely on the normal reparative processes of the body to effect a healing, realizing that these processes are going on in an environment unfavorable to rapid and complete healing, and often in a body far below its normal condition of health.

---

* Read in the joint session of the Sections on Practice of Medicine and Surgery and Anatomy of the American Medical Association at the Fifty-seventh Annual Session, June, 1906.

The conditions to be met with are hyperacidity and sometimes hypersecretion and stasis of food in the stomach; nausea, vomiting and pain arising from the morbid processes present in the gastric mucous membrane; the general conditions and symptoms of nervousness and anemia arising from the faulty nutrition of the body; and not infrequently the complications of hemorrhage, perforation and at times stenosis and distortion of the pylorus or other regions of the stomach.

TREATMENT.

Physical Rest.—The first essential treatment is rest, complete rest for body and for stomach. This means rest in bed and rectal feeding, followed by continued rest in bed and milk diet. The length of time necessary to remain in bed varies from a week or two in acute and mild cases to several weeks in the cases of acute exacerbations of chronic ulcer. This rest cure does not mean the absolute isolation necessary in some cases of neurasthenia, but the patients must stay in bed and give up all the daily cares and worries of household and business. They may be entertained by reading and games and short visits from family and friends and may receive letters and write or dictate short replies. They must, however, remain in bed until the pain and tenderness following the ingestion of a mild but varied diet shall have disappeared. This will not average more than six weeks.

Rectal Feeding.—As soon as the general bodily rest is assured we should begin the gastric rest by complete abstension from food into the stomach; only ice and small amounts of water should be permitted, and rectal feeding begun. Each morning there should be given a high lavage of the colon with about four quarts of warm normal saline solution. After a rest of an hour the regular nutrient enemata should be begun and given at four-hour intervals during the day. Three or at most four are sufficient for the twenty-four hours. Each enema should not exceed four ounces in amount, and may consist of eggs, milk, meat broths, or meat powders, or a combination of these; but all enemata should contain only thoroughly predigested food, being thus prepared by pancreatic extracts and bicarbonate of soda. Two hours' predigestion is none too long for the preparation of these enemata. Alcohol is not an essential part of a nutrient enema and should not be given except for some special therapeutic reason, although it is a prominent ingredient of most proprietary peptone foods. About half a teaspoonful of table salt should be added to each enema. Some preparation of opium should also be added if the enemata are not well borne, or if the rectum becomes irritable from frequent use, as the rectal feeding may thus be carried on longer than is possible without it.

After a couple of days the feeling of hunger from stomach starvation becomes blunted, but the feeling of thirst is troublesome, and besides the water by mouth, about 8 oz. of saline should be injected into the bowel about an hour after the last nutrient enema in the evening has been given. The daily colonic lavage will also supply some water, as some of it will be retained and absorbed, often half a pint or even more. The patient's sleep should not be disturbed, hence rectal feeding should be omitted during the night.

Even in mild cases rectal feeding should continue for three or four days, in more severe cases for a week or ten days, and in the exacerbations of chronic ulcer some authors recommend its continuance for twenty-one days. I believe we are more sure of a cure if even in the mildest cases we carry out for some period of time exclusive rectal feeding.

Gastric Feeding.—Gastric feeding should be begun before the rectum grows intolerant; and, as we gradually increase the gastric, we should decrease the rectal feeding. Peptonized milk in small doses, given at long intervals, should be the first food given by the stomach. By increasing the amount and diminishing the intervals the average patient at the end of a week from the time gastric feeding was begun will be getting a quart of peptonized milk in twenty-four hours, with the rectal feeding discontinued. The next step is to increase the amount of peptonized milk until two quarts or more a day are given. The use of an exclusive milk diet is often objected to on the ground of personal idiosyncrasy, or because of the bitter taste of properly peptonized milk. But, as was emphasized two years ago by my brother, Dr. S. W. Lambert, when writing on this subject, if we will use the rules of modified milk as practiced in infant feeding, varying as may be necessary the amount of [illegible] milk or cream, lime water and water, and using [illegible] sugar instead of cane sugar, it is possible to obtain a milk, raw or peptonized, which will agree with any idiosyncrasy. There is, however, no epicurean or short road to the proper and palatable peptonization of milk; and the peptonized milk which we must use, whether in the colon or stomach, requires the constant application of moderate heat for two hours for its preparation, and the product has a disagreeably bitter and unappetizing taste. As soon as the patient is taking two quarts of peptonized milk a day we may begin to reduce the degree of peptonization; and usually during the third week the peptonizing process may be reduced to half an hour or twenty minutes' duration; and, by the end of another week, milk may be given raw, though perhaps still modified in strength.

As we reduce the peptonization we may add the cooked cereal gruels of barley, wheat, or oat flour as part of the diluent. During the fourth week, with the raw milk, we may add crust free bread, butter and eggs, but not hard boiled. It is well to add only one new thing at a meal that we may judge accurately if it agrees with the patient, and be ready to discontinue it if necessary. In the fifth week one may add potatoes (baked or boiled), rice (boiled), macaroni, custards, chicken and sweetbreads. In the final or sixth week of the cure, beef, mutton, green vegetables, light salad without vinegar, cooked fruits, and simple puddings may be added.

During the period in bed the patients should receive daily alcohol spongings and baths and light massage to the arms, legs, chest and back, avoiding the abdomen, to improve the general condition. Iron in some non-irritating form, as the pyrophosphate, should be given if necessary. The average patient will be out of bed in the fifth week; in the milder cases this will occur earlier. Each day from this on should see the patient doing a little more, so that before long he may resume his ordinary existence.

The Lenhartz Protein Diet.—Lenhartz recently has expressed his dissent from the abstinence diet and gives a protein diet from the first. Starting with two eggs and 6 oz. of milk on the first day, he increases the eggs one a day until eight are taken and continues at this number; the milk being simultaneously increased three ounces a day until a quart is taken and continued at this amount. The eggs and milk are given ice cold and in teaspoonful doses. On the third day two-thirds of an ounce of sugar is given, and this is gradually increased until on the ninth day 1.6 oz. are given, and this amount is continued. On the sixth day an ounce of raw scraped beef is given, double this amount on the next day, and so continued. On the seventh day 3.3 oz. of milk cooked with rice are added and gradually increased to ten ounces on the eleventh day. On the eighth day two-thirds of an ounce of zwiebach is added and gradually increased until 3.3 oz. are given on the fourteenth day. On the tenth day 1.6 oz. of raw ham are given and continued daily in this amount. Butter is also added on the tenth day, giving two-thirds of an ounce, and double this amount on the next day and continued. Lenhartz reports 60 cases treated by this method with gratifying results.

Danger of Relapse.—Whatever the diet and method of cure we pursue, after we consider our patients cured we must always remember the danger of relapse or a recurrence of the ulcer; and we must impress on them the necessity for a prophylactic diet and mode of life which we must insist they observe for a long time. These patients must avoid frequent eating and drinking and at meal times the overdistension of the stomach with food. They must eat slowly and masticate their food thoroughly. No irritating or hard foods, such as bread crusts, fruit seeds, tough vegetable or meat fibers must be given the chance to irritate mechanically the gastric mucous membrane. Alcohol in all its forms, spiced and highly cooked sauces and condiments and even excess of common salt must be avoided lest there be a chemical irritation in the stomach. As recommended by Shattuck, from three to six months after they seem well they should take before each meal from one-half to two teaspoonfuls of bismuth subnitrate. Physical and mental overfatigue must be avoided and no journeys should be undertaken on which they can not control their diet and mode of life.

Drug Measures.—Two therapeutic measures with drugs used in connection with the dietary régime deserve special mention. One is the bismuth cure, as described by Fleiner, the other the olive oil cure of Cohnheim.

1. Fleiner's Method: Wash out the fasting stomach each morning until the water returns clear and is free from all acid reaction; then introduce through the tube six ounces of water in which 2.5 to 5 drams of subnitrate of bismuth is evenly suspended. As soon as the tube is withdrawn the patient should lie down and rest quietly in such a position that the bismuth will gravitate toward the supposed site of the ulcer. After half an hour's rest the patient should be given his breakfast. The use of the bismuth should begin with the gastric feeding and continue for two weeks. Fleiner claims for this bismuth cure both an antiseptic and astringent action, besides a reduction of the hyperacidity and a mechanical protective effect of the large dose. The result of such treatment given daily should be immediately apparent in a diminution of the stomach distress and a cessation of the pain, nausea and vomiting.

Ewald has suggested the use of the insoluble carbonate of lime instead of the bismuth; and Pariser has obtained excellent results by the use of a mixture of chalk, talcum and magnesium in place of the bismuth.

2. Cohnheim's Method: Introduce olive oil through the tube into the fasting stomach after a moderate lavage, before breakfast, in quantities of from two to four ounces; or give it before the three principal meals, without the use of the tube, in doses of one to two ounces. Cohnheim claims that the oil forms a protective coating to the ulcer, relieves the pain and vomiting and tendency to pyloric spasm, allows the patient to be fed, itself acts as a food and, finally, that it checks the secretion of acid. From his reports it would seem that the milder cases can be treated under this oil regimen by simply adding a regulated diet without any rest cure.

Krausz has recently recommended a mixture of 75 grains of sodium bicarbonate in three ounces of olive oil to be given in tablespoon doses before each feeding.

Objections.—The objections urged against the bismuth and oil cure are the use of the tube in gastric ulcer. The bismuth and oil are best given by a tube, but they can and often have been given directly by the mouth. The question of the use of the stomach tube in gastric ulcer is one not always easily decided; but, if care is observed not to distend the stomach and too great pressure is prevented by limiting the height of the funnel to the head of the patient, the risk of perforation of the ulcer is slight.

But in those cases in which there has been recent hemorrhage, or if even slight hemorrhage follows the lavage, the tube should not be used. Two cases of fatal hemorrhage have been recorded, due, it was believed, solely to gastric lavage.

Other objections to the bismuth cure of constipation and discoloration of the stools, preventing the observation of malæna from slight hemorrhages, do not hold good. Large doses of bismuth do not seem to constipate, the guaiac test for blood in the feces is not obscured by bismuth and is so easily performed that it should be a routine procedure carried out at least every few days.

Silver Nitrate and Iron Perchlorid.—The principal drugs used for their astringent action and in the hope of stimulating the ulcerated surface to cicatrize are the perchlorid of iron and nitrate of silver; of these the silver is by far the most useful. To insure all the silver reaching the stomach in an active condition the solution must be given through a tube. But, if the use of the tube is undesirable, the nitrate of silver can be given in pill form in .25 to .5 grain doses, or, better still, the same dose in solution with 5 to 10 grains of bicarbonate of soda given on an empty stomach three or four times a day. The nitrate of silver acts both as an astringent and as an antacid; for, if it is precipitated as an insoluble chlorid, it uses up in the process some of the hydrochloric acid in the stomach. Boas recommends a solution of silver nitrate, four grains to four ounces of water, a tablespoonful to be taken on an empty stomach three times a day. After one bottle of this has been taken, five grains of silver nitrate to four ounces of water are given and two bottles of this strength used. Then seven grains to four ounces are given and two bottles of this taken. The nausea sometimes occurring from this medication may be corrected by peppermint, and the slight diarrhea seen at times in the beginning of the silver cure will cease spontaneously during its further administration.

The Alkalies.—Simple antacid and some laxative action is all that is usually ascribed to the alkalies, and often Carlsbad salts are given the first thing in the morning as routine treatment; but Myer, quoting Binet in a recent communication, attributes still further action to calcium phosphate, sodium bicarbonate and magnesium which, he claims, increase the gastric secretion through stimulation. This action continues up to the point of saturation of the hydrochloric acid in all three cases, but in different degrees, the action being slight after sodium bicarbonate and very marked after magnesium. Sodium bicarbonate also stimulates the motility of the stomach through the liberation of carbon dioxid. It acts on the sensibility only when pain develops a long time after eating. And such pains do not always point to hyperacidity. Often when the pain is greatest the stomach contains no free hydrochloric acid or less than is found in a test meal which has caused no pain. These pains, therefore, are dispelled more promptly by sodium bicarbonate, which neutralizes but little acid, than by magnesium and calcium, which neutralize more acid. Binet believes that this pain which develops some time after the ingestion of food is due to pyloric spasms, which are relieved by sodium bicarbonate, because of its tendency to empty the stomach through the stimulation of the motor function.

Symptoms and Complications.—In the treatment of any given case of gastric ulcer there is often a predominance of some symptom or the occurrence of some complication which demands special treatment. The nausea and vomiting and nervous symptoms are often allayed by the treatment of the ulcer itself by diet, rest and the bismuth or oil as already described. If they recur during dietary treatment, often a change back to a simpler diet will suffice to allay them again. Antiemetics are certainly not contraindicated and are often of benefit. The pain may disappear without further medication during the gastric rest with rectal feeding, or it is often allayed by the silver nitrate and sodium bicarbonate; if not, codein, cocain or anesthesin may prove effective; the relief by orthoform in my experience has been of but very short duration. Morphin will relieve, but tends to increase the gastric acidity. Hyperacidity, whether it is a cause or an effect of ulcer, is usually present and often requires attention. Frequently the simple neutralization by sodium bicarbonate is sufficient. The use of bismuth, oil and fatty foods and irrigation by silver nitrate secure the same results. Atropin or belladonna has been used successfully to control or check the secretion of the acid.

The serious complications of ulcer are perforation and hemorrhage. Perforation is a surgical condition, and one can not emphasize too strongly the urgent necessity of an operation at the earliest possible moment after the perforation has occurred. Slight hemorrhages not infrequently occur in the course of treatment of ulcer, and demand no deviation from the lines of treatment already laid down. Hemorrhage is often the first indication that a patient has an ulcer and when the amount of blood lost can be measured by ounces immediate treatment with a period of initial gastric starvation should be instituted. If the hemorrhage, even though it has been severe, is not repeated, the regular routine treatment should go on. If a considerable hemorrhage is repeated, or if there are repeated small hemorrhages sufficient to reduce the vitality of the patient, medical and surgical treatment should be discussed immediately and the physician should not look on the surgeon as the last resort. The medical measures recommended for hemorrhage are absolute rest in bed, morphin if necessary to obtain physical and mental quietude, the swallowing of ice, cold application on the abdomen, subcutaneous injections of ergot, one or two teaspoonfuls of turpentine mixed with the white of an egg and thirty drops more after an hour if necessary, and solutions of adrenalin chlorid left in the stomach by a tube, clots in the stomach being first washed out and the stomach allowed to contract.

After a severe hemorrhage the question arises whether a saline infusion should be tried. If the heart can carry on the circulation without it, it should not be given; the blood will tend to coagulate and plug the bleeding point better without it, as the infusion may wash out the plug. If it seems necessary it may be given, but only enough to enable the circulation to go on and one should be satisfied with a relatively poor pulse. Subcutaneous injections of normal saline are better, and often sufficient fluid can be absorbed by injecting 8 to 10 oz. of saline into the colon and repeating this procedure a number of times at two-hour intervals. Vigorous cardiac stimulation is certainly contraindicated.

RESULTS.

This must suffice for the medical treatment. Let us now consider its results. Taking the statistics recently published by Dr. Geo. G. Sears,[1] of this city, and adding Leube's statistics, we have 1,203 cases of gastric ulcer in which the immediate results of treatment were 88.3 per cent. cured or improved. Considering the end-results after four or five years in 647 patients, of whom such statistics are available, there is a further history of 14.2 per cent. to 37 per cent. of relapses, some patients remaining well after the relapse, 5.2 per cent. were unimproved and 5.8 per cent. died. And, finally, we have 52 per cent. as cured, 40.8 per cent. as failures, 3.6 per cent. dead of ulcer and the rest dead of intercurrent diseases. These are not encouraging statistics, but there are undoubtedly among the failures many cases which to-day would without question be sent to the surgeon. There is no question to-day that, besides perforation, all cases of pyloric stenosis and distortion of the stomach from cicatrices or perigastric adhesions belong to surgery. If we could but know how many of the medical failures belonged to these surgical classes, we could form a more accurate judgment of the value of medical or surgical treatment in those that remained.

Leaving these statistics as they stand, physicians are to-day waiting for surgical statistics of end-results from gastric surgery. Surgical literature seems more concerned with its immediate results and the perfection of its technic than in reporting the value to the patient of the operation performed. Leaving out of medical consideration, as has just been said, all cases of mechanical obstruction and distortion, there remains to be considered acute and chronic ulcer and the question of surgical interference in hemorrhage. In young individuals, suffering in all probability from acute ulcers, medical treatment has obtained its best results; and could we separate these cases from the general mass of statistics, it is my belief we would find a high percentage of actual cures.

In reviewing the results of gastroenterostomy in these cases, Clairment[2] mentions a case of perforation and death and seven fatal hemorrhages following the operation and concludes that palliative gastroenterostomy for open ulcers gives poor lasting results and does not protect the patient from the dangers of perforation and hemorrhage. If the operation does not protect against these two dangers, it is certainly wise to wait until these dangers arise and to consider acute ulcers as belonging to medical treatment until life is threatened by the acute complication. These patients are in more danger from perforation than from hemorrhage; and, even after severe hemorrhage has occurred, medical treatment will save a greater number than surgical.

In what conditions of hemorrhage, then, can the physician turn to the surgeon with a fair promise of improving the chance for life of his patient? The impossibility of locating the ulcer and bleeding point be-

2. Arch. f. Klin. Chir., vol. lxxvi, 1905.

fore operation, frequently even at operation, and the high mortality of operations performed for severe hemorrhages convince us that we are not just to our patients nor to the surgeon if we consider surgery as the last desperate chance. We will make few errors if we accept Leube's indications:

1. Repeated, little, unceasing hemorrhages, sapping the vitality of the patient, absolutely indicate early surgical interference, and all the more so if stasis is also present.

2. A simple profuse hemorrhage is not a surgical indication. But if it is repeated, an operation is relatively not absolutely indicated. An operation is only indicated if the pulse and general condition of the patient justify it.

In chronic ulcer, the condition in which most medical failures occur, does surgery offer a better chance of cure than medicine? In skilled hands the mortality of gastric surgery for ulcer to-day is about the same as in medical treatment without surgery. But, until the best operation and its technic is more generally agreed on, so that the skill of a few is more widely diffused and more statistics of end-results of operations are published, physicians can not enthusiastically adopt a surgical point of view. At present we are constrained to believe that all chronic ulcers should first be treated by a most careful and strict medical regimen; if that fails and the patients can not live in reasonable comfort or are debarred from the occupations necessary for their livelihood they should then undergo surgical procedures.

Note:—The discussion on the preceding papers in the Symposium on Causes, Diagnosis and Medical and Surgical Treatment of Gastric and Duodenal Ulcer will be published next week with the article of Dr. W. J. Mayo on surgical treatment.

CEREBRAL DECOMPRESSION.

PALLIATIVE OPERATIONS IN THE TREATMENT OF TUMORS OF THE BRAIN.

WILLIAM G. SPILLER, M.D.
AND
CHARLES H. FRAZIER, M.D.
PHILADELPHIA.

(Continued from page 751).

Case 4.—Tumor of the cerebellum or cerebellopontile angle. The tumor was not found, but great benefit was obtained by a craniotomy associated with excision of a portion of one lateral lobe.

History.—C. E., aged 23, was admitted to the University Hospital, Dec. 7, 1903, and was placed under the care of Dr. Charles K. Mills who reported that his illness began several months prior to his admission to the hospital, the principal symptoms being dizziness and intense headache, starting in the occipital region and radiating toward the forehead. Five weeks later his sight began to fail and a week later some weakness of the left arm and leg were noticed.

At the time of his admission to the hospital he was suffering from the most distressing headache, which was almost constant, and from vertigo and ataxia to such an extent that it was almost impossible for him to walk alone or without support. Nor could he even stand alone unless leaning against some stationary object. His vision was so affected that he could not see gross objects and the examination of his eyegrounds revealed the presence of very marked choked discs and optic neuritis.[35]

Operation.—The patient suffered so that it did not seem justifiable to postpone operation for further and more elaborate study of the case. Accordingly within a week of his admission to the hospital a left cerebellar craniectomy was performed by Dr. Frazier. The dura was noted to be unusually tense, and on reflecting the dural flap a considerable portion of the cerebellar hemisphere protruded through the opening. It was found to be almost impossible on account of the protrusion of cerebellar tissue to make further exploration, so the operator proceeded to remove from one-third to one-half of the lateral lobe. After this was accomplished exploration was continued, but to no avail. No tumor could be seen or felt in any portion of the left cerebellar fossa.

Subsequent History.—The postoperative record of this patient is one of unusual interest because of the remarkably rapid improvement which followed. Within one week of the operation the patient's headache had entirely disappeared, his vision was restored so that he could see minute objects on the ceiling as he lay in bed and his vertigo and ataxia had almost entirely disappeared. At no time during the convalescing period was the patient's condition such as to give any concern. He was kept under observation in the hospital for a period of two months, and inasmuch as there was not the slightest return of symptoms he was allowed to go home with the understanding that he would return to the hospital if any of his cerebellar symptoms recurred.

Present Condition.—He returned to the hospital for an examination March 5, 1906. About two years and four months had elapsed since the operation and his headache, nausea and vomiting have never recurred. His vision is practically normal and he is now engaged as a laborer in the Pennsylvania railroad shops at Altoona. It should be said, however, that he occasionally has some attacks of vertigo. His weight has increased to 184 pounds and he is in all other respects apparently perfectly well (Fig 3).

Case 5.—Tumor of the cerebrum; decompression operation affording relief from headache for a period of three years.

History.—W. D., age 22, was admitted to the University Hospital, Nov. 5, 1903, having previously been under the care of Dr. W. O. Hermance. He was admitted to the service of Dr. William G. Spiller, by whom the following history was elicited: He has been suffering from headaches since 1897 and for the past nine months they have been especially severe. He has furthermore often complained of nausea, vomiting and dizziness and his sight is completely lost.

Examination.—On examination there was found to be no involvement of either the fifth or seventh nerves. The movements of the tongue and of all the limbs were unimpaired. The biceps tendon and the triceps tendon reflexes were not specially active. The grasp of each hand was normal, as was the resistance to passive movements in all the extremities. There was no involvement of the bladder or rectum and no ataxia of upper or lower limbs. There was no deviation from normal as to stereognostic conception in either hand, the gait was normal, there was no tendency to sway or fall, there was no Babinski reflex on either side and the patellar reflexes were exaggerated. There was persistent ankle clonus on the right but none on the left side. There was no word deafness and no aphasia. His sister reported that about three months previously he was unable to speak at all for at least an hour, but that this was the only time he ever entirely lost the power of speech. He was at times delusional, and imagined he was being put into a hole. He had what he calls "sinking spells" in which he felt weak and his heart stopped beating.

About six months prior to his admission to the hospital he complained of stiffness (?), probably weakness, in the back, left side of the neck, in the left arm and left leg. He had never had any convulsions, but from April to August of the present year his whole body would get stiff for about half an hour. His memory is better than it used to be. He listens attentively to what is read to him and remembers it better than the persons who read it. The headache had been frontal and bilateral until February of this year and it seemed to have become more localized to the left temporal region.

Dr. Thorington, who had examined his eyes, reported that there were no ocular palsies, but choked disc in both eyes.

---

[35] This is Case 4, Dr. Mill's paper, "The Diagnosis of Tumors of the Cerebellum and Cerebellopontile Angle, with Special Reference to Their Surgical Removal," New York and Phila. Med. Jour., Feb. 11 and 18, 1905.

slightly more advanced in the left. There had been numerous hemorrhages, large and small, old and recent. Examination of the urine on one occasion prior to his admission to the hospital revealed a few hyalin casts and a small quantity of albumin. Since the examinations at the hospital, after repeated examinations, only on one occasion was a suspicion of hyalin casts: at no time was there albuminuria.

Nov. 5, 1903, Dr. Shumway made the following ophthalmic report: No light perception. Right eye, atrophy following choked disc. Nerve head much swollen, veins tortuous, no hemorrhages. Left eye, nerve head still more swollen, some atrophy, hemorrhage on the nasal side of the nerve, numerous white points of exudation.

Nov. 6, 1903: It was noted on this date by Dr. Spiller that pupils were dilated, there was no reaction to light and no ocular palsies. The ophthalmic reflex was present on each side. Patient closed the eyelids firmly and wrinkled the forehead well on both sides, the tongue was protruded straight, not wasted and there were no fibrillary tremors. His hearing was apparently not affected. He swallowed without difficulty. There was some tenderness to percussion over the left temporal region. There was no word deafness nor motor aphasia.

Upper limbs: Movements of the upper limbs were free at all points. The biceps and triceps reflexes hardly obtainable on either side. Grasp of each hand and resistance to passive movements were normal. Sensation for touch and pain normal in all parts of the body, and the sense of position and stereognostic conception was unimpaired. There was no wasting.

Lower limbs: Voluntary power normal, no hemiasynergy on either side and no wasting of the lower limbs. The sense of position was normal on both feet. The patellar reflexes were distinctly exaggerated on either side and more prompt on the left side. There was a slight indication of ankle clonus on the right side, although clonus was not as persistent as at the last examination. There was no clonus on the left side. The Achilles tendon reflex was exaggerated on each side, but more so on the left. The patient stood well with his feet together and the eyes open or shut. His gait was normal, although it was uncertain on account of his blindness. There was no Babinski on either side.

Further examination of the other organs including those of the thorax and abdomen proved negative.

Operation.—Craniectomy was performed by Dr. Frazier under ether anesthesia and an osteoplastic flap was reflected in the left frontal region. It was noted at the time that the skull and the dura were abnormally thick. There were no adhesions between the dura and the skull. Pulsation was visible and the brain did not bulge when the dura was reflected. Especially at the superior and anterior aspect of the opening the consistency of the brain seemed abnormally soft and an exploratory needle was introduced in various directions, but with negative results. The dural flap was replaced with sutures and the bony portion of the osteoplastic flap was removed for the purpose of relieving intracranial pressure.

Subsequent History.—The patient remained under observation in the hospital until Jan. 27, 1904, at which time it was noted that he had had no headaches since Dec. 28, 1903. His general condition had improved and he had gained in weight and strength. The last ophthalmic examination prior to his discharge from the hospital, made Jan. 1, 1904, notes that the nerve is becoming more and more atrophied.

April 15, 1904: The patient was admitted to the hospital again with a history of having had no recurrence of headache after he had been discharged; from this time on the headaches recurred generally on the right side of the head in the occipital region, accordingly it was deemed advisable to perform a second palliative operation and on April 16, 1904, Dr. Frazier performed an osteoplastic operation, reflecting a flap from the right temporo-parietal region, removing a flap 10 cm. broad and 7 cm. wide. It was noted at the time that there was no visible pulsation and that the brain appeared to be under considerable tension. The bone at the margin of the upper aspect of the opening appeared abnormally dark in color and unusually porous. An exploratory needle was introduced into the pons at about the middle of the opening but no fluid was detected.

Following the operation the patient complained for a few days of a severe supraorbital neuralgia which was attributed to the pressure which had been effected by the use of a pneumatic tube applied for the purpose of controlling hemorrhage. The patient was discharged from the hospital April 28, about two weeks after the operation. His headaches had not entirely disappeared, although they were comparatively mild in character and the patient no longer required hypodermic administration of morphia to which he had been accustomed heretofore.

Present Condition.—May, 1906: The last observation was made 2 years and 6 months after the first operation and 2 years and 1 month after the second operation, and at this time it was reported that the patient had enjoyed almost absolute relief from his headaches. He is able to perform the duties connected with the management of a cigar store and with the exception of his loss of eyesight he appears to be entirely well. The optic neuritis was so far advanced when the patient was first seen that the possibility of saving his sight was out of the question.

CASE 6.—Tumor of the cerebrum.

Patient.—M. B., aged 17, was referred to the University Hospital by Dr. R. Ross Jordan, Tyler, Clearfield County, Pa., and transferred from the service of Dr. Charles K. Mills, October 9, 1904.

History.—He was struck on the back of the head 9 months ago. He was not unconscious at the time he fell. About an hour later he became dazed, walking around aimlessly and remaining in this state for about half an hour. On Jan. 28, 1904, he was seized with shortness of breath, succeeded by tingling in the ears, and fell to the ground. It was said that during the convulsion his eyes were turned from side to side, and that the whole body with the exception of the hands and wrists fell into a state of spasm, lasting from five to seven minutes, with frothing from the mouth. Since that time he has had five attacks of this character, the latter one having been preceded by violent occipital headache and vomiting.

Examination.—He has marked optic neuritis, complains of intense headache and occasionally vomits. There is no hemiasynergia on either side. No paralysis of either facial nerve, the masseter and temporal muscles contracting well on either side. Sensation for pain and touch is equal on both sides, so that there is no involvement of either the sensory or motor root of the fifth nerve. The extraocular movements are normal, but there is a lateral nystagmus when looking from either the right or left. The tongue is protruded straight, moves freely and there are no tremors. The head is not tender to percussion.

Upper Extremities: Grasp of each hand is equal and strong; sensation for pain and touch normal in each upper limb and it is the same on both sides. Stereognostic perception is normal in both hands. Biceps and triceps tendon jerk are not distinct in either side. There is no muscular atrophy. Resistance to passive movements is normal in both upper extremities. In the lower limbs no hemiasynergia. Resistance to passive movements normal, patellar reflex normal on each side, and there is no Babinski reflex. Sensation for touch and pain are the same on both sides, gait and station are normal wih the eyes open or shut. There is not the slightest trace of hemiparesis or disturbance of sensation on the left side.

Ophthalmologic Report.—From the service of Dr. de Schweinitz: Ophthalmic diagnosis hemianopsia. Pupils react normally to light and accommodation, the muscle balance normal; eyegrounds, media clear; O. D. marked optic neuritis, 5 D. no change in macula, O. S. swelling of disc 5 D, a few small fresh hemorrhages in the fundi. No change in the macula.

Operation.—Dr. Frazier, Oct. 10, 1904. Inasmuch as the symptoms pointed entirely to a lesion in the occipital lobe, an osteoplastic flap was reflected, exposing this region. The dura exposed in the opening presented a mottled appearance as though the seat of an organized traumatic or inflammatory exudate. There was slight visible pulsation and there seemed to be considerable tension. When the dural flap was reflected the brain immediately bulged through the opening even beyond the level of the scalp. And from the opening of a jet of yellowish-red fluid spurted three or four inches. About 45 c.c. of fluid were evacuated in this way. In order to close the defect it was necessary to reflect a flap from the pericranium inasmuch as the brain still bulged considerably through the opening. This was taken from the section of bone contained in the flap and the bone itself was removed. The wound was closed with interrupted silkworm gut sutures and drain introduced through counter openings.

Subsequent History.—October 13: Since the operation the headache has entirely disappeared and the patient is now able to see objects which he could not before the operation.

October 24: On the date of his discharge from the hospital it was reported that the patient felt better than he had for some months and that the vision of both right and left eyes had improved.

R. E. V. before the operation 6/30, at the present time 6/22.

L. E. V. before the operation 6/30, at the present time 6/15.

There is still a left hemianopsia and the swelling of the discs has decreased from 5 to 3 D.

Dec. 21, 1904: The patient was readmitted to the hospital. He returned to the hospital chiefly owing to the fact that the hernia cerebri had increased and especially for the past two weeks his vision had been failing. During the past two months he had gained forty pounds. Examination of the eyeground showed that the choked disc had entirely subsided, t that there was marked optic atrophy. There was left eral hemianopsia for light only.

Dec. 23, 1904: The original field of operation was exposed and the dura was found intact. On reflecting the latter a canula was introduced and immediately a large quantity of blood-stained fluid escaped. Immediately after the evacuation of the fluid the hernial protrusion collapsed. The question arose at the time of the operation as to whether we were dealing with a cyst of the occipital lobe or the dilator horn of the lateral ventricle. No evidence could be detected of a neoplasm in the neighborhood of the operative field. The wound was closed in the usual way.

December 29: Patient has made a satisfactory convalescence from the operation. There has been a free discharge of cerebrospinal fluid from the wound, requiring reinforcement of the dressing from time to time.

Jan. 27, 1905: The patient was discharged from the hospital to-day, the wounds having healed *per primam* throughout. The hernia was not so prominent as it was before the operation. The patient's condition, with the exception of his impairment of vision, is entirely satisfactory. The optic atrophy which was discovered after the choked disc had subsided of course precludes the possibility of his recovering his vision. In a letter received from him February, 1906, the patient reports that he is feeling very well, has had no bad spells, and is now in attendance at a school in Pittsburg, Pa.

CASE 7.—Tumor of the left lateral lobe of the cerebellum. Decompressive operation, followed by striking improvement.

History.—Inasmuch as this case was reported in full,[36] it will be necessary to refer here only to the salient points.

Patient.—F. M., aged 10, was referred to Dr. Frazier's service at the University Hospital by Dr. D. J. McCarthy, March 7, 1904. The essential symptoms in the case were a gradual increase in ataxia and pronounced headache, vertigo and vomiting. There was a marked degree of choked disc on both sides.

Operation.—March 13, 1904: Dr. Frazier removed the bone overlying the left lobe of the cerebellum and proceeded to explore the hemisphere for a tumor. Exploration failed to reveal the presence of a tumor and before closing the dura, one-third of the cerebellar hemisphere was removed. The effects of the operation were most gratifying. At his discharge from the hospital on March 27 his condition was noted as greatly improved. His whole disposition had changed; he was bright and cheerful and complained neither of headache nor vomiting.

Second Operation.—November, 1904, the patient returned to the hospital because of the recurrence of some of his symptoms. On the following day the cerebellar fossa on the affected side was explored and an infiltrating tumor about the size of a walnut was found and removed.

The value of the palliative operation in those cases in which the tumor can not be localized is well illustrated by this case. Between the date of the palliative operation and the time at which the tumor was finally found and removed the patient had been comparatively free from any subjective disturbance.

CASE 8.—Suspected tumor of the cerebellum. Decompressive operation including removal of a portion of one cerebellar hemisphere, followed by considerable relief as to the vision, headache, vomiting and vertigo. Death of the patient 7 months later. No autopsy.

Patient.—P. K., aged 15, entered the neurological wards of the University Hospital in the service of Dr. William G. Spiller, May 9, 1905.

History.—Eight months ago the patient complained of headache all over the head associated with vomiting. The attacks of vomiting were irregular, sometimes twice a day and again not oftener than twice a week; in the interval, however, he was occasionally nauseated. He complained for some time also of dizziness and difficulty in locomotion. He had never had any convulsions.

Examination.—By Dr. Spiller, May 12, 1905. Conjunctival reflex is distinctly impaired on the left side; corneal reflex normal, both cornea and conjunctiva are normal on right side. Movements of the face are normal on both sides and there is no involvement of motor or sensory root of the fifth nerve. Sensation for touch and pain is not impaired. Movements of the eyeballs in all directions are somewhat impaired, and somewhat inco-ordinate. Tongue is protruded straight; there is no atrophy and there are no fibrillary tremors. Hearing for the voice appears to be normal in each ear; speech and intelligence normal. When sitting up the patient holds his head fairly erect, possibly with a little tendency to incline it to the left.

The grasp of each hand is normal, finger-to-nose test normal on each side. Neither biceps tendon reflex, triceps tendon reflex nor the wrist reflexes are distinct on either side. Sensation for both touch and pain normal in both upper extremities. There is no wasting in the upper extremities.

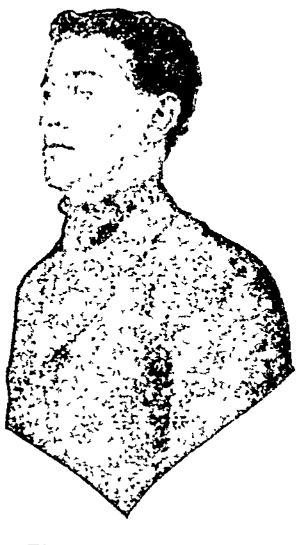

Fig. 3.—Showing the general robust appearance of patient one and one-half years after decompressive operation for tumor of the cerebellum (Case 4).

In the lower extremities the voluntary movements are normal, and there is good resistance to massive movements. The patellar reflex is very prompt, even exaggerated on the right side, but not quite so prompt on the left side. There is no ankle clonus. The Achilles jerk on the right side is prompt, but not so prompt on the left side. There is no Babinski reflex on either side, the smaller toes being drawn downward, the great toes remaining stiffer. Sensation for touch and pain is normal in each lower extremity, the cremasteric reflex is exceedingly prompt on the right side and prompt, but not so markedly so on the left. The musculature of the lower limbs is poorly developed, the patient has some difficulty in standing. On standing with his feet close together, even with his eyes open, he usually falls to the left and backwards. His gait is very ataxic with a marked tendency to go backward, and to the left. Hemiasynergy is not present on either side.

Provisional diagnosis, cerebellar tumor, more likely on the left side because of the tendency to hold the head to the left, to fall to the left and backward and because of the impairment of the left conjunctival reflex, and of the less degree of exaggeration of tendon reflexes on the left side.

May 12, 1905: Ophthalmic report by Dr. Shumway. Completely blind in the right eye, left vision about 1/100. Both pupils are widely dilated. The right pupil does not respond to light and the left responds sluggishly. There is some limitation of the movements of the eyes, particularly of inward movement, the left eye not approaching within 5 mm. of the inner angle; the movements are very jerky in character. There is a high-grade optic neuritis of the right eye which is going into secondary atrophy of the nerve. The veins are very tortuous and there is a small hemorrhage on the outer side of the nerve and an elevation of 6 D. In the left eye there is also an optic neuritis and of a milder degree with an elevation of about 4 D. The left nerve is also becoming atrophic. The patient was referred to the surgical wards.

---

[36] See Dr. Mills' paper, "The Diagnosis of Tumors of the Cerebellum and Cerebellopontile Angle, especially with Reference to Their Surgical Removal," pp. 91-96, New York and Phila. Med. Jour., February 11 and 18, 1905.

Operation.—May 17, 1905. Under ether anesthesia Dr. Frazier performed a decompressive operation. The exposure of the left cerebellar hemisphere was attended with unusually free hemorrhage particularly from those sinuses which have been described on previous occasions as existing in the occipital bone in the neighborhood of the occipital protuberance. When the dura was opened the cerebellar tissue bulged considerably but on the surface of the hemisphere and to a depth of about one inch, no pathologic condition could be demonstrated. About one-third of the hemisphere was removed and the cerebellopontile angle exposed but with negative results. A very good exposure of the seventh and eighth nerves was obtained, which were demonstrated to the eight or nine physicians who were witnessing the operation. No further exploration was made and the wound was closed.

Subsequent History.—May 6, 1905. The patient reacted from the effects of the operation. Dr. Shumway reports that the optic neuritis had subsided very much, the apex of the swelling in the right eye is now only 3 D. as compared with the 6 D. before the operation, and the left eye 2 D. as compared with 4 D. before the operation. The nerves are becoming somewhat atrophied. The patient's vision has improved particularly in the left eye, so that he can count figures at a distance of two feet.

July 19, 1905: Reported to-day that the patient can walk around the ward without any assistance, although still somewhat unsteady, but, however, no tendency to fall in any particular direction. He now has no headache, and his vision has been so improved that he is able to distinguish faces and objects.

No opportunity was afforded to make any observations after the patient was discharged from the hospital, and in answer to a letter of inquiry written in January, 1906, we learned that the patient had died December 24, 1905.

Case 9.—Suspected tumor of the cerebellum in which a decompressive operation entirely relieved the subjective symptoms.

History.—S. L., aged 20, patient of Dr. T. H. Weisenburg and Dr. M. Radcliffe was admitted to the University Hospital, Oct. 25, 1905, with the following history.

Family History.—Father died of pneumonia. Mother is living and well. Two sisters and six brothers all in good health. No history of nervous disorders, tuberculosis, renal disease, cardiac disease or neoplasm.

Social History.—Patient was born in Austria and came to this country when 3 years of age. Engineer by occupation. Uses alcohol and tobacco in moderation. Patient has a small urethral discharge at the present time of one month's duration. There is no syphilis.

Previous Medical History.—Patient had measles during infancy; otherwise he has always been in excellent health. He was well until one year ago, when he began to experience nausea, followed by vomiting with pain of a severe character, starting in the nape of the neck and shooting upward to the top of the head. At first these attacks were rather frequent, occurring every day or every other day, but they have greatly decreased in frequency. Two months ago the sight in the left eye began to fail and now he can distinguish only shadow and light. At about the same time he noticed that he was deaf in the left ear. On attempting to walk he feels giddy and staggers. This began about three or four months ago and has not increased much since then. Turning the head from side to side and backward causes some pain, but not severe. Lifting causes severe pain with blurring of vision. No motor paralysis.

Examination.—By Dr. Weisenburg. Station with eyes open and shut good. Gait with eyes closed good, though occasionally he has tendency to walk either to right or left.

Eyes: Pupils dilated with atropin. Convergence impossible with left eye, i. e., on attempting to look at nose, the left internal rectus is weakened. Associated ocular movements to right and left are perhaps affected; i. e., he can look either to right or left to the normal extent, but in a short time the eyeballs have a tendency to jerk back toward the median line. Upward and downward associated movements are normal. No diplopia. Ophthalmoscopic examination shows marked choked disc on both sides, especially the left. Both optic nerves are much swollen and hemorrhages are profuse. The appearance is that of an albuminuric retinitis.

The fifth, the seventh and the twelfth nerves are normal. Hearing seems to be diminished on the left side. There is no trouble in eating; no dysphagia; no dysphonia. Memory is good. Both upper and lower limbs are normal in form. Reflexes and sensation are normal. There is no ataxia on either side. No involvement of bladder or rectum. No hemiasynergy. Touching conjunctiva on either side does not elicit any movement of eyeball while corneal reflex is present. There is no Babinski. The results of the examination of the nose, throat and larynx by Dr. Grayson and of the sense of hearing by Dr. Randall were entirely negative.

Operation.—On Oct. 26, 1905, a decompressive operation was performed by Dr. Frazier which consisted in a suboccipital craniectomy, the bone overlying the left cerebellar hemisphere was removed. There appeared to be an increased amount of intracranial tension and the dura did not present its normal pale bluish color, but in most places and particularly in the upper and inner angle it was a yellowish opaque and dotted here and there with whitish-yellowish specks. The dura was not incised.

The operative recovery was entirely uncomplicated. The wound healed throughout *per primam.*

October 31: Dr. de Schweinitz made an ophthalmic examination and reported a right choked disc plus 10 to 11 D. left choked disc plus 9 D. and no fresh hemorrhages.

November 3: Dr. de Schweinitz reports O. D. choked disc plus 11 D., some fresh hemorrhages. Vision 6/22. O. S. choked disc plus 9 to 10 D., but more contracted laterally; fresh hemorrhage.

Dec. 23, 1905: The patient was discharged from the hospital to-day. Since the operation his vision has improved considerably.

December 22: Dr. de Schweinitz reported as follows: O. D. 6/12, subsiding neuritis plus 7 D. O. S., subsiding neuritis plus 7 D. It will thus be seen that the choked discs have subsided about 4 diopters since the operation.

Jan. 29, 1906: Patient reported at the hospital for examination and said that there had been no headache, nausea or vomiting. O. D. the disc can be distinctly seen, slight swelling of the edges, only about plus 1 D. O. S. disc apparently normal. This is one of the most striking effects on choked disc after decompressive operations that we have observed and is particularly interesting in that the results were obtained without opening the dura.

May 29, 1906: The patient now has some headache, but much less than he had before the operation. He is occasionally dizzy. The patellar reflexes are a little increased. Gait and station are good even with eyes closed. Dr. de Schweinitz reports: Subsiding optic neuritis.

R. E., marked loss of capillarity, especially temporal half, disc swollen 5 D. (eyeground 3 D) hence actual elevation 2 D: vessels shrinking, some exudate in macula. L. E., well-marked subsiding neuritis and postpapillitic atrophy.

Case 10.—Tumor of motor region.

History.—P. S., aged 25, was referred to Dr. Spiller by Dr. de Schweinitz.

Family History.—Father and mother living and well. No history of neoplasm, tuberculosis, liver or kidney disease. Cousin became insane and committed suicide. Mother says the whole family is very nervous.

Social History.—Went to school until 18 years, then studied law for three years, but was forced to give it up on account of his nervous condition, then became a fireman on a locomotive. Smokes to excess; drinks alcohol in moderation.

Note from Dr. de Schweinitz: "Double optic neuritis (choked disc) visual fields normal. No palsy of exterior muscles. Choked disc about 5 diopters."

Up to 8 years of age had almost every infectious disease. When 11 years old he went to bed well one night and awoke blind and remained so for four months (treated at St. Agnes Hospital). Sight gradually returned. According to his mother, "eyeballs were solid red, like clotted blood." To 17 years of age he had fair sight and did not wear glasses. At 17 he began to be very nervous, and it was then that he began to take "weak spells," About once a month he would suddenly become weak, his knees would give way and he would fall to the ground, but would not lose consciousness. These fainting spells disappeared after a while and have not been present since he was 18 years of age.

At 21 years of age he again wore glasses. His sight gradually diminished and he suffered severe pain in his eyes, especially behind the eyes. Temporary attacks of blindness lasting a minute or a few seconds occurred sometimes. He has always been a heavy smoker since he was 7 or 8 years old. He has averaged twenty to twenty-five cigarettes daily and also a pipe and a cigar a day. He had gonorrhea three years ago, but has not had a chancre or other venereal sore. He has been always subject to headaches, but within the past year pain has been almost constant, worse at night, preventing sleep, and associated with attacks of vertigo, weakness, nausea and vomiting. The headache is chiefly in the vertex, but sometimes occipital and above the eyes. He had a severe fall and struck on the back of his head when a child. Weakness disappears at will; if he "were to give in to it he would go in a heap." He has never had convulsions, but says that several times he has had attacks in which the whole left side, arm and leg, especially the leg, became numb, "as though dead"; the arm was only a little affected. He has no paralysis or paresis anywhere. He was a fireman on a locomotive three years and was so nervous that he gave up the work. Every little noise would make him jump, and he was always expecting something to happen, "lost his nerve," as he expressed it. Masturbated freely before 16 years of age.

Examination.—Sensation seems normal everywhere and to every form of stimulation, and there is no astereognosis and no loss of muscle sense. Ocular movements are good. Slight nystagmoid movement is seen on extreme lateral excursion, especially to the left. Reflexes are normal. There is no Babinski and no ankle clonus.

Cardiac condition: Irregular heart action without marked accentuation of either aortic or pulmonic sounds.

Patient states that the attacks of stiffness of left lower limb previously mentioned are usually preceded by much greater headache, a "sensation of something inside expanding and bursting out." They frequently occur at night, and in them the left leg becomes very rigid and is drawn across the right, but it can be voluntarily moved. The left arm is to a less extent involved and still less the left face. During the attack consciousness persists, but the whole left side feels as though "dead." He has almost constantly a blowing tinnitus aurium; only on the right side. He quit railroading in November, 1905, and since then has had only one or two attacks of spasm; previously had one or two weekly.

March 20, 1906: Yesterday morning in getting out of bed he had headache. Between 10 and 12 o'clock he became weak in his knees, but did not fall. In the afternoon he vomited and complained of intense headache and became unconscious. The left arm was flexed on the forearm and was stiff. The left lower limb was stiff and probably the left side of the face was affected. He was unconscious all night and very noisy and hard to restrain. This morning he is perfectly conscious, but in an agony of headache, crying out at times and tossing himself about in bed, clutching at any one near him and begging for relief. There is no motor weakness in any of the limbs, but he has some slight disturbance of sensation in the right hand. Stereognostic perception, the sense of position and tactile sensation are normal in each hand. The spasms which he has had have been in the left side and have always been tonic (never clonic). The patellar reflex is exaggerated on the left side and possibly slightly so on the right. Achilles tendon reflex is not exaggerated and there is no Babinski reflex.

Operation.—By Dr. Frazier, March 20, 1906. Under ether anesthesia the usual motor opening was made, the flap measuring 3½x4 inches in width and length. When the osteoplastic flap was reflected it was noticed that at a point about 2½ inches from the front of the posterior margin of the opening and just below the superior opening the dura had already been punctured by the neoplasm, and immediately overlying this point the bone had been almost entirely worn away by the tumor. There was no visible nor palpable pulsation. The exposed dura was of a greenish hue and gave the appearance as though there were beneath it numerous large vascular channels. There was a peculiar soft fluctuating sensation communicated to the examining hand. An exploratory incision was made in the dura, beginning at the point where it had ruptured spontaneously. A tumor was immediately exposed, apparently of the infiltrating character and filled with large vessels. Its removal was considered impracticable. The dural incision was closed and the lower half of the bone contained in the flap as well as considerable portion of the temporal bone was removed. The wound was closed as usual with interrupted silkworm gut sutures and the drainage introduced through two counter openings.

March 21: The headache, of which he complained so bitterly before the operation, has entirely disappeared. Patient can move his left leg, but has no movement in his left arm, forearm or fingers. Sensation is not impaired. There is some impairment of the left facial nerve.

March 22: The movements of the left lower limb are still unimpaired. The left upper limb is completely paralyzed, as is also the lower part of the left side of the face, the muscles supplied by the superior branch of the facial nerve being weak. The tongue deviates a little to the left when protruded. The left biceps and triceps reflexes are not distinct; the left patellar reflex is exaggerated. There is no ankle clonus on the left side.

Subsequent History.—March 23: Drainage removed to-day and wound in excellent condition.

March 25: Dr. de Schweinitz reports that in the right eye there is optic neuritis, a greenish-white swelling confined to the disc and covered with numerous particles, probably cholesterin. There are no hemorrhages. Swelling of the disc is plus 3 D. In the left eye the conditions are precisely similar swelling of disc plus 4 D. Vision O. D. 4/25, O. S. 4/12.

March 26: Patient's general condition is excellent. The dressing has been removed and he is up and about the ward.

March 27: For the first time the patient can lift the left arm and raise his hand over his head without any difficulty; he can flex his fingers.

March 30: Patient still has some weakness in the lower side of the face; the left upper arm is still weak, although power is gradually returning. Tactile sensation, sense of position, stereognostic conception are normal in the left hand. He is able to walk unaided.

April 1: Dr. de Schweinitz reports, under date of to-day, optic neuritis in right eye plus 3 D., in left eye plus 4 D. R. E. V. equals 4/20 (?), O. D. equals 4/10 (?). Vision is very much blurred. Evidence of temporary blindness.

April 4: The patient was discharged from the hospital today, having had absolutely no recurrence of headache.

(*To be continued.*)

A New Clinical Method of Determining Blood in the Urine.—Klimoff announces a new technic in *Russky Vrach.*, No. 16. 1906. The urine to be examined is mixed with any quantity of hydrogen dioxid and then is added a small amount of aloin powder. On shaking the mixture it turns purple. Slightly heating hastens the reaction. If the urine contains pus or is alkaline, the reaction will always be positive, whether there is blood in the urine or not, therefore the urine should be previously made acid by adding some acetic acid. The presence of albumin does not interfere with the reaction, but that of bile pigments does. With these limitations the test is reliable and sensitive.

New Appliances

TREATMENT OF FRACTURE OF THE INFERIOR MAXILLA, WITH DESCRIPTION OF A SPLINT.*

GEORGE MORRIS DORRANCE, M.D.
Assistant Demonstrator of Surgery at the University of Pennsylvania; Surgeon to the Out Patient Department of St. St. Agnes Hospital.
AND
NORMAN L. JAMESON, D.D.S.
PHILADELPHIA.

Fractures of the lower jaw are divided into fractures of the body, the ramus, the angle and the condyloid and coronoid processes. The most frequent variety is fracture of the body at the mental foramen; frequently the fracture is double, being two of the same variety or a combination of two different varieties. Numerous mechanical devices and operative procedures have been advanced for the treatment of these fractures, but, if one may judge from the numerous articles which appear each year, none give entire satisfaction. No one apparatus or operation will be satisfactory for all varieties of fracture of the inferior maxilla. The treatment of these fractures with the use of a chin cup and a Barton's bandage is antiquated and entirely unreliable, as well as being very uncomfortable. To be systematic, we will take up the different varieties in turn.

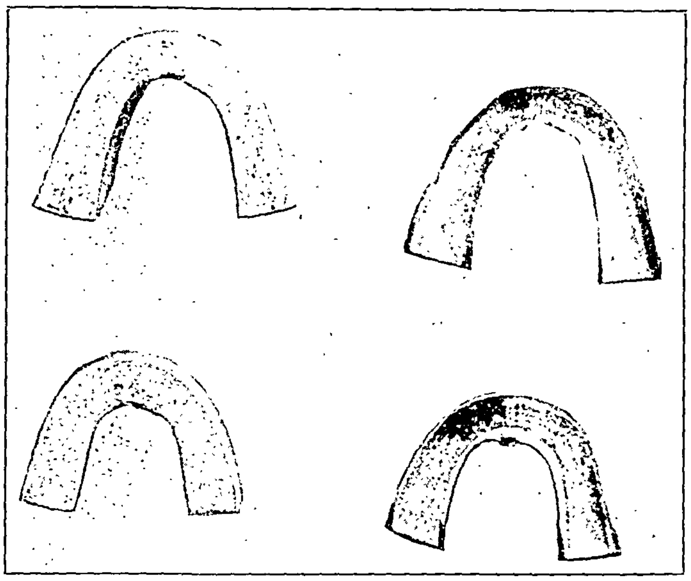

Fig. 1.—The mouth-pieces in two sizes.

FRACTURE OF THE BODY WITHIN THE ALIGNMENT OF THE TEETH.

Fractures of this variety may be treated with an interdental splint and good results obtained. The disadvantages of this method are: 1, It requires the assistance of a dentist; 2, the mouth can not be kept clean; 3, the patient can take only liquid food; 4, articulation is impossible. The Matas splint has been used by us and found very much superior to any other apparatus. but it too has several objectionable features: 1, The mouth piece bends at the slit and allows the fragments to get out of alignment; 2, the chin cup can not be adapted to the different variations in shape of the inferior maxilla; 3, all the pressure comes on the symphysis instead of being equally distributed along the body; 4, the splint extends about four inches in front of the teeth and on that account the bone is liable to be refractured; 5, the wearing of a Barton's bandage is necessary to keep it in place. To overcome these defects, we have devised the splint shown in the illustrations.

DESCRIPTION OF THE SPLINT.

This splint is constructed on the principle of a clamp. It consists of a mouthpiece, chin cup, horizontal and vertical bars and a tube which fits over the vertical bar. The mouthpiece is a horse-shoe-shaped tray resembling the impression trays used by dentists. On the center of the inner or lingual surface of the plate is a small slot for the reception of the horizontal bar. The trays are made in two different sizes (Fig. 1). From these a selection can be made to fit any jaw by ben ing the plate slightly. The chin cup is a perforated aluminu Levis cup which extends from the symphysis to the angle it is attached at the tip to the upper end of a hollow squa tube by a swivel and at its base to the lower end of the squa

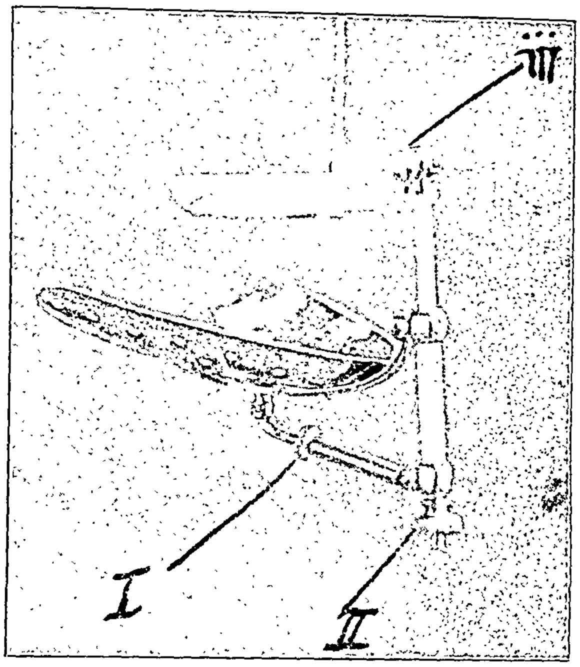

Fig. 2.—A splint for fracture of the inferior maxilla.

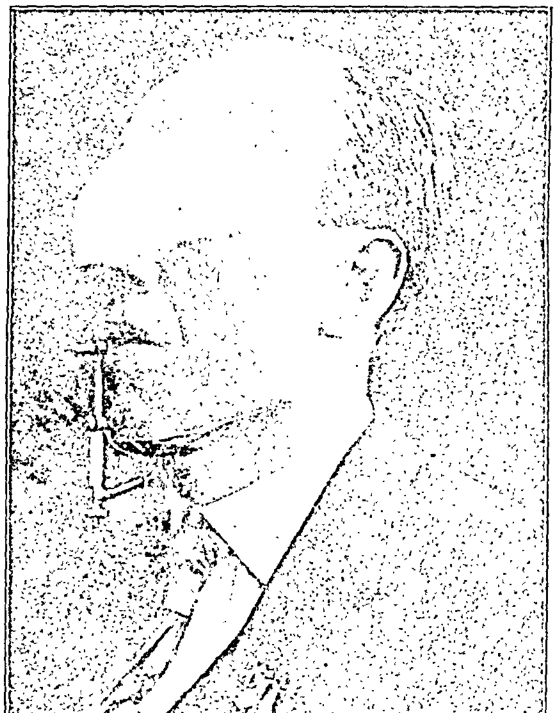

Fig. 3.—The inferior maxilla splint in place.

---

* Read before the Philadelphia County Medical Society.

tube by a jack screw, by which the chin cup can be regulated to fit any jaw from angle to symphysis (Fig. 2). The square tube fits over a square rod with a thumb screw at its lower end to regulate the pressure. The vertical square rod is pierced at its upper end by the horizontal square rod. The distance of the vertical rod from the teeth is regulated by a thumb screw at the junction of these two rods.

APPLICATION OF THE SPLINT.

The teeth should be cleaned with peroxid of hydrogen and washed with boric solution. The teeth on each side of the fracture, if they are present, should be wired together with fine brass wire to keep the fragments in apposition while the splint is being applied. Then the mouth piece, which corresponds to the size of the jaw, is bent until it accurately fits the alignment of the teeth. This plate with the horizontal rod in place is filled with modeling compound which has been softened by immersing it in hot water and is pressed down on the teeth. A few drops of cold water applied to the plate will harden the modeling compound. The chin cup and the vertical bar are placed in position and thumb screw No 1 (Fig. 2) is regulated until the chin cup fits the jaw. Then thumb screw No. 2 is regulated until the chin cup and mouth piece are held firmly together. Finally thumb screw No. 3, at the junction of the two rods, is tightened to keep the chin cup from slipping forward (Figs. 3 and 4).

The chin cup should be removed once or twice a day, the chin rubbed with alcohol and dusted with talcum powder, then the chin cup reapplied. The mouth piece should be removed and reapplied with new modeling compound every few days so as to keep the mouth clean. The pressure on the chin should be regulated so as not to cause a pressure sore.

This splint has been in use in eight cases. In every one the alignment of the teeth has been perfect.

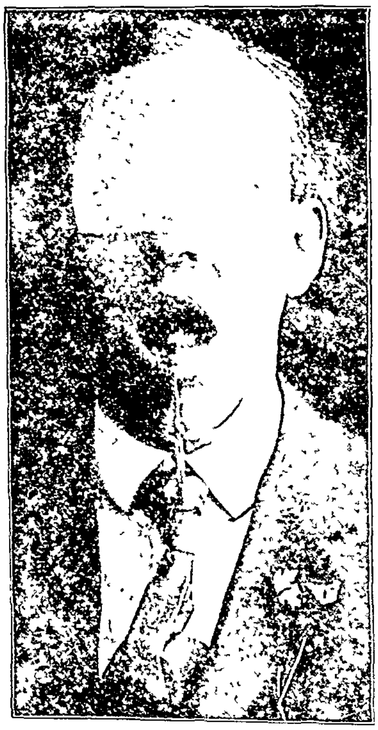

Fig. 4.—The inferior maxilla splint in place.

FRACTURES OF THE RAMUS, THE ANGLE, THE CONDYLOID AND CORONOID PROCESSES.

An interdental splint is the only appliance that will hold the fragments of the above fractures in place. Of the numerous varieties of interdental splints the one shown here is the best. The variety of interdental splint which separates the upper and lower jaws one-half an inch is only mentioned to be condemned. The use of said splint is frequently followed by inability to approximate the upper and lower jaws by reason of union taking place at an angle. When the interdental splint of German silver (Fig. 5) is used, the assistance of a dentist is required.

METHOD OF MAKING THE INTERDENTAL SPLINT.

Impressions of both sets of teeth are taken in plaster-of-Paris; from these impressions zinc dies are made, over these dies German silver plates are swaged for the upper and lower jaws. The plates are trimmed to fit around the necks of the teeth and placed in the mouth on the upper and lower teeth with a little wax between them and the jaws are closed in their proper relation. The mouth is then opened and the plate removed with the wax, holding them in apposition while being soldered together. After the teeth have been cleaned and dried, the splint with both the upper and lower plates filled with cement of a creamy consistency is placed on the upper jaw and the lower pressed up in place. A Barton's bandage should be worn until the cement is hard. The splint should be removed at the end of three weeks, the mouth cleansed and the splint put back for one week more. It is not necessary to extract a tooth to enable the patient to swallow as he can very readily take liquid food through and around the teeth.

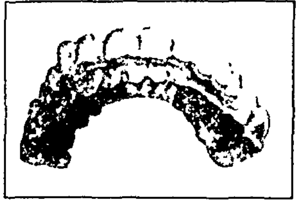

Fig. 5.—An interdental splint in German silver.

The splint shown in Figure 2 is manufactured by the Valzahn Company of Philadelphia.

MODIFICATION OF THE ESMARCH CHLOROFORM INHALER.

W. P. MEGRAIL, M.D.
WHEELING, W. VA.

This modification of Esmarch's inhaler possesses the following advantages:

1. A simple, firm and rapid method of fastening gauze or other material to the Esmarch frame by fitting the ring inside of the frame instead of on the outside, as in the old model.

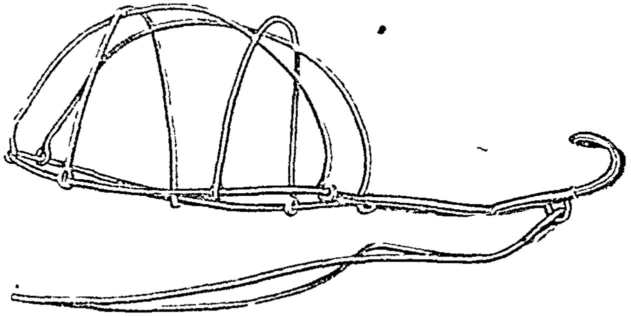

Figure 1.

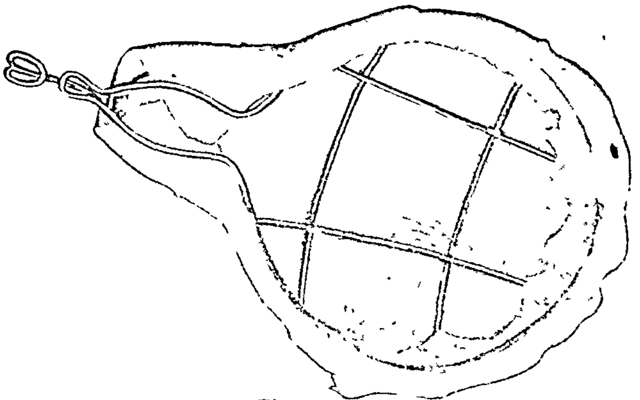

Figure 2.

2. The ring and frame are so fastened together that one can not be lost from the other, nor can they in any manner be put together wrong.

3. The patient is not annoyed by the rough edge of the gauze or metallic frame, and yet it will fit closer to the face, thereby requiring less of the anesthetic.

4. Should the gauze become soiled with vomit or sputa during anesthesia it can be almost instantly replaced with new.

New and Non-Official Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NON-OFFICIAL REMEDIES." THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

RULES GOVERNING THE ADMISSION OF ARTICLES TO THE BOOK, "NEW AND NON-OFFICIAL REMEDIES."

(The term "article" shall mean any drug, chemical or similar preparation used in the treatment of disease.)

RULE 1.—No article shall be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article be furnished for publication. The general composition of the vehicle, its alcoholic percentage, if any, and the identity of other preservatives, if present, must be furnished.

RULE 2.—No chemical compound will be admitted unless sufficient information be furnished regarding tests for identity, purity and strength, the rational formula or the structural formula, if known.

RULE 3.—No article that is advertised to the public will be admitted; but this rule will not apply to disinfectants, and food preparation, except when advertised in an objectionable manner.

RULE 4.—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to literature distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)

RULE 5.—No article will be admitted or retained concerning which the manufacturer, or his agents, make false or misleading statements as to geographical source, raw material from which made, or method of collection or preparation.

RULE 6.—No article will be admitted or retained concerning which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to the therapeutic value.

RULE 7.—Labels on articles containing "poisonous" or "potent" substances must show the amounts of each of such ingredients in a given quantity of the product. A list of such substances will be prepared.

RULE 8.—If the trade name of an article is not sufficiently descriptive of its chemical composition or pharmaceutical character, or is, for any other reason, objectionable, the Council reserves the right to include with the trade name a descriptive title in the book. Articles bearing objectionably suggestive names will be refused consideration.

RULE 9.—If the name of an article is registered, or the label copyrighted, the date of registration and a copy of the protected label should be furnished the Council. In case of registration in foreign countries, the name under which the article is registered should be supplied.

RULE 10.—If the article is patented—either process or product—the number and date of such patent or patents should be furnished.

ACETOZONE.

A mixture of equal parts of benzoylacetyl peroxide and an inert absorbent powder.

Benzoylacetyl peroxide, $C_6H_5CO.O.O.COCH_3 = C_9H_8O_4$ is made by the oxidation of a mixture of benzaldehyde and acetic anhydride.

Benzoylacetyl peroxide occurs in white, shining crystals, melting at 36.6° C. (98°F.). When heated it slowly decomposes and volatilizes. Water at 25° C. (77° F.) dissolves one part in 1,560 or 0.639 Gm. in 1,000 Cc. It is soluble in oils to the extent of about three per cent., slightly soluble in alcohol, and fairly so in ether, chloroform, and carbon tetra-chloride, though all solvents decompose it with the exception of neutral petroleum oils.

In the presence of water it undergoes hydrolysis and slowly decomposes. This change, however, does not take place with sufficient rapidity to prevent its use in aqueous solution; in fact such hydrolysis is necessary to develop its full germicidal activity. On account of its ready decomposition, acetozone should be kept in a dry place.

For various reasons it has been found necessary to add an inert absorbent powder. As found in the market, acetozone is of a grayish white color, possessing the properties of the crystalline substance, with the exception that the absorbent powder employed is insoluble.

Actions and Uses.—Benzoylacetyl peroxide belongs to a class of compounds known as the organic peroxides in which an excess of oxygen has been combined in such a way that it is somewhat slowly given off in a nascent condition. On contact with water it hydrolyzes, forming benzo-peracid and aceto-peracid which exert marked oxidizing and germicidal action. In consequence of this change, these compounds are thought to be particularly adapted for internal administration. The germicidal and antiseptic properties of this substance have been attested by the experimental results of several observers. It has been used in ophthalmic, aural and nasal practice with asserted good effects as an antiseptic. It has also been applied internally, especially in typhoid fever, with a view to the disinfection of the intestinal canal, and appears to be an intestinal antiseptic.

Dosage.—Acetozone is generally employed in aqueous solution prepared as follows: Add acetozone to warm water in the proportion of 1 Gm. to 1000 Cc. (15 grains to the quart), shake vigorously for five minutes, and allow to stand for about two hours. Decant the liquor as required. This solution may be drunk *ad libitum*. two quarts or more being taken by an adult in twenty-four hours. Acetozone is also used in oily solution as an inhalant.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S patents No. 710,005 and No. 717,016. U. S. trademark.

ACETOZONE INHALANT.

A solution of benzoylacetyl peroxide in liquid petrolatum.

Formula: One hundred grammes contain

Benzoylacetyl peroxide	1.0 Gm.
Chloretone (chlorbutanol)	0.5 Gm.
Refined liquid petrolatum	98.5 Gm.

Dosage.—It is to be inhaled in the form of a very fine spray, or nebula, best produced by an atomizer especially designed for oily liquids.

Prepared by Parke, Davis & Co., Detroit, Mich.

ACET-THEOCINSODIUM.

SOLUBLE THEOCIN.

Acet-theocinsodium, $C_7H_7N_4O_2Na + CH_3.COONa$, is a double salt of sodium acetate and 1,3-dimethylxanthinesodium (theophyllinsodium).

It is a white crystalline powder, containing about 60 per cent. of theocin. It dissolves in 23 parts of water, but is insoluble in alcohol or ether.

Actions and Uses.—It has the diuretic properties of theocin, reinforced by the diuretic action of sodium acetate, and, being more soluble, it has been claimed to be more readily absorbed and better tolerated than theophylline.

It is recommended in cardiac affections, nephritis, dropsy, etc.

Dosage.—0.2 to 0.35 Gm. (3 to 5 grains), best given after meals.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. patent.

ADNEPHRIN EMOLLIENT.

An ointment composed of the suprarenal active principle and a neutral base (1-1000).

Recommended as a local application where prolonged use is required.

Prepared by F. Stearns & Co., Detroit, Mich. U. S. trademark.

ADNEPHRIN OIL SPRAY.

A 1-1000 solution of suprarenal active principle in a neutral oil, aromatized.

The preparation is applied as a spray to the mucous membranes in congestive and inflammatory affections, preferably after washing with Dobell's solution.

Prepared by F. Stearns & Co., Detroit, Mich. U. S. trademark.

ADNEPHRIN SOLUTION.

A sterile solution (1-1000) of the suprarenal active principle in physiologic salt solution containing one-half of one per cent. of methaform (chlorbutanol).

Actions and Uses.—The actions and uses of this preparation are described under Suprarenal Alkaloid.

Dosage.—The dose internally is from 0.2 to 2.0 Cc. (3 to 30 minims) in water. Adnephrin is also used in oily solution as a spray, see Adnephrin Oil Spray, and in the form of ointment, see Adnephrin Emollient.

Prepared by F. Stearns & Co., Detroit, Mich. U. S. trademark No. 41,980.

ADRENALIN.

The active alkaloid of suprarenal gland, prepared by the method of Takamine, see Suprarenal Alkaloid.

Adrenalin is a light, white, microcrystalline powder, possessing a slightly bitter taste. On heating it turns brown at 205° C. (401° F.), melts, swells and decomposes simultaneously, at 207° C. (404.6° F.).

For Tests, Incompatibilities, Actions and Uses see Suprarenal Alkaloid.

Dosage.—Locally, 1-1000 to 1-15000 solution, as the chloride. Internally, 0.3 to 2 Cc. (5 to 30 mm.) of 1-1000 solution. Hypodermically, 1 to 15 drops of 1-1000 solution, diluted with sterile water.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. patents Nos 730,175, 730,176, 730,196, 730,197, 730,198, 753,177. U. S. trademark.

ADRENALIN CHLORIDE SOLUTION.

A 1:1000 solution of adrenalin hydrochloride in physiologic salt solution, preserved by the addition of 0.5 per cent of chloretone (chlorbutanol).

Dosage.—See adrenalin.

Prepared by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

ADRENALIN SUPPOSITORIES.

1 part of adrenalin to 1000 parts of oil of theobroma (cocao butter). Each suppository weighs about 1 Gm. (15 grains).

Prepared by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

AGURIN.

THEOBROMINE-SODIUM-ACETATE.

Agurin, $C_7H_7N_4O_2Na+NaC_2H_3O_2$, is a double salt of sodium acetate and theobromine-sodium.

It is prepared by a method similar to that used in making theobromine sodium salicylate, sodium acetate being substituted for sodium salicylate.

It is a white, finely crystalline powder, containing 60 per cent. of theobromine. It is freely soluble in water, not very readily soluble in alcohol, but more so in hot alcohol. It is quite hygroscopic, and in watery solutions gradually splits up into its components, and more readily in the presence of carbon dioxide.

It is precipitated and decomposed by carbon dioxide and by acids: it forms a bluish white precipitate with silver nitrate, a blue precipitate with copper sulphate, white with tartaremetic, red-brown with ferric salts. It is not readily precipitated by Mayer's reagent, nor by iodine.

It is incompatible with carbonated beverages, acids, saccharine and mucilaginous liquids, and most of the alkaloid reagents.

Actions and Uses.—It acts like theobromine, over which it has the advantage of great solubility and that it is well tolerated by the stomach. While inferior in diuretic power to theophyllin (which see), it is said to have greater power in sustaining the diuresis produced.

Dosage.—0.5 to 1 Gm. (7 to 15 grains), preferably in wafers or capsules. If in solution, this should be freshly prepared (with peppermint water) and without sugar or mucilage.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. trademark.

AIROL.

BISMUTH OXYIODOGALLATE. AIROFORM. BISMUTH IODOSUBGALLATE.

Airol, $C_6H_2(OH)_3(COOBiI(OH))=C_7H_6O_6IBi.$, is a combination of bismuth oxyiodide (subiodide) and gallic acid.

It is prepared by heating molecular quantities of bismuth subgallate and hydriodic acid or bismuth oxyiodide and gallic acid, in the presence of water, until a grayish-green product results, which is drained and dried.

It is a voluminous grayish-green, odorless and tasteless powder, insoluble in alcohol, ether, chloroform, and olive oil, slightly soluble in glycerin. It is practically insoluble in water, communicating to water a red color on standing, slowly in the cold, but readily when heated, being decomposed with liberation of iodine and bismuth subgallate. It is readily soluble, with decomposition, in dilute alkalies and mineral acids. It is decomposed on exposure to moist air, turning red, but in admixture with glycerin and a little water it long remains unaltered.

Airol may be identified by the appropriate tests for its components.

It is incompatible with water and calomel. It should not be exposed to moist air.

Actions and Uses.—As it liberates iodine in the nascent state in the presence of wound secretions it has been recommended as a desirable and efficient substitute for iodoform in the treatment of wounds, burns, skin diseases, gonorrhea, etc.

Dosage.—It is used externally in the pure state or diluted with talc, or in the form of a 10 per cent. suspension in equal parts of glycerin and water, or as a 10 to 20 per cent. ointment with 2 parts of petrolatum and 7 parts of wool fat.

Manufactured by F. Hoffmann-LaRoche & Cie., Basle, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). U. S. patent No. 544,101, German patents No. 80,399 and 82,593. U. S. trademark No. 26,405.

ALPHA-EUCAINE HYDROCHLORIDE.

EUCAINE HYDROCHLORIDE "A." ALPHA-EUCAINE.

Alpha-eucaine hydrochloride is the hydrochloride of benzoyl-methyl-oxypiperidine-carbonic methyl ester.

It is prepared by treating triacetonamine with hydrocyanic acid, hydrolyzing the product by boiling with water, then successively introducing the benzoyl and methyl group by treatment with benzoyl chloride and methyl iodide, purifying the synthetic base (alpha-eucaine) so obtained by crystallization from ether or alcohol, and converting it into hydrochloride by solution in dilute hydrochloric acid and crystallization:

It occurs in colorless crystalline scales or powder, neutral in reaction. It is soluble in 10 parts of cold water. Its solutions may be sterilized without change. The base is precipitated on addition of alkalies or their carbonates.

Its 5 per cent. aqueous solution yields a white precipitate with mercuric chloride, which distinguishes it from beta-eucaine hydrochloride, but not from cocaine, from which it is distinguished by a yellow crystalline precipitate produced if 3 drops of a 5 per cent. aqueous solution of chromic acid are added to 5 Cc. of a 1 per cent. alpha-eucaine solution.

It is incompatible with alkalies and their carbonates.

Actions and Uses.—The action of alpha-eucaine is similar to that of cocaine, but it is regarded as three and three-fourths times less toxic than cocaine. In large doses it first stimulates and then paralyzes the central nervous system; it slows the heart and produces a fall of blood pressure. Locally it acts like cocaine as an anesthetic, but dilates the blood vessels instead of contracting them. It does not dilate the pupil. It is more irritating to the mucous membrane than cocaine or than beta-eucaine. It has a moderate bactericidal action. It is used as a substitute for cocaine in general and minor surgery, but beta-eucaine is preferred for applications to the eye.

Dosage.—2 to 5 or even 9 per cent. solutions. Not more than 2 Cc. (30 minims) of a 4 per cent. solution should be used at one time.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin (Schering & Glatz, New York). U. S. trademark No. 28,438.

ALPHOZONE.

SUCCINIC DIOXIDE, SUCCINIC PEROXIDE, DISUCCINYL PEROXIDE.

Alphozone, $(COOH.CH_2CH_2CO)_2O_2 = C_8H_{10}O_8$, is an organic peroxide resulting from the action of hydrogen dioxide on succinic anhydride.

It is prepared by shaking 25 Cc. of a 7.5 per cent. solution of hydrogen peroxide with 10 Gm. of ordinary crystallized succinic anhydride, taking care that the temperature does not rise above 30° C. (86° F.).

It is a fluffy, white, crystalline powder, the crystals being small irregular plates. It dissolves in 30 parts of water at ordinary temperature. It is moderately soluble in alcohol, acetone, and ethyl acetate, sparingly soluble in ether, insoluble in benzene, chloroform and ligroin. Odorless or nearly so; softens at 115° C. (239° F.) and melts at 127.° C. (262° F.) with decomposition. When brought into a flame it explodes, but it does not explode on percussion or friction. It deteriorates slightly on continued exposure to air, but if kept tightly stoppered and in a dark place it remains unchanged indefinitely.

It is a powerful oxidizing agent liberating iodine from potassium iodide. It can be identified by its physical properties and its powerful oxidizing action. To test its strength add 2 Gm. of potassium iodide to 1Gm. of alphozone dissolved in 60 Cc. of distilled water. To this slowly add decinormal solution of sodium thiosulphate with constant agitation until the red brown color of the iodine is just discharged. Each cubic centimeter of sodium thiosulphate solution is equivalent to 0.0117 Gm. of alphozone. 1 Gm. of pure alphozone is equivalent to 85.41 Cc. decinormal sodium thiosulphate solution.

Actions and Uses.—Alphozone belongs to the class of organic peroxides, and by its powerful oxidizing power becomes a germicide and antiseptic.

Dosage.—Alphozone is also marketed in the form of tablets containing, each 0.065 Gm. (one grain), of alphozone, which are used for making solutions, one tablet to 60 Cc. (2 fluid ounces) of water giving a solution (1 to 1000) suitable for general external use; but, as a nasal douche, one tablet in 180 Cc. (6 fluid ounces) of water is often preferred.

Manufactured by F. Stearns & Co., Detroit, Mich. U. S. patents Nos. 768,561, 768,562 and 768,563. U. S. trademark No. 41,981.

ALUMNOL.

ALUMINUM BETANAPHTHOL-DISULPHONATE. ALUMINI NAPHTHOLSULPHONAS.

The aluminum salt of β-naphtholdisulphonic acid, $Al_2(C_{10}H_5.OH.(SO_3)_2)_3 = Al_2C_{30}H_{18}O_{21}S_6$.

It is prepared by mixing solutions of barium naphthol-disulphonate and aluminum sulphate in molecular proportions, filtering off the barium sulphate, and evaporating the filtrate to dryness.

It forms a fine, nearly white, non-hygroscopic powder, soluble in 1.5 parts of water, forming a faintly acid and slightly fluorescent solution.

It is also easily soluble in glycerin, but sparingly soluble in alcohol and insoluble in ether. When dried it loses about 9 per cent. of water, and when exposed to the air it is darkened in consequence of its reducing properties. It is precipitated from solution by albuminous and gelatinous bodies, but these precipitates are redissolved in excess of the latter bodies.

The aqueous solution (1-10) should be clear, and after acidulation with hydrochloric acid should become at most only slightly turbid, and only just tinted bluish by potassium ferrocyanide; nor should precipitates be produced in it on the addition of diluted sulphuric acid or solution of ammonium oxalate. The dried compound should yield 12.7 per cent. of ash (alumina) on incineration.

It should not be exposed to the air, and is incompatible with salts of silver, or other reducible salts.

Actions and Uses.—It is an astringent and mild antiseptic. It is claimed that it can be used as a mild astringent, an irritant or a caustic, according to the strength of the solution, and it is asserted that it exerts a peculiarly destructive action on gonococci. It has been recommended for a variety of affections in which a caustic, astringent or antiseptic is indicated. It has been particularly recommended for gonorrhea in females, especially when affecting the endometrium.

Dosage.—As a surgical antiseptic, in 0.5 to 3 per cent. solutions; in gynecology, in 2 to 5 per cent. solutions; in otology and laryngology, either as powder or in 1/4 to 1 per cent. solution as douches, washes or gargles; as cautery, in 10 to 20 per cent. solution.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M. (Victor Koechl & Co., New York). German patent No. 74,209.

AMINOFORM.

A name applied to Hexamethylenamina, U. S. P.

Sold by C. Bischoff & Co., New York.

ANESTHESIN.

PARAMIDOBENZOIC ACID ETHYL ESTER.

Anesthesin, $C_6H_4(NH_2)(COOC_2H_5)\ 1{:}4 = C_9H_{11}O_2N$ is the ethyl ester of paramidobenzoic acid, obtained by the reduction of paranitrobenzoic acid.

Paranitrobenzoic acid is obtained by the oxidation of paranitrotoluene, and this may be ethylized by the action of sulphuric acid and alcohol and the ester so obtained reduced to paramidobenzoic acid ethyl ester by the action of zinc and hydrochloric acid, or the acid may first be reduced and subsequently converted into the ethyl ester.

It is a white, crystalline powder, easily reduced to impalpability, melting at 90° to 91° C. (194° to 195.8° F.); odorless and tasteless, but producing a sensation of numbness when placed on the tongue; almost insoluble in cold and difficultly soluble in hot water; soluble in six parts of alcohol, in ether, benzene and, to the amount of 2 to 3 per cent., in fatty oils. In oil solutions it may be sterilized without decomposition, but by prolonged boiling or by warming with dilute alkalies it is split up into alcohol and paramidobenzoic acid.

It should form clear, colorless and neutral solutions in alcohol or ether; after acidification with nitric acid it should not give a precipitate with silver nitrate. Its solution in dilute hydrochloric acid (1 to 10) is not affected by hydrogen sulphide. If a few drops of sodium nitrite solution be added to the slightly acidulated aqueous solution followed by some alkaline betanaphthol solution, a cherry red coloration of bluish shade is produced, which changes to orange on further addition of hydrochloric acid. It is decomposed by prolonged heating with water and is incompatible with alkalies and their carbonates.

Actions and Uses.—It was introduced as a substitute for cocaine and is a local anesthetic, similar in its action to orthoform and said to be equally effective, but free from irritant action and toxicity. The anesthetic action, like that of the related compound orthoform, resembles that of cocaine, but is purely local, does not penetrate the mucous membranes, and in consequence of its insolubility the compound can not be used by hypodermic injection. In consequence of its insolubility the anesthetic effect is more prolonged than that of cocaine.

It is recommended in various forms of gastralgia, in ulcer and cancer of the stomach for the relief of pain, and is applied locally in rhinologic and laryngeal affections, urethritis, etc.; it is also recommended for anesthetizing wounded surfaces, burns, ulcerations and painful affections of the skin. It is more effective in cases where the skin is broken.

Dosage.—Internally, 0.3 to 0.5 Gm. (5 to 8 grains), in pastilles. Externally it is applied as a dusting powder, either pure or diluted. It may be applied as an ointment or in the form of suppositories.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M. (Victor Koechl & Co., New York). German patents Nos. K 19,416, 19,495 Anm.

ANTIPYRINE SALICYLATE.

ANTIPYRINÆ SALICYLAS. SALIPYRINE. SALAZOLON. SALIPYRAZOLON.

Antipyrine salicylate, $C_{11}H_{12}N_2O.C_6H_4OH.COOH = C_{18}H_{18}N_2O_4$, is a weak chemical combination of antipyrine and salicylic acid.

It is prepared by heating antipyrine and salicylic acid, in molecular proportions, on the water bath, allowing the oily product to congeal by cooling, and crystallizing it from alcohol.

It occurs as a white, coarsely crystalline powder, or in hexagonal tabular crystals, melting at 91° to 92° C. (195.8° to 197.6° F.); odorless, slightly sweet; soluble in 200 parts of cold and 40 parts of boiling water; readily soluble in alcohol, less readily in ether. It is decomposed by acids with the elimination of salicylic acid, and by alkalies with the elimination of antipyrine.

Its aqueous solution is rendered milky by tannic acid, then colored green by the addition of a few drops of fuming nitric acid. It is colored deep red by ferric chloride, passing to violet-red on copious dilution with water. It must not be affected by hydrogen sulphide.

It is incompatible with acids, alkalies and tannins.

Actions and Uses.—This compound possesses the properties of both antipyrine and salicylic acid and combines the analgesic power of the one with the antirheumatic action of the other. It has been used with good results in sciatica, rheumatic fevers, chronic rheumatism, influenza, pleurisy, dysmenorrhea, etc.

Dosage.—0.3 to 2.0 Gm. (5 to 30 grains) in cachets or capsules.

ANTITHERMOLINE.

A name applied to a preparation said to be made according to the following formula: Each pound contains 4000 grains of imported washed kaolin, washed and purified, 14 grains boric acid, 14 grains oil of eucalyptus, menthol and thymol combined, and 4.9 fluid ounces of glycerin. It closely resembles the Cataplasma Kaolini, U. S. P.

Prepared by G. W. Carnrick Co., New York.

ANTITHYROID PREPARATIONS.

Preparations obtained from the blood or milk of animals, after the removal of the thyroid glands.

The use of these preparations is based on the theory that the thyroid gland secretes products which are toxic, but which neutralize, and are neutralized by, other toxic substances produced elsewhere in the body. Removal of the thyroid glands, therefore, leads to the accumulation of these second toxic substances as evidenced by the phenomena of cachexia strumipriva and myxedema. On the other hand, the blood or milk of such animals is capable of preventing the effects of a hypersecretion of thyroid substance, such as is supposed to occur in Basedow's disease (exophthalmic goiter).

These views are still largely hypothetical; but the majority of clinical observers report markedly beneficial results in the milder forms of the disease and in obscure nervous disorders which are supposedly connected with thyroid hypersecretion. The effects are less pronounced in the more severe forms. The action is merely palliative and other measures of treatment should not be neglected.

Improvement occurs in two or three weeks and is indicated by an amelioration of the nervous symptoms, tremors, palpitation, insomnia and excitability.

The administration must be long continued. Oral and hypodermic administration are equally effective, but the former is usually preferred. These preparations are not toxic, even when very large doses are used.

ANTITHYROIDIN, Mœbius.

SERUM ANTITHYROIDEUM, MERCK.

The blood-serum of sheep from which the thyroid gland has been removed at least six weeks before the blood is drawn, preserved by the addition of 0.5 per cent. of phenol.

It is an amber-colored fluid, with faint odor and taste of phenol (carbolic acid). It is marketed in amber-colored vials containing 10 Cc. (2½ drams). With proper precautions, it is said to keep indefinitely.

Actions and Uses.—For actions and uses see Antithyroid Preparations.

Dosage.—It is administered by the mouth in doses beginning with 0.5 to 1 Cc. (8 to 15 min.) three times a day, gradually increasing the dose as necessary.

Manufactured by E. Merck, Darmstadt. (Merck & Co., New York.)

ARGENTAMIN.

ETHYLENE-DIAMINE-SILVER NITRATE. LIQUOR ARGENTAMINI.

An aqueous solution of silver nitrate and ethylene-diamine, corresponding to 10 per cent. of silver nitrate.

It is prepared by dissolving 10 parts each of silver nitrate and ethylene-diamine in 100 parts of water. It is a colorless, alkaline liquid, turning yellow on exposure to the light, but not precipitable by chlorides or by albumin. It is not materially injured by exposure to light, as it may be cleared by filtration.

Actions and Uses.—It is antiseptic and astringent like other silver salts, with the asserted advantage of being non-irritant and more penetrating than silver nitrate. It is said to be useful in all cases where the non-caustic action of silver nitrate is indicated.

Dosage.—It may be used in the anterior urethra in 0.25 to 1 per cent. solution; in the posterior urethra in from 1 to 4 per cent. solution; in ophthalmology in 5 per cent. solution.

Mnfd. by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin. (Schering & Glatz, New York.) German patent, No. 74,634.

ARGONIN.

CASEINSILVER. SILVERCASEIN.

A soluble casein compound containing 4.28 per cent. of silver.

It is prepared by precipitating an alkaline solution of casein with silver nitrate and alcohol. It is a fine, nearly white powder, easily soluble in water, forming an opalescent, faintly alkaline solution, which becomes clear on the addition of sodium chloride. It is also soluble in alkaline solutions, in egg albumin, blood serum, etc.

The usual reagents for silver do not affect its aqueous solution (1-20), which should remain clear on addition of sodium chloride, and should not be affected by hydrogen sulphide. On incineration, argonin should yield at least 4 per cent. of silver, which may be identified by the usual tests after solution in dilute nitric acid. It is incompatible with acids.

Actions and Uses.—Its action and uses are similar to those of silver nitrate, but it is claimed to have greater power of permeating living colloid membranes than other silver albumoses. It is applied as an injection in 0.1 to 0.2 per cent. solution; in ophthalmic practice a 10 to 20 per cent. solution in glycerin may be used.

Dosage.—It is generally used in 0.5 per cent. solution, but even 20 per cent. solutions have been injected without producing irritant symptoms.

Manufactured by Farbwerke vorm. Meister. Lucius & Bruening, Hoechst a. M. (Victor Koechl & Co., New York.) U. S. patent No. 575,277.

ARGYROL.

SILVER VITELLIN.

A compound of a derived proteid and silver oxide, containing from 20 to 25 per cent. of silver.

The so-called vitellin is said to be prepared by electrolytic decomposition of serum albumin. To this product, finely suspended in water, is added freshly precipitated, moist silver oxide and the mixture is heated under pressure until combination occurs. The liquid is then evaporated to dryness *in vacuo*. The change in the proteid is in question; probably a compound of hydrolyzed proteid (serum albumin) and silver oxide is formed.

Argyrol occurs in black glistening, hygroscopic scales, freely soluble in water and glycerin, insoluble in oils and alcohol. The solution is yellowish or black, depending on concentration, and is not affected by boiling. It gives a slight cloudiness or precipitate with sodium chloride and hydrochloric acid; on addition of ferric chloride the color is discharged with formation of a white cloud. With alkali and copper sulphate it gives a slight biuret reaction. It has a slight metallic taste. Silver is recognized in the usual way.

The compound is said to be incompatible with acids and most of the neutral and acid salts in strong solution.

Action and Uses.—Solutions of argyrol (20 to 50 per cent.) are said to be non-irritating to mucous membranes. Taken internally it is said to be non-toxic. It is claimed to be an antiseptic. It is recommended in urethritis and cystitis, in conjunctivitis and in affections of the nose, throat and ear.

Dosage.—It is employed in from 10 to 25 per cent. and even stronger solutions.

Manufactured by Barnes & Hille, Philadelphia. U. S. trademark.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue . . . . Chicago, Ill.

Cable Address . . . "Medic, Chicago"

Subscription price.........Five dollars per annum in advance

[*For other information see second page following reading matter.*]

SATURDAY, SEPTEMBER 15, 1906.

THE MEDICAL RECORD: AN ENEMY OF THE AMERICAN MEDICAL ASSOCIATION.

For many years the New York *Medical Record* was the leading medical weekly in America. Next to the *American Journal of the Medical Sciences*, it represented, better than any other journal, the best there was in American medicine. William Wood & Company, the owners, for nearly fifty years—practically since the present nominal head of the house, William H. S. Wood, in 1863, became a member of the firm—have conducted an exclusive medical book publishing business. The imprint of the firm has been on the title page of some of the best medical works this country has produced. This medical book and journal publishing business is presumed to have been and to be a paying one. The journal-publishing part, especially the *Record*, undoubtedly has been a source of a comfortable annual revenue.

The patronage of William Wood & Company, as medical publishers, came from the better class of physicians—those who read and think. Their journals have been of such a character as also to appeal to the intelligent in our profession. Under such circumstances, one would naturally suppose that they would have realized that the movements inaugurated by the American Medical Association against the nostrum evil, and for a better condition in the profession, would be endorsed by the thinking class of physicians—that is, by those to whom William Wood & Company were indebted for their success in the past and on whom they must depend for their support, as medical book publishers, in the future; hence, that they would, for policy's sake at least, have supported the Association in its laudable efforts. But they have done just the opposite.

Through their periodical, the *Medical Record*, they—or their employé—have seen fit, in four editorials, to attack the American Medical Association, its officers and its present activities. Their criticisms—if these attacks may be so dignified—ramify into every phase of the Association, its management, and its work. Their object, it is quite evident, was to discredit the officers of the Association, to reflect on the Association itself and to create dissension among its members. The animus prompting them also is perfectly plain to those who know how the subscriptions to the *Record* have been falling off and also to those who have observed the mass of nostrums in its advertising pages. The House of Delegates, the Board of Trustees and all the officers of the American Medical Association welcome honest criticism and suggestions that are made for the purpose of bettering conditions, but they resent attacks made to disrupt and to disorganize.

The editorials consist of insinuations and deliberate misstatements of facts and bear evidence of having been written by one who has little, if any, knowledge of the history of the Association, of the details of organization or of the work the Association is doing. These attacks should be ignored, but, appearing in a journal that in the past has been considered reliable, some of its readers have believed that there must have been some basis for the attacks, not realizing that the *Record* would stoop to malicious misrepresentations. Further, certain medical journals, for well-known reasons, have made all possible use of the matter. Knowing that their own outcries of "graft," "fraud" and "clique" were laughed at, they could now say, "You did not believe what *we* printed; now read what the *Medical Record* says."

It would be more satisfactory to quote *in extenso* from these editorials—for this would give our readers an idea of what they are, in which case no comment of ours would be necessary—but we have not the space. However, although the editorials were in the form of vague generalities, insinuations and inuendos, it evidently was the intention of the editor of the *Record* to have his readers accept the following propositions:

1. That the policy and the management of the American Medical Association is in the hands of a self-seeking "ring or clique."

This insinuation is constantly made by the editor of the *Record*. What evidence has he for such a statement? On what authority does he insinuate that the House of Delegates, composed of men elected from every state and territory in the Union and changing its membership every two years, is or can be dominated and controlled by a few men for their own purposes? Such a charge is absolutely false, is supported by no evidence whatever and is a direct insult to the representatives of the profession, who are chosen by their fellow physicians to administer and protect their interests. Never, in the history of the American Medical Association, was there assembled a more representative, fearless and independent body of men than that composing the House of Delegates at Boston.

2. That the "financial reports of the American Medical Association have been disquietingly analogous to those of insurance companies and have dealt in glittering generalities."

Had the solicitude of the editor of the *Record* regarding the affairs of the American Medical Association extended over a longer period than that of his own incumbency of his present exalted position, he would be aware that the reports of the Board of Trustees for the last few years have been far more complete and more detailed than at any other period of the Association's existence. We recommend to the editor of the *Record* a casual perusal of the Association's proceedings, not only for the current year, but for preceding years, before he attempts to misinform his readers.

3. That there is, in the minds of honest and intelligent members of the organized profession, a suspicion of "graft;" that the accounts of the Association have been "juggled;" that "more than 23 per cent. of what should have been received in dues and subscriptions remains unaccounted for."

This also is untrue, and, furthermore, it is an infamous libel on the members of the Board of Trustees, who have, without one cent of pay and at a sacrifice of their own time and professional work, looked after the business of the Association. The members of the board are men of high rank in the profession and of unblemished personal character. On what grounds does the editor of the *Record*, by covert insinuation and baseless inuendo, attempt to question their integrity? The standing of each of them is as much above suspicion as the editor of the *Record* could possibly wish his own to be. What evidence or proof has he to justify him in attacking honorable members of his own profession? As a gentleman and a member of a scientific brotherhood, it is incumbent on him either to retract his statements or to produce such evidence as will justify his malicious utterances.

4. That the House of Delegates at Boston was dissatisfied with the report of the Board of Trustees and that it was denied details regarding the business of the Association.

This statement every member of the House of Delegates knows to be false. The report of the Board of Trustees was adopted by an unanimous vote. During the reading of the report, the complete pay-roll, showing every cent paid in salaries and wages to the 150 and more employés of the Association, from the Editor to the errand boy, was submitted to the House. Detailed statements, covering every item mentioned in the auditor's report, were submitted, or were ready for the information and inspection of the members of the House. We fear the *Record* was not very well served by its Boston representatives and we suggest that hereafter more reliable and accurate data be secured as the basis for future attacks. Incidentally, we are constrained to ask by what right the *Medical Record*, or its owners, the commercial house of William Wood & Co., demand the publication of the pay-roll of the American Medical Association for the scrutiny and information of any and all commercial interests. Is such a list published by any fraternal organization, by any company or by any corporation anywhere?

5. That the surplus of the American Medical Association is nearly a quarter of a million dollars.

The editor of the *Record* has perpetrated the sophomoric error of confusing surplus with assets. The actual surplus, as shown by the auditor's report, published in THE JOURNAL, was $60,084.21. The assets of the American Medical Association, as set forth in the same report, were, on Jan. 1, 1906, $247,482.91, but the editor of the *Record* failed to note, or was unable to grasp the fact, that this included real estate and buildings, furniture and machinery, stock and cash on hand, as well as bills and accounts receivable. We have the statement of the editor of the *Record* himself made some months ago, that "the editorial and the business departments of the *Record* are absolutely separate." If his conception regarding the surplus is to be taken as a sample of his financial ability, we can not but commend the foresight of William Wood & Co. in making such an arrangement.

6. That the Treasurer of the Association, to whom the editor of the *Record* sarcastically refers as a "prominent bank director and successful financier," is responsible for the investments of the surplus of the Association.

The most superficial acquaintance with the Constitution and By-Laws of the American Medical Association would have shown the editor of the *Record* that the Treasurer is simply the custodian, under heavy bonds, of the surplus funds of the Association, which he holds subject to the order of the Board of Trustees. The Trustees themselves, and not the Treasurer, are responsible for the investment of the surplus funds of the Association.

7. That the Association has become so big "that the number of papers presented in the various sections is too great to permit of their being assimilated by the hearers, or profitably discussed."

If our self-appointed critic had been in touch with the section work, he would have known that there have been for the last four or five years fewer papers than ever before; that sixty, seventy or eighty papers in a section was not an uncommon thing in years gone by; that now, by a general law, the number is limited to forty and that some of the sections have fixed a still lower limit, some as low as twenty-five. As the editor of the *Record*, so far as we know, never attended a session of the Association, he is excusable for this misdirected criticism.

8. That there is no need of the proposed medical directory; that the proceeds of the directory will increase the income of the Association to half a million dollars; that the sales of the book to non-members and the profits of the advertising will pay the cost of production and that the publication of the American Medical Directory is absolutely without excuse.

The consideration of the Directory demands a chapter by itself, which we propose soon to present to our readers. Suffice it to say at this point that the editor of the *Record* either has no conception of the objects of the Directory and what it will stand for, or else purposely ignores them. These matters have been fully discussed in THE JOURNAL time and again. In THE JOURNAL, Nov. 18, 1905, for instance, appeared a detailed statement of the plan and scope of the work, which evidently the editor of the *Medical Record* has never read. This, however, is no excuse for his ignorance. His profound suggestion that the Association give away twenty thousand—now it would be twenty-six thousand—copies of the Directory to its members is too puerile for comment. We once more pause to congratulate William Wood & Co. that their editor has no connection whatever with the business department of the *Record*.

9. That there is "loudly expressed dissatisfaction with the present management all over the country, which is assuming definite form in the organizing of new state medical societies and even serious talk of a rival national organization."

Will the editor of the *Record* kindly name any state in which a new state medical society is being organized? The Association office is presumed to know the actual conditions regarding medical organization throughout the country. But, evidently, this presumption is unfounded. The *Record* has discovered a condition that was not known to exist. Now, what are the facts? Never before was there less opposition to the plan of organization than now prevails in every state and territory, all but two being organized on a uniform basis. Until two years ago, there was opposition in several states; now there is practically none. In Georgia, immediately after the reorganization of the State Association, there was some disaffection on the part of a few physicians and some transient agitation for the organizing of another state society, but this amounted to nothing. In one county in Michigan, six dissatisfied physicians agitated the organization of a new state body, but nothing definite resulted. This movement was never looked on seriously by those connected with the state society. The disaffection in both instances was the result of purely local conditions in no way related to the American Medical Association and was merely a remnant of the disaffection that at one time prevailed in many states. Never has the profession been more united, never before has it been so influential, never have there been so few local jealousies, and never has there been a more hopeful outlook in every way than now.

10. That the Walker resolution, introduced at the Boston session, was defeated through the efforts of the officers or the Board of Trustees or their friends, and that an attempt was made to suppress an investigation of the business affairs of the Association.

Again, we are led to deplore the inaccuracy of the reports received by the *Record*. The facts are these: The moment the reading of the resolution was concluded, it was at once tabled by the practically unanimous vote of the House. There was no discussion. The members of the House cared for none. There was no time for the officers to express themselves even had they desired to do so. The statement that the resolution was opposed by the officers, the trustees or their friends is an absolute falsehood, unless the entire membership of the House of Delegates is included under the designation "friends." The Association and its officers are fighting secrecy and deception and are not practicing it.

11. That at Boston "a strenuous effort was made to get rid of the Editor, and that so great has become the dissatisfaction with his administration that this endeavor might have been successful had the general body any voice in the management of the Association."

This statement is unqualifiedly false, as all who attended the Boston session well know. There was an opposition, it is true, and a bitter one, but it was limited to the horde of nostrum vendors who have been getting rich by humbugging and deceiving our profession, and to the owners or attachés of those medical journals nourished by the same brood, who allow themselves to be used as the mouthpieces and tools of proprietary interests. The Editor of The Journal of the American Medical Association knows full well that he is hated with a most intense hatred by these gentlemen and their allies, and that they would stop at nothing to secure his "dismissal," but he also knows, and knows thoroughly and well, that the "management" was fully and completely endorsed by 95 per cent. of the physicians at the Boston session, and, for that matter, is endorsed by a like proportion of the physicians of the country, who know the truth of what is going on.

So much for the "facts" regarding the American Medical Association as set forth by the editor of the *Record*. Just a word as to that gentleman himself. He graduated in the spring of 1877 and so has been a member of the medical profession for 29 years. During all this time, his interest in the American Medical Association and in medical organization was so great and his enthusiasm so uncontrollable that in March, 1906, just ten weeks before the Boston session, he became a member of the American Medical Association. Truly, not without reason has the zeal of the new convert become proverbial. Had he devoted a small part of the 29 years of his professional life to a more careful study of the organization of which he was, at last, to become a member, he might have been able to discuss the Association's affairs intelligently, if not truthfully. During all this time, men whose membership in the organization numbers years while his numbers weeks were earnestly and unselfishly striving, not only to build up the American Medical Association, but to bring about better conditions in our profession. During the same time, what has the editor of the *Medical Record* done in this respect? Yet he now arrogates to himself the right to criticise and, by implication and by baseless insinuations to brand these same men as "boodlers" and "grafters."

Is it probable that the business interests of an old and hitherto reputable publishing house will be enhanced by the use of its journal as a medium for such malicious, unfounded and unwarranted attacks? We think not. However, we commend this thought to the consideration of William Wood & Co. of New York.

TREATMENT OF TYPHOID FEVER.

A brief review of the opinions expressed with regard to the treatment of typhoid fever at the recent meeting of the British Medical Association will have special value at this season, not only because the subject is always a live one, but because of the different points of view of our British colleagues. There is little difference of opinion to be reported, but many of the ideas expressed in the discussion deserve notice because of their practical character. Two phases of the treatment of typhoid fever received special attention, and these may well be called the eternal questions in typhoid fever, the problem of removing harmful infectious material from the intestines, and that other ever-recurrent question, What shall the typhoid-fever patient be fed?

The declaration that the bowels of typhoid-fever patients should be kept rather loose, so as to prevent the retention of large numbers of bacilli in the intestinal tract and the consequent absorption of large amounts of the toxic material excreted by these bacilli, was not received with favor. It was pointed out both by our English and Canadian confrères that typhoid patients who are somewhat inclined to be constipated do better than those whose bowels are loose. A distinguished English authority said that the only cases of typhoid fever in his practice about which he became anxious were the sufferers from diarrhea. These patients fall victims to intestinal hemorrhage and perforation much more frequently than those who are constipated. In a large number of cases the mortality among those who had diarrhea was more than twice as great as among those who were more or less constipated.

It was further pointed out that the presence of the bacilli is evidently not a matter to be feared. Patients recover from typhoid fever, gain rapidly in weight and apparently enjoy the best of health, yet continue to excrete typhoid bacilli for many months. It must not be forgotten that these bacilli can be found in the urine of patients often for three months and sometimes for much longer, yet there is no bad effect from them, except the possibility of infection to others, and the patient is sometimes actually in better health than before the attack. The effort of the physician, then, who wishes to help Nature in the struggle with the disease must be not merely to encourage the removal of as many bacilli as possible, but to help Nature with the production of that immunity to the typhoid bacilli which eventually occurs in all persons who recover. The few bacilli that might be removed from the intestinal tract by means of purgatives are as nothing compared to the many millions of those organisms that continue to pass from the system after the patient has become thoroughly convalescent.

The rational treatment of typhoid fever, then, consists in the promotion of immunity. There are no direct means for this, but indirectly the best remedial measure is evidently to preserve the patient's strength as much as possible in order to encourage a healthy reaction. In securing this object the question of how typhoid-fever patients must be fed becomes important. There is practically universal agreement now that an exclusive milk diet—except for patients who are very fond of milk and who can take large quantities of it without disturbance—is a mistake. During the first week of typhoid fever, patients rarely crave any food, and only small amounts should be given. As soon as they begin to develop an appetite, however, additions should be made to their diet, and the extent of these additions was the special subject of discussion. Several, even of the most conservative, of British physicians declared that they considered it advisable to give a patient almost anything he asked for. This is, of course, to be followed only as far as the more nutritious classes of foods are considered. All kinds of fruit juices are to be permitted, though the greatest care must be exercised in the removal from them of seedy particles or anything else that, failing to be digested, might prove irritant to the typhoid ulcers. Some would allow all kinds of meat if asked for, provided the meat was given in a very fine state of division.

It was agreed that it is very difficult to decide just what is the meaning of solid food. Milk unmixed with barley water or with arrowroot will often, in the words of Sir Thomas Barlow, be found in the intestine in large craggy masses which certainly must prove a serious cause of irritation to the typhoid ulcers. On the other hand, finely minced meat will become thoroughly fluid under normal conditions of digestion. In normal circumstances only indigestible food remains in solid condition as low down as the terminal portion of the ileum. It would seem advisable, then, to feed patients much more liberally both as regards quantity and variety than has been hitherto the custom, first in order to shorten the stay in the hospital, an important consideration for workingmen, and, second, in order to prevent the occurrence of the sequelæ of typhoid fever, such as abscesses of various kinds and thromboses, which were shown by statistics to be much more frequent after typhoid fever treated with an exclusive milk diet than when treated with a more generous and varied diet.

THE PHARMACOLOGY OF "SOMNOS."

About a year ago "Somnos," a proprietary preparation put out by the H. K. Mulford Company, was taken up by the Council on Pharmacy and Chemistry. Preliminary examination showed that it was a preparation of chloral, probably a solution of a weak compound of chloral and glycerin. The advertising literature sent out by the H. K. Mulford Company was worded in such a way as to hide from physicians the real nature of the preparation, but, instead, stress was laid on the claim that it was free from chloral. The attention of the officers of the company was called to the matter, and it was hoped that they would submit a plain statement regarding the composition of the preparation and modify the literature to conform with the actual facts. This they did not seem inclined to do, at least they did not do it.

The Council having become satisfied regarding the actual composition of Somnos, a subcommittee was asked to investigate its physiologic action and to compare this with that of chloral so that the claims made by the manufacturers regarding its therapeutic action might be verified or disproved. These investigations were conducted last April and May, and the report has been ready since that time, but has been withheld, awaiting the action of the H. K. Mulford Company. By reference to The Journal, two weeks ago,[1] it will be seen that the H. K. Mulford Company, in a roundabout way, has acknowledged that Somnos is a combination of chloral and glycerin, but it still persists in claiming that "the product is safer than any known hypnotic, that it produces normal sleep, is less depressing than the bromids and absolutely without any untoward effect on the heart, respiration and vasomotor centers or the blood."

For the reason that the old claims regarding the therapeutic action and safety of Somnos were persisted in, the report of its pharmacology was ordered published. It will be found in this issue.[2] This report may not make interesting reading to the average physician, since it is more or less technical. Nevertheless, it is to be hoped that physicians have become sufficiently interested in the great question which is affected by this report to get at least the sum and substance of it. Condensed into a few words, the experiments show conclusively that the combination of chloral and glycerin, put out by the H. K. Mulford Company as "Somnos," is *practically identical in its physiologic action with a solution of hydrate of chloral containing a similar quantity of the drug, that it is fatal in the same relative doses, and that the company has made claims for its preparation which, look at the matter as we may, are extravagant in the extreme.*

It is to be regretted that a reputable pharmaceutical house such as the H. K. Mulford Company should have stooped to such practices. To say the least, it has not been honest and square in this matter. It has made claims for its preparation as a therapeutic agent that would be considered fraudulent in the extreme were they made regarding a "patent medicine."

While criticising the H. K. Mulford Company, however, we regret to say that it is not the only firm of standing that has been guilty of such practices, as may be shown hereafter. There are many preparations manufactured and sold by pharmaceutical houses of standing which are exploited under false claims, either as regards their composition or their therapeutic action, or both. It is to be hoped that the Council will not be obliged to make public *the actual facts* regarding these preparations, but that the manufacturers themselves will conclude to be honest and square with our profession and state the facts themselves, or withdraw the articles from the market.

The object of the Council is to bring about better conditions for the future, not to punish for past misdeeds.

PHYSICAL BASIS OF LIGHTNING DREAD.

The mortality statistics of the last five years show t the average annual number of deaths from lightni was more than 200. The report of these sad accide is read with terror, yet with avidity, by many pers who have an inordinate dread of lightning, and the c sequence is an increase of their lightning phobia, that toward the end of the summer a thunder sto becomes a source of positive dismay. It is usually c sidered that such persons have an unreasoning dread lightning, but an analysis of cases soon shows that m of them are sensible persons under ordinary conditio though they lose all their confidence in themselves alm at the first sign of a lightning storm.

There is no doubt now in the minds of those who h studied a number of those cases closely that the dre of lightning is a true phobia, though there is in it v probably much more of a physical basis than there is the most of the unreasoning dreads which are call phobias. While the sufferers from mysophobia, the f of dirt, which makes people wash their hands dozens times a day, have the excuse that it is because they dre the presence of microbes that they wash so frequently, is well known that such cases occurred long before t present state of acute attention to microbes so charact istic of our day developed. There is here simply an i perative idea that they must not let themselves be co taminated by dirt, an idea from which they can not away. Most of the other phobias are of the same distinctly psychic character and can be overcome only by suggestion, though, as a rule, the amelioration of the person's health brings about an improvement in the annoying symptoms. In all of these cases there is a distinct condition of what used to be called neurasthenia, though in recent years there has come to be a very general realization that, owing to the preponderance of the mental element in these cases, the term psychasthenia or phrenasthenia is much more expressively descriptive.

It seems clear, however, that there is something in the physical condition of the elements just before and during a thunderstorm which affects certain people very unfavorably. It has been suggested that the disturbance of the ether which causes telegraphic instruments to be less easily used than before and which so seriously disturbs long-distance telephone lines may have its effect also on the brain neurons. That the neurons may affect and also be affected by vibrations in the ether is well recognized. When as president of the British Association for the Advancement of Science some years ago Sir William Crookes took "Telepathy" for the subject of his address, he suggested as the only possible explanation for certain well-recognized phenomena of the communication of minds at a distance from one another, the traveling of impulses from one set of neurons through the circumambient ether to the other set. Only such minds can thus communicate as have the same moment of vibration, just as only such wireless telegraphic stations can communicate with each other as have their sending and receiving instruments properly attuned to each other.

---

[1] The Journal, September 1, page 695.

[2] See page 872.

It would seem that the minds of persons who suffer from a great fear of lightning become primarily affected by the magnetic disturbance in the ether which sympathetically is communicated to their neurons. In spite of every reasoning, then, a panicky condition develops to a great extent beyond the control of the will. Under these circumstances reassurance is given to such persons by a straightforward explanation of the reason for their phobia in the physical affection which exists in the underlying basis of mental operations. This proves a very valuable suggestion of therapeutic value even in the worst cases. In some individuals it becomes almost curative in effect, even though the physical dread of lightning does not disappear. It has been suggested that this method of mental therapeutics would save a great deal of suffering in many cases.

NEW AND NON-OFFICIAL REMEDIES.

The first installment of the list of proprietary articles approved by the Council on Pharmacy and Chemistry appears in this issue. It is expected that an installment will appear each week for some months, or until all the articles that have been approved shall have been announced. It is understood that this publication in The Journal is preliminary to the publication in book form. It will be noticed that the Council asks for suggestions and criticisms, especially from physicians. The object is to supply our profession with reliable information regarding proprietary medicines, and in such a way that it will be a help to physicians in deciding not only whether or not a preparation is worthy of confidence, but also to aid them in judging of its therapeutic value. Hence, if our readers feel that the matter can be put in a form more useful to them, they should submit their views to the secretary of the Council. It is now over a year and a half since the Council was organized; some may wonder why so long a time has been necessary before the profession could have the benefit of its deliberations. Those who realize the actual conditions that faced the Council at the beginning, the important problems to be solved, the immense amount of work inseparable from an undertaking of this magnitude, will not wonder that so much time has passed before actual work, as far as the approved preparations are concerned, is made public. Further, the Council has realized that any false step might cause criticism and bring about a failure at the very outset; consequently, extraordinary care has been observed so that no steps should be taken that might have to be retraced.

THE WEST VIRGINIA MEDICAL JOURNAL.

The most recent addition to the state journals is the *West Virginia Medical Journal,* which, with its August number "with its very best bow, steps modestly into the charmed circle of state medical society journalism, and hopes for a warm welcome." There is little fear that it will be disappointed, as it covers a territory in which a clean, ably edited and aggressive state journal is greatly needed. The first number, carefully edited and well printed, appears in magazine form, 7 x 9¾, with fifty pages of reading matter mainly devoted to papers read at the last annual meeting of the state association, together with the minutes of the House of Delegates and news from county societies. The number also contains a complete alphabetical list of the members of the state association. The new journal is in the hands of a committee on publication, consisting of Drs. S. L. Jepson, L. D. Wilson and John L. Dickey, all of Wheeling, and is printed in Wheeling. We feel sure that the members of the West Virginia State Medical Association will appreciate the great benefit from this new journal, and will assist those in immediate charge in making it a power for good and a credit to the profession of West Virginia.

TASTES OF MOSQUITOES.

It has often been noted that mosquitoes seem to have special likes and dislikes and that some persons are much more annoyed by them than others. Now that the question of disease conveyance has become a more important consideration than the annoyance, the reasons for this special liking for individuals are being carefully studied by a number of observers. A summary of these observations and an account of a series of recent experiments have been made by Professor Galli-Valerio,[1] director of the Institute for Experimental Hygiene and Parasitology at the University of Lausanne in Switzerland. He has found that the color of the clothes worn by the individual has most to do with the supposed preferences of the mosquito. His experiments were conducted with various forms of anopheles. Nearly four times as many of these mosquitoes lighted on dark-colored clothes in a given time as on light colors. This shows that the chances of the number of mosquito bites may be greatly reduced by choosing light colors for clothing, though this is not sufficient to afford complete protection. It is thought that this is about as effective as tobacco smoke in securing immunity from the insect stings. This is so simple that as an additional precaution when in malarial countries it can be put into effect by all, and, as everything that helps to ward off malaria is of value, non-immunes going into malarial districts should be advised of it by their physicians. It is particularly the casual traveler in the tropics who is not likely to provide himself with the very light-colored clothing so commonly worn by the inhabitants, yet it is he who, most of all, needs the added protection against mosquito bites which is said to be thus afforded.

---

[1] Daily Consular and Trade Reports, Sept. 5, 1906, issued by the United States Dept. of Commerce and Labor.

THE CAUSE OF DEATH.

Physicians should appreciate the necessity of designating correctly the cause of death. Science is in no way served when the cause of death, for instance, is entered on the certificate simply as "convulsions," or "heart failure," or "pulmonary edema." The patient may have died immediately or directly in such circumstance, but these unqualified statements give no clue to the disease which was the essential, indirect or underlying cause. In later years relatives are often anxious when they themselves become ill; then, again, it will be found that questions of heredity in disease, very important to be settled, must forever remain obscure. From the legal viewpoint the matter is still more grave. A defective certificate may occasion the patient's family much vexation and at the same time give the authorities unnecessary work in the way of investigation. Occasionally there may be mortification for the physician not altogether undeserved. For example, to designate a death as due simply to meningitis, peritonitis or gastro-enteritis, without qualification, may not satisfy the coroner or medical examiner. The further statement will be necessary whether the disease was idiopathic or the result of a fall, a wound, a "criminal operation" or a poisoning. Here is an example of a death certificate correctly made out, which nevertheless became a "coroner's case:" "Asthenia de senectute; contributing cause, fracture at the neck of the femur." The fracture was probably sustained in falling out of bed or by slipping on the street, as is usual in such cases. But some one may have pushed or struck the deceased, becoming thus more or less responsible for the death. In any event, whenever an accident has contributed to a death, no matter how remotely, the case is one for investigation. In most communities a letter from a reputable and responsible physician to the authorities, accompanying such death certificates, will obviate official action and spare the family annoyance.

Medical News

ILLINOIS.

Chicago.

Committed to Dunning.—Dr. Christian R. Hartung was examined in the insane court September 6 and committed to the Cook County Hospital for the Insane, Dunning.

Hospital Dedicated.—St. Vincent's Hospital, Taylorville, was dedicated August 22 with appropriate ceremonies. The hospital was erected at a cost of about $25,000 and will be in charge of the Sisters of the Most Precious Blood.

Coroner's Record for August.—The coroner of Cook County reports for August a larger death roll than any month since the Iroquois Theater fire. The table of deaths from other than natural causes during the month was as follows: Suicide, 39; drowning, 29; heat prostration, 27; railroad accidents, 26; homicide, 14; street car accidents, 13; lightning, 1, and scenic railway accident, 1.

Warning Against Diphtheria.—The commissioner of health has issued a warning to parents and teachers of children of the public schools to pay particular attention to sore throats of children, no matter if they seem to be of minor character. The opening of the schools and the consequent exposure of more than 250,000 children to unsuspected cases of diphtheria are a most important factor in the increase of the disease.

Personal.—The king of Portugal has conferred on Dr. Alexander Hugh Ferguson a commandership in the Order of Christ of Portugal in recognition of his original work in surgery.——Dr. Clinton G. Lumley, who was operated on for appendicitis August 28, is making good progress toward recovery.——Dr. and Mrs. Bernard Fantus have returned from Europe.——Dr. Henry W. Cheney and wife have returned after an eight months' absence in Europe.

Tent Sanatorium Opened.—The tent sanatorium under the auspices of the Chicago Tuberculosis Institute was opened September 3, with three portable cottages, one of which is used for a dormitory, one for a dispensary and one for a kitchen. Ten of the 20 patients for which the sanatorium has accommodations at present were already on hand at the opening day, and several other applications are being considered. The initial outlay has been about $1,500 and it is expected that the expense to maintain each patient will be about $5 per week.

Mortality Report.—The mortality for the week ended September 8 was 515, or 46 less than for the preceding week, and 15 more than for the corresponding week of 1905. This is equivalent to an annual mortality rate of 13.10 per 1,000. Of children under one year of age, 127 died, and 83 over 60 years of age. Acute intestinal diseases led the death list with 113, followed by violence, including suicide, with 52; consumption with 49; heart disease with 49; Bright's disease with 47; pneumonia with 29, and cancer with 19. During the week 10 deaths from diphtheria and 10 from typhoid fever were reported.

INDIANA.

New Sanitarium.—Dr. John Little Morris is building a 75-room sanitarium and hospital at Columbus, with modern equipment, especially for the care of non-surgical, chronic diseases.

Typhoid Fever.—A great deal of typhoid fever is reported from Huntington County. The disease seems to affect chiefly the southern parts of Union and Rock Creek townships.——From Mitchell are reported 63 cases of typhoid, with 3 deaths.

Smallpox.—Reports to the secretary of the State Board of Health show the prevalence in a mild form of smallpox in Starke, Marshall, Fulton and Pulaski counties. During the last three weeks there have been more than 20 cases of the disease, all of a mild type.

Personal.—Dr. D. F. Davis, New Albany, has returned from Europe.——Dr. Edward N. Flynn has been elected mayor of Jeffersonville.——Dr. E. J. Schott, Terre Haute, was thrown from his carriage in a runaway acident and strained his back.——Dr. Chester C. Funk has been elected secretary of the New Albany board of health.

MARYLAND.

Baltimore.

Deaths from Violence.—During August 63 deaths from violence were reported, 11 of which were due to suicide.

Personal.—Dr. John W. Hawkins, Towson, has gone to Charles County, lower Maryland, for a visit.——Assistant Surgeon Benjamin H. Dorsey, U. S. N., is visiting his home at Ellicott City.

Vital Statistics.—During the week ended September 1, 145 deaths were reported. This is equivalent to an annual death rate per 1,000 of 13.05; for whites alone, 12.06, and for blacks alone, 18.32. Typhoid fever is on the increase.

State Society to Meet.—The semiannual meeting of the Medical and Chirurgical Faculty of Maryland will be held in the famous old Senate Chamber at Annapolis, where George Washington resigned his commission, on September 27 and 28. The address of welcome will be delivered by Governor Warfield.

New Hospitals.—The offer of the widow of Dr. Frank to give $75,000 to the Hebrew Hospital has been accepted. The building will be named "Doctor Samuel Leon Frank Memorial Hospital" and will be located on the grounds of the present institution. It will be the principal hospital and the present building will be used for incurables and nurses.——Dr. Harry

Adler has been elected to succeed the late Dr. Frank as president of the Hebrew Hospital and Asylum.——Dr. Frank G. Moyer will erect a sanitarium on the site of his present residence.

To and from Europe.—Dr. Hiram Woods, president of the Medical and Chirurgical Faculty of Maryland, and Dr. Robert Hoffmann have returned from Europe.——Dr. Roland B. Whitridge is spending September in Switzerland.——Dr. W. Hewson Baltzell is at Aix-les-Bains.——Dr. Lewis C. Lehr is at Schwalbach, Germany.——Dr. J. Hall Pleasants, who has been ill with typhoid fever in Europe, has returned to Baltimore.

MASSACHUSETTS.

Pay for Medical Examiners.—The board of health of Chicopee has voted to ask the Chicopee board of aldermen for $1,000 to defray the expenses of the proposed medical examination of school children and inspection of schools.

Physician Wins Suit.—Dr. Lyman A. Jones, North Adams, has won his suit against the city for $750, alleged to be due for extra work done during the smallpox epidemic of 1904, when Dr. Jones was physician of the board of health.

Personal.—Dr. Frederick G. Smith of Somerville has returned from Europe.——Dr. Frank L. Morse, for several years city bacteriologist, has been appointed city physician of Somerville to fill the vacancy caused by the death of Dr. Alvah B. Dearborn.

Typhoid Fever.—A serious epidemic of typhoid fever has developed at Lynn. During the last two weeks 24 cases were reported. The cases are not confined to any one portion of the city, but are scattered. It is feared that the water supply is polluted.——Springfield reports 18 cases of typhoid fever. They have developed within the last two weeks.——A number of cases are reported from Middle Farms.

New Nurses' Home.—The South Framingham Hospital and Training School has been given a new nurses' home by Messrs. Frank A. and Henry B. Day, West Newton, as a memorial to their parents. The hospital expects to secure the services of a woman physician as superintendent in place of Miss Annabel L. Stewart, who has been for nearly 12 years head of the institution and who has resigned, to take effect next month.

NEW YORK.

New York City.

St. John's Guild.—On account of the very heavy call for its services, the floating and seaside hospitals will remain open as long as funds are provided.

School for Cripples.—A school for cripples is to be built at a cost of $75,000. It will be five stories high, will have a roof garden and will be situated on Water Street.

Coney Island Hospitals.—Seaside Home, Brooklyn Children's Aid Society and the Health Home of the New York Children's Aid Society remain open. The Sea Breeze Home will be kept open until October 1.

Bellevue Doctors Robbed.—There are about 50 doctors at Bellevue Hospital and nearly all suffered from looting of their dormitories, which occurred September 4. The thieves made away with all accessible jewelry, clothing and money.

Infant Death Rate Higher.—There were 312 deaths among babies in the past week, against 233 for the corresponding week of last year, all dying of summer complaint. The infant mortality, as a rule, falls at this time of the year.

Home from Europe.—Dr. Warren S. Adams arrived from Liverpool on the *Oceanic*, September 6.—— Dr. J. Waldron Bartlett arrived from Europe on the *Caronia*, September 5.—— Dr. and Mrs. Hugh H. Young arrived on the *Oceanic*, September 5.

Child Scalded in Hospital.—On September 2 a child died from scalds received while taking a bath in the Randall's Island Hospital. Coroner Harburg, after a thorough investigation, found the occurrence due to neglect and carelessness on the part of the nurse who, in consequence, was discharged.

Patients at Pasteur Institute.—An unusually large number of patients have been admitted to this institution recently, and the arrival of six in one day has caused Dr. William L. Wheeler, director of the institute, strongly to urge the shooting of all dogs suspected of being mad. He suggests shooting them through the heart so that the brains may be available for examination.

Health Department Busy.—The rules of the board of education in regard to the admittance of pupils into the public schools make this a busy season for the board of health. Much of this work is the result of neglect on the part of physicians to report births. The force can dispose of about 600 such cases a day, and in addition, some 700 or 800 vaccinations are made daily.

Death Rate Among Tunnel Workers.—The officials of the Pennsylvania Railroad Company have issued a general statement to the effect that the lives and health of its workmen are not needlessly sacrificed in the construction of the tunnels under the East and North rivers. It has been stated that the death rate is no higher than obtains among men who build steel frame skyscrapers, and where accidents have occurred, they have been due, as a rule, to a disregard of the rules and precautions laid down by the company.

Buffalo.

Personal.—Dr. Eugene Smith has returned after a four months' trip abroad.——Dr. Alvin A. Hubbell is taking a trip on the Great Lakes.——Drs. Hubert U. Williams and F. Park Lewis and family have returned from abroad.

Medical Department to Open.—The Medical Department of the University of Buffalo will open for its sixty-first annual session September 24, and continue for 34 weeks. The opening address will be delivered by Dr. James E. King.

NEBRASKA.

Personal.—Dr. A. D. Wilkinson, secretary of the Nebraska State Medical Association, leaves on September 21 for a year's trip abroad. He expects to visit Japan, China, the Philippines and Siam and to return by the way of Europe. Dr. W. H. Orr, Lincoln, will act as secretary during Dr. Wilkinson's absence.

New President of State Association.—The Council of the Nebraska State Medical Association has elected Dr. F. A. Long of Madison to serve as president of the State Association in place of Dr. J. L. Green, who resigned to take the position as superintendent of the Illinois Eastern Hospital for the Insane, Kankakee, Ill.

PENNSYLVANIA.

Much Typhoid Fever.—According to the bureau of health of Pittsburg, typhoid fever is increasing in and around that city. Two thousand four hundred and ninety-one cases have been reported during the first six months of the year, as against 858 cases for the same period last year.——On account of the prevalence of typhoid fever at Hamburg, the opening of the public schools will be postponed until September 10. It has been discovered by the authorities that the infection was present in the drinking water. In 50 per cent. of the cases reported the water used came from a well found contaminated. One hundred cases are reported in the town.——In Phoenixville 40 cases have been reported in the past three months, many having resulted fatally. A state medical inspector detailed by Dr. Warren to investigate the sanitary condition of the town, reported things in an extremely bad condition, and the local board of health claims it is powerless in the matter of checking the disease without the coöperation of the town council. Dr. Dixon has notified the authorities to take immediate action to stamp out the disease.

Philadelphia.

Personal.—Dr. Thomas F. Neil has been appointed superintendent of the county insane asylum of Blair County, Pa.—— Dr. J. Malcolm Henry has returned home from a tour through Canada.

Hospital Report.—The report of the Medico-Chirurgical Hospital for August shows 5,489 patients treated; 1,510 of these were surgical. The accident ward received 913 cases. Electric treatment was administered to 196 persons and the *x*-ray was used on 168.

Improvements for Hospital.—Plans have been completed for the remodeling of the Willberham mansion, which was purchased for the purpose of increasing the facilities of the Frankford Hospital. The first and second floors of the building will contain two general wards, nurses' room and a diet kitchen. The third and fourth floors will be children's wards and private rooms. The building will be four stories high and will measure 114 by 62 feet.

War on Impure Candy.—The arrests of 19 retail candy dealers in this city by state dairy and food comissioner, Dr. Warren, resulted in the conviction of the men. The fine in each case was $57.50, making a total of $1,092.50. The fines were paid by the New York Glucose Company, known as the glucose trust. The successful crusade conducted by Dr. Warren against the manufacturers of impure candy is considered complete, and it is now stated that he will start a campaign against other impure food concerns in the state.

SOUTH CAROLINA.

Editorial Staff Named.—The editorial staff of the *Journal of the South Carolina Medical Association* is made up as follows Editor, Dr. J. Williamson Jervey, Greenville; associate editor, Dr. Walter Cheyne, Sumter, and managing editor, Dr. Curran B. Earle, Greenville.

State Society Meets.—At the annual meeting of the South Carolina Medical Association, Dr. T. Prioleau Whaley, Charleston. for 10 years its secretary, was elected president; Dr. Walter Cheyne, Sumter, was elected secretary, and Dr. Charles P. Aimar, Charleston, was re-elected treasurer.

College Changes.—Dr. Louis D. Barbot has been elected professor of anatomy in the Medical College of the State of South Carolina, vice Dr. Francis L. Parker, resigned.——Dr. Edward F. Parker has been elected dean of the Medical College of South Carolina, succeeding his father, Dr. Francis L. Parker, who has resigned.

New Hospitals.—The Hospital Association of Anderson County at its annual meeting announced that nearly $4,000 had been raised for a hospital. The site has been purchased and the work of actual construction is expected to be started soon.——The Florence Infirmary, established by Dr. F. H. McLeod and N. W. Hicks, has been opened to receive patients.

Resigns After Long Service.—After 41 years of devoted services to the Medical College of South Carolina, Charleston, Dr. Francis L. Parker has resigned as dean and professor of anatomy. The faculty and the board of trustees have adopted resolutions which set forth the splendid services done by Dr. Parker for his *alma mater*, and appropriate expressions of the appreciation they have for his services and their sincere regret at his resignation.

Scholarships.—The governor has announced the names of the following men to whom he has awarded scholarships in the Medical College of the State of South Carolina: First district, F. H. Marvin, Summerton; second district, L. S. Hay, Allendale; third district, F. M. Routh, Anderson; fourth district, W. T. Brockman, Greer; fifth district, B. L. Robertson, Lancaster; sixth district, J. K. Stealvey, Socastee, and seventh district, C. C. Owens, Columbia.

SOUTH DAKOTA.

First Conviction Under New Medical Law.—The first arrest under the new medical law has resulted in a conviction. A. H. Bruning, a "chiropractic," was arrested on complaint of the secretary of the State Board of Medical Examiners, on the charge of practicing medicine without a license. He was tried and found guilty, August 16. A nominal fine of $50 and costs was imposed and the case will be appealed, as it is desired to secure a final ruling.

Slaughter House Regulations.—The State Board of Health has sent out circulars to the county superintendents of health, requesting that they visit and inspect the slaughter houses in their respective counties and require the observation of the following regulations: 1. A plentiful and uncontaminated water supply. 2. Proper and adequate drainage for both the slaughter houses and premises. 3. A thorough cleansing of slaughter houses and premises from manures and offal after each butchering. 4. Each slaughter house should have water-tight floors, which should be washed after each butchering, ample subdrainage and clean, whitewashed or painted walls.

UTAH.

Fee Bill Adopted.—At the August meeting of the Utah County Medical Society, held in Provo, the medical fee bill was revised and adopted.

Personal.—Dr. Walter M. Stookey and family, Lehi, expect to sail for Europe, October 10.——Dr. Samuel C. Baldwin, Salt Lake City, returned August 28 after a five months' tour of Europe.

Health Commissioner Was Arrested.—Dr. M. R. Stuart, health commissioner of Salt Lake City, was arrested August 5 for creating a nuisance by causing garbage, swill, etc., to be dumped into Horseshoe Bend. He admitted the responsibility, but plead not guilty to dumping this garbage, and the case was tried. The jury disagreed.

Typhoid Fever.—Waterloo, just outside the city limits of Salt Lake, is reported to have a serious epidemic of typhoid fever. The county physician has been empowered to investigate the source of the infection of the typhoid cases, to have the milk supply of that section analyzed and the outbuildings inspected, and has ordered a general cleaning-up of that part of the city.

VIRGINIA.

Hospital Opening.—Abingdon Hospital was formally opened August 27, and the next day the patients were received.

Smallpox.—The board of health of Lancaster County has reported 18 cases of smallpox at Churchfield, near Irvington, and one case at Whitestone, only a few miles away. Quarantine has been established. The disease is mild in character and is confined to the colored population.

Personal.—Dr. Charles W. Rodgers, Staunton, while returning from a professional visit, had a narrow escape from drowning, saving himself and his horse, but losing his buggy.——Dr. A. Chambers Ray, Eagle Lake, has been appointed physician to the Randolph-Macon College, vice Dr. William S. Ellis, deceased.

WASHINGTON.

New Sanitarium.—The Northwestern Sanitarium Association, at Port Townsend, has been incorporated with a capital stock of $50,000.

Personal.—Dr. Grant Calhoun has been appointed health officer of Seattle, vice Dr. William L. Ludlow.——Dr. R. B. Cassil, Walla Walla, has returned from a trip to Alaska.

Will Yield to Decision of Experts.—The King County Medical Society, which made a strong protest against the attempt of the Chicago, Milwaukee & St. Paul Railway to extend i road through the Cedar River water-shed, has withdrawn it objection, on account of the opinion of sanitary experts that the watershed could be crossed without pollution to the water supply of the city.

WISCONSIN.

Leaves Large Estate.—The will of the late Dr. John A. Rice, Merton, has been filed for probate, the testator leaving about $100,000 in personal property and nothing in real estate.

Personal.—Dr. Henry W. Morgenroth, Berlin, who was operated on for appendicitis at St. Mary's Hospital, Oshkosh, August 14, is reported to be making an uneventful recovery.——Dr. Thomas S. Clark, Knowlton, has been committed to the State Hospital, Oshkosh.——Dr. O'Leary, Husher, sailed for Europe, August 30.

Physical Examination of School Children.—The Milwaukee Medical Society is making preparation for the inauguration of physical examination of school children. The expense of the experiment will be borne by the society, and Drs. Arthur J. Patek, Arthur W. Akerly and George P. Barth have been appointed a committee and placed in charge of the work.

GENERAL.

Hospital Cars.—It is reported that the Pennsylvania and the Baltimore & Ohio railroads are about to have hospital cars built to care for the injured in the railroad wrecks. The Erie is said to be the only eastern railroad at present possessing such cars.

Copies of The Journal Wanted.—We are in need of the issues of The Journal of July 7 and 14, 1906, so that orders for back numbers may be filled. If any of our readers will return these numbers we will remit ten cents for each copy, or will send in exchange any other numbers desired.

A Fraudulent Agent.—Dr. Franklin H. Martin, Chicago, asks us to warn physicians against one G. E. Simpson, who is fraudulently taking orders for *Surgery, Gynecology and Obstetrics.* He says that many physicians have already been victimized by this man by paying him in cash or giving him checks payable to his own order; and this notice is published in the interest of the profession and to stop his further operations.

Pathologists and Other Physicians Wanted in Illinois Hospitals.—The Illinois Civil Service Commission will hold examinations very soon for a pathologist at Kankakee ($2,500 a year and maintenance), and pathologists in six other hospitals for the insane, paying from $75 to $125 per month and maintenance; also for physicians in the charitable institutions, not insane, and for assistant physicians in the hospitals for the insane. These positions pay from $75 to $150 a month. There will also be examinations for surgeons in the Soldiers Orphans' Home at Quincy, positions which pay from $60 to $125 a month and maintenance. These positions are of great importance to the institutions of Illinois, and the commission is greatly interested in obtaining the very best talent for the examinations and in making them a success. Joseph C. Mason, secretary, Springfield, Ill., will send further information.

CANADA.

Winnipeg Hospital News.—The Winnipeg General Hospital treated 346 patients during the week ended September 1. Of this number 212 were men, 100 women ad 34 children.

Personal.—Dr. Charles Monod of Paris, France, is visiting his son, Dr. Ferdinand Monod of the Glengarry Hospital, Montreal.——Dr. Charles A. Ritchie, Winnipeg, Man., has gone to London, Edinburgh and Dublin to study.——Dr. Hamilton of Halifax is on her way to China to take a position in the hospital at Shanghai as a medical missionary.

Health Officers on Tour of Inspection.—Dr. Montizambert, director-general of public health, Ottawa, has been in British Columbia on a tour of inspection. Accompanied by the chief quarantine officer of British Columbia, Dr. Watt of the William Head quarantine station, he is visiting the Grosse Isle quarantine station and the leper hospital at Tracadie, N. B. They will return to British Columbia and choose a site for the new leper hospital in British Columbia.

Vaccination of School Children in Montreal.—No child is now allowed to attend school in Montreal unless able to show a certificate of successful vaccination. In certain new wards recently annexed to the city vaccination in the past few years has not been very rigidly enforced. In one of these out of a population of 600 pupils but 175 had been vaccinated. The Montreal medical health officer states, however, that there is now very little trouble in inducing parents to have their children vaccinated.

Analysis of Canned Meats.—A bulletin has just been issued from the laboratory of the Canadian inland revenue department dealing with the subject of canned meats. In all 322 samples were purchased in different sections of Canada and subjected to the same examination. Both canned meats from the United States and Canada were selected. The former were from dealers, but the latter were secured from dealers, wholesalers and also from the factories. Only four samples gave any evidence of decomposition, a proportion amounting to only 14 per cent. The preservatives sought for were salicylic, benzoic, sulphurous and boric acids, but the latter was the only one detected, and that in a percentage lower than required by the English parliamentary commission, namely, 0.5 per cent. A close inspection of the tabulated list of the analyses shows that as far as Chicago packing-houses were concerned in these products that two samples of one house showed "slight traces of boric acid" and "boric acid;" while two samples of another Chicago house showed "boric acid" and "meat badly decomposed."

FOREIGN.

Congress of Microbiology.—A three-day session of the newly founded Association for Microbiology—*Freie Vereinigung für Mikrobiologie*, was held at Berlin in June with a comparatively large and much interested attendance. The *Berliner* and the *Münchener med. Wochschr.* are publishing a simultaneous report of the proceedings. They represent the "last word" in bacteriologic, serotherapeutic and similar research among German scientists.

Retirement of Some Prominent German Professors.—It is rumored that von Leyden and Olshausen intend to retire from the medical faculty at Berlin University. E. v. Bergmann will also give up further teaching this fall when he passes his seventieth birthday, and W. Erb of Heidelberg will retire at the close of the winter semester. These men are all doing good work and do not feel their encroaching age, but they say they want to make room for the younger men.

To Combat Bovine Tuberculosis in Argentina.—The *Semana Medica* of Buenos Ayres states that the government has commissioned the director of the Bacteriologic Institute, don José Lignières, to go to Germany to study on the spot von Behring's method of treating tuberculosis in cattle. He is given leave of absence for five months, and the ministers from Argentina to France and Germany are ordered to facilitate his task, as special envoy from the government, by all the means in their power.

Demonstration Against Surgical Exhibition.—A foreign exchange states that an exhibition of Doyen's lantern slide, cinematographic representation of various operations, which he was giving, for some strange reason, before a lay audience, caused an uproar. The pictures representing an amputation of the arm and a trephining were accepted without protest by the general audience, but when Doyen proceeded to an abdominal operation the audience protested so clamorously against the reproduction that he was obliged to desist. Our exchange comments that such views are not adapted for the general public, however instructive they may be for medical men.

The Bottini Memorial.—A memorial tablet was recently unveiled at Pavia, Italy, to the memory of the late surgeon, E. Bottini. Behind the tablet were immured a gold medal with the portrait of the deceased and an elaborate souvenir volume containing works by his pupils and friends, with an address on parchment—all of which had been prepared to present to the master on the occasion of the twenty-fifth anniversary of his assuming the chair of surgery at Pavia. The plans for the ceremonies were annulled by the unexpected death of the great surgeon not long before the arrival of the anniversary. The tablet stands between one erected to the memory of Scarpa and another to Porta, and the inscription on the marble is merely a few words of tribute to the man "who by his genius in the science and the art renewed the glorious traditions of the Pavia school of surgery." Golgi is the dean of Pavia University, and Tansini is the present incumbent of the chair of surgery.

Visit of French Physicians to Germany.—A number of prominent French physicians and surgeons have recently taken a trip to Germany, with their ladies, and visited the scientific institutions in some of the larger cities. At Marburg, von Behring regaled the party with an account of his latest researches on tuberculosis, especially with a description of his tulase, a clear fluid containing somatic substance of the tubercle bacilli, obtained by treatment with chloral. It is used for active immunization or Mithridatization, as he calls it, and his extensive experience with sheep has been very encouraging. In the clinic it has to date been given subcutaneously, but it is given by the mouth to sheep, and this will probably prove the preferable route. Until the clinical value of this new Mithridatic remedy has been thoroughly established, he said, it will not be obtainable except in free samples for clinical research. Already favorable reports are being constantly received. He spoke rather discouragingly of the possibility of an effectual serotherapy for tuberculosis. Active immunization will probably be required, possibly combined with a serum. The trip generally proved so delightful and instructive, and the cordiality of the reception on the part of the physicians and surgeons of Berlin and elsewhere opened up such pleasant vistas of future trips of the kind, that, on Kutner's suggestion, an international committee for medical study trips was organized while the party was at Berlin. The committee appointed consists of Kossmann of Berlin as chairman, Bazot of Paris, Guyot of Geneva, Kutner of Berlin, Lifrange of Bertrix in Belgium, and Pini of Bologna.

LONDON LETTER.

(*From Our Regular Correspondent.*)

London, Aug. 24, 1906.

Typhoid Fever in India.

Lord Kitchener has presided over the first meeting of a committee on typhoid fever, which was held at Simla. He stated that he thought it necessary to form the standing committee to advise as to efforts to reduce typhoid fever among the troops and to coördinate in the work of the whole medical profession in this direction. The ravages of cholera were worse in days gone by, but they are now, happily, a reminiscence. He has great hopes that the scourge of typhoid fever will eventually be brought under control. Young soldiers are most subject to the disease on arriving in the country. For some time experiments in antityphoid inoculation have been performed in India and great advances have been made on the system prevailing at the time of the South African war. The thoughtlessness of the soldier with regard to care of himself is a great difficulty. If inoculation is to be made more popular, he thought efforts should be directed to make it less painful and unpleasant. He suggested an inquiry as to whether this could be accomplished by using a more diluted serum or distributing the dose over three or more injections, instead of two, as is the practice now, or reducing the amount of serum to be injected. Since the South African war the dose has been reduced considerably. If all discomfort could be avoided in the process an immune period of six months might be sufficient instead of two years, which is now aimed at. Then universal inoculation of the new arrivals might be looked for.

Phthisis in Calcutta.

In recent years the mortality from phthisis in the large towns of India has caused some anxiety to the authorities. In the absence of medical certification registration of the causes of death is imperfect, but such information as can be obtained points to a serious and increasing mortality from tuberculosis. In Calcutta, the matter has been specially investigated by the officers of the plague department. The results for 1905 have been published in a report to the municipality by Dr. F. T. Pearse. The population of Calcutta is 847,796—562,596 males and 285,200 females. The umber, of Hindus is 551,462—361,176 males and 190,286 females; and of Mohommedans 249,939—174,117 males and 75,822 females. The report takes cognizance only of those two classes which constitute about three-fourths of the population of the city. The number of deaths due to phthisis in 1905 was 1,648 or 1.9 per 1,000. In England the rate is 1.3; in Bombay, 3.8; and in Indian gaols, 2.96. Thus in Calcutta the rate is high as compared with European figures, but low as compared with Indian. The age and sex incidence of the mortality is peculiar. The death rate for males is 1.4 and for females, 2,86. For Hindus, 1.8 and Mohammedans, 2.8; for Hindu males, 1.4 and females, 2.4; for Mohammedan males, 1.6 and females, 4.6. The excess of mortality among females, especially Mohammedan females, is striking. In England, on the contrary, the death rate of males from consumption is higher than that of females. The proportion of cases at early ages is also higher in Calcutta than in England. The excess of female mortality is attributed by Dr. Pearse to deficiency of fresh air. He finds that the proportion of cases is higher in huts than in houses. The average number of persons to a room is 2.41 in former and 1.72 in the latter.

The Antitoxin Treatment of Diphtheria.

The above report also shows that since 1889 the mortality rate of diphtheria has declined from 40.5 per cent. to 8.3 per cent. in 1905, when it reached its' lowest point. How far this is due to the antitoxin treatment and how far to the more complete diagnosis of diphtheria by the aid of bacteriology may be debated. The declining mortality of tracheotomy cases, however, points to a marked influence of antitoxin. In the two years preceding the use of antitoxin the mortality was 66 and 70 per cent. respectively. In the next year, 1905, it was 50.2 per cent., and since then it has steadily declined to 27.6 per cent. in 1905.

The Proposed Union of the Medical Societies.

A meeting of the general committee of representatives of the medical societies in London has been held to consider the report of the organizing committee. Sir William Church presided. The first meeting of the members of the societies was held at the Royal College of Physicians, in 1905, for the purpose of promoting union. The report recommended that all male members of those societies which took part in the amalgamation should be permitted to join the new society on its formation as fellows or members without election, and that all female members of the societies should become members of the corresponding section or sections of the new society. It was recommended that the society should consist of the following sections which represented existing societies, but that the new society should have power to add new sections: 1, Anesthetic; 2, balneologic and climatologic; 3, clinical; 4, dermatologic; 5, diseases of children; 6, electrotherapeutic; 7, epidemiologic; 8, laryngologic; 9, life insurance; 10, medical; 11, neurologic; 12, obstetric and gynecologic; 13, odontologic; 14, ophthalmologic; 15, otologic; 16, pathologic; 17, surgical; 18, therapeutic. It is hoped that in the early future an anatomic and physiologic section and a section of preventive medicine will be formed. The Medico-Physiological Association and the Medico-Legal Society hope to join at some future date. It was recommended that each section should be self-governing so far as possible and should have direct representatives on the council of the society and on the editorial committee, but that expenditure should be subject to the control of the finance committee of the general council. The general management of the society would be under the control of a general council consisting of the president, the presidents of the various sections, two treasurers, two librarians, two secretaries, and 8 other fellows.

The Report of the Rotunda Hospital, Dublin.

The reports of this celebrated hospital are always looked forward to with interest by those interested in the progress of obstetrics. In the report for 1904-5, which has recently been issued, important structural additions are announced which will increase the accommodation by two large maternity wards and will supply ample isolation wards, a special room for the delivery of infective patients, and a disinfecting chamber. The maternity beds are of an antiquated pattern and date from a time when it was not uncommon to place two mothers with their babies in one bed. Their width precludes the possibility of placing cots between them and as a result the child has to be placed in bed with its mother. Many disadvantages follow: The infants are irregularly fed and occasionally suffer from infective enteritis, the result of the mother's dirty fingers or her pocket handkerchief being placed in the child's mouth. A more serious result is fatal overlying. A new form of bed has been introduced with a lever and rachet arrangement for elevating the head so as to ensure more efficient lochial drainage. The number of women delivered in the hospital has been steadily increasing and during the year exceeded that of any similar period since the foundation of the hospital. The number of admissions was 2,241 and of deliveries 1,904. As the result of better antisepsis and the more even distribution of the admissions, which prevented the overcrowding recorded in the last report. the morbidity has fallen from 10.7 to 6.7 per cent. and the number of deaths from 13 to 6. A most useful form of chart is employed for more readily recording morbidity and has been adopted by many other maternities. It consists of separate charts for temperature and pulse and is ruled with a deep line at 99° on the former and at 90° on the latter. Temperature and pulse must rise above these lines and remain above them for 3 consecutive morning and evening registrations, or in other words, for a period of 24 hours, before the case is recorded in the books as morbid. Thus the transitory and unimportant exacerbations of temperature and pulse which are not infrequently seen in cases which it would be misleading to term morbid. are eliminated. Furthermore, the irregularities of pulse and temperature so frequently seen within 24 hours of delivery are not taken into account.

Doctors and Medical Emergencies.

The refusal of a physician to respond to an emergency call by persons who are not his patients often becomes a subject for criticism in coroners' courts. The following case is an example: A man poisoned himself by drinking oxalic acid. A physician who was summoned refused to go on the ground that the man was not his patient. The coroner, in summing up the evidence, raised the question as to whether the death of the diseased was accelerated by the absence of medical treatment and, if so, whether any one was to blame. He said that it is very difficult to say whether medical assistance would have been of any use or not. The opinion of the police surgeon was that it would not. The jury, however, could not overlook the fact that the first physician called, though told that the man had poisoned himself, refused to go on the ground that the deceased was not his patient. He was asked by the coroner whether he would like to attend the inquest or had any statement to make. He replied that he was not aware that he was bound to attend to any call that might be made on him, whether by the police or other persons. If the police required assistance they had their proper officer to whom to apply. In the present case he was expecting to be called out and therefore declined to leave home. Commenting on this, the coroner said that there is no law which compels a physician to answer a call to a man dying in the next street. But he said that he thinks there is a law higher and stronger than the law of man which calls us to try to help those in great distress without waiting to think what it will cost us, or what we shall have to pay, or whether it is convenient. Even those who have no medical knowledge would feel it a duty to go and help, as one witness did, if they knew a man was dying. He thought that the refusal of the physician to go in this case brought disgrace on a high and honorable profession. The jury endorsed the coroner's remarks by adding them as a rider to the verdict. Subsequently, the proceedings at the inquest were considered by the North-East Essex Division of the British Medical Association and a protest was made against the coroner's remarks. The meeting resolved that it is not the duty of individual members of the profession but of the municipality to make proper provision that so far as practicable no case of sudden and dangerous illness shall remain without prompt medical attention; that while physicians are ever ready to respond to the calls of humanity they are bound to consider the claims of their own patients and can not neglect these to attend to casual calls to strangers; that such summonses, even when stated to be urgent, are often found to be not so; that in the present case the messenger had not made clear to the physician the urgency of the case; that the members of the division, while repudiating the impracticable view of their duties in such cases suggested by the coroner, would be prepared to coöperate with the municipal authorities in devising a proper scheme for providing medical attendance in emergencies.

The Ventilation of the House of Commons.

The ventilation of the House of Commons has been a frequent subject of debate during the past 40 years and no satisfactory method has ever been devised. The ventilation of both houses of Parliament was originally planned by Dr. Boswell Reid. From 1865 to 1889 it was superintended by Dr. John Percy, the metallurgist, who devised many ingenious contrivances for cleansing the entering air and for regulating its flow; but he never succeeded in establishing a system beyond the reach of criticism or one equally adapted to the variations of weather. Since his death, the problem has continued and the chemical examinations of the earlier period have been supplemented by bacteriologic ones. Last year a committee consisting of Sir Michael Foster, as chairman, with Dr. J. S. Haldane and Dr. Mervyn Gordon, was appointed to carry out further systematic observations. Their report has been recently published. Whether judged by the amount of carbonic acid present, the temperature or the humidity, the atmosphere of the House was found to fulfill all reasonable requirements. The cause of the appointment of the committee was an outbreak of influenza among the members. It was admitted that so far as objective tests went, the quality of the air of the house was good, but the subjective test of the members' sensations pointed in the opposite direction. It was a common experience that the air of the chamber wanted "freshness," and that a stay in it for a length of time caused "lassitude and a feeling of heaviness." It was also pointed out that as the air is admitted through the floor it is liable to dust and various pollutions carried on members' boots. The character of the air admitted from the terrace was also impugned. It was found that, although the Thames mud below the terrace swarms with intestinal bacteria, these but seldom reach the inlet, either in the form of spray or dust. The admitted air is washed and filtered through cotton wool. Even before washing it presents no appreciable quantity of any noxious ingredient. The boots of the members were found to be responsible for a small quantity of dried and powdered manure in the dust of the house. There was no discoverable entrance of influenza by either road. Dr. Mervyn Gordon has devised an ingenious method of testing the contamination of the air of rooms by speakers. He discovered that a characteristic bacterium (*Streptococcus brevis*) is always present in human saliva. On placing plates of agar in various positions about a room cultures of this organism appeared. He demonstrated the fact that in speaking droplets of saliva are projected through the air to a distance varying with the vigor of the speaker, sometimes as far as 40 feet. He inoculated the mouth of a speaker with an emulsion of a harmless and easily recognized bacillus (*B. prodigiosus*) and distributed plates in various position in the House of Commons. On one plate, which was placed on the minister's box, he found no fewer than 83 colonies of this bacillus. There was abundant evidence that a member convalescent from influenza might be a source of danger to those in the direction of his speech. The committee recommend a more abundant introduction of air and its better diffusion. As regards the introduction of dirt into the house on the feet, ample precautions are already taken against ill results. The matting on the gangways is disinfected weekly and the floors are aspirated with a vacuum cleaner. The amount of dust so extracted from the debating chamber amounts to 45 pounds weekly.

VIENNA LETTER.

(*From Our Regular Correspondent.*)

Vienna, Aug. 12, 1906.

New Regulations for the Out-Patient Departments in State Hospitals.

With the beginning of the new term or semester at the university hospital, new regulations for the admission of patients to the out-patient halls will come in force for all public, i. e., state hospitals in the capital. The abuse has attained such a degree that at last our ever too slow magistrates were forced by a very powerful agent to condescend to reconsider the matter. This most influential agent was the deficit in the yearly report of the financial committee, which reached the figure of 27 per cent. of the total turn-over for 1904-5. A joint action of both the hospital managers' board and the representative of the medical council was proposed and resulted in the adoption of the long-expected changes. In future, material help to these out-patient departments will be free only to such as will provide a testimonial of poverty, to be signed either by the landlord of the tenement or by specially appointed guardians of the poor. This testimonial will admit the bearer to the out-patient department or ambulatorium, as it is termed here, and he will receive in exchange for this document a card entitling him to be seen by the medical staff of the hospital. For certain cases exceptions to the rule are provided for. Thus every case of accident or emergency is free from all formality or "red tape." If the treatment has to be continued for a very long period, or by unusual apparatus and remedies not in possession, as a rule, of the general practitioner (radium, *x*-rays), the patient or his medical advisers may apply for permission to frequent the ambulatorium. A moderate charge is then not inappropriate. Patients of the hospital wards, if discharged, may continue the treatment if it proves necessary, at the ambulatorium without any special permit. This applies to the surgical and certain medical cases. A special feature, and one which will meet the approval of all general practitioners, is the clause debarring persons belonging to one of the obligatory sick benefit clubs from the privileges of the hospital. These persons, who by their positions as subordinates of commercial or business establishments are by law forced to enter one of the "contract clubs," and who have to be attended by specially appointed contract doctors, have their own specialists and still abuse the hospitals. They will have to be seen in future by their own medical advisers. Furthermore, the present habit of supplying the out-patient with bandages, medicines and the like free of charge will be stopped, only such material as is used in the dressing room for surgical patients will in future be granted. To insure a just mode of dealing with the patients they will be treated according to the time of their arrival.

Increase of Poisonous Serpents and Protective Measures.

Certain districts in the southern countries of Austria are suffering from the presence of dangerous serpents of the viper type. The abnormal condition of the temperature seems to have a very favorable effect on the development of whole families of these pests, and during recent maneuvers several accidents happened therefrom. The ministry of war, therefore, has ordered a number of men in each company to be supplied with small packets of permanganate of potassium, which has been found to be very useful in counteracting the poisonous effects of the bite, and small gratuitous quantities of the permanganate are distributed in the affected district by the local authorities, apart from the regular "serpent hunts" established by certain army officers.

New Radioactive Baths.

Ever since the examinations, conducted by competent scientists, of the nature of the therapeutic action exercised by the Gastein waters have shown that the main source of the beneficent quality is the presence of radium emanation, experiments have been going on in the place where the greatest quantities of pitchblend and radium salts are found, in Joachimsthal near Prague, to ascertain whether the waters found in these mines could not be used for medical purposes. At the clinic of Professor Neusser of Vienna, whose name is well known in Europe, a large number of patients have been subjected to a treatment with these waters. Patients with gout, rheumatism, neuritis and diabetes have been benefited by the internal and external use of Joachimsthal mine water. It has been found that there are two distinct groups of waters to be obtained therefrom. The weaker water, containing from 8.000 to 10,000 volts of emanation, was derived from the underground springs and brooks, which are constantly flowing in the deeper shafts and have to be pumped away to keep the mine workable. The stronger water was obtained from the refuse of the mining process, which combines various chemical processes, and in its last step requires the washing of the material by sulphuric acid. The ultimate results are uranium (used for coloring purposes) and a water charged with radium emanation in a high degree, so that it excels the Gastein waters three or four times in its voltage. These latter waters have been used also for prostatic enlargement with remarkable success. The baths have shown themselves so active that general symptoms (due to destruction of leucocytes) may appear after incautious use. In Joachimsthal itself, a bathing house with at present only 12 cabins has been established for radium baths. In a similar way the hot sulphur baths of Baden, near Vienna, have been tested and the presence of radium emanation, though in a lower degree, was detected. The experiments tend to show that the presence of the active principle is in an inverse ratio to the temperature of the water. The sulphur mud deposited at the hot springs in this place contains radium bromid, so that it affects the photographic plate. This explains why, for instance, inveterate cases of skin disease respond so readily to the mud baths at Baden, although they are refractory to water baths and ointment even in Achen or other hot sulphur baths. It is planned now to institute special radioactive sulphur baths in this place, and it will be the first health resort of its kind which can boast both of the vicinity of the capital and of the radioactivity.

Pharmacology

SOMNOS.

To the Council on Pharmacy and Chemistry of the American Medical Association:—Your subcommittee, to whom was assigned Somnos, H. K. Mulford Company, submits the following report of experiments, undertaken to compare the effects of Somnos with those of chloral hydrate. These experiments demonstrate that the statements made in regard to the action of Somnos are in conflict with Rule 6 of the Council, which requires: "No article will be admitted or retained concerning which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to the therapeutic value." It is, therefore, recommended that Somnos be not approved for inclusion in the book until the claims made for it are corrected. It is also recommended that the report be published:

The Pharmacology of Somnos.

When these experiments were begun, April, 1906, there was nothing in the advertising literature on Somnos to indicate whether this article is a solution or a pure substance. On the label on the bottle, in the circular accompanying the bottle, and in the booklet "Somnos," the word Somnos seemed to be used as a synonym of "Chorethanal alcoholate," $C_9H_{11}O_5Cl_9$ and physicians were prescribing and pharmacists dispensing it in the belief that it was a pure substance. "The pure substance; some kind of an alcohol; nothing to do with chloral," was the way the druggist from whom the samples were purchased put it. Thus information absolutely indispensable for any rational comparison of Somnos with other hypnotics was witheld from the physician.[1]

Hence, before beginning the physiologic experiments it was necessary to determine the strength of the preparation; for this purpose three chlorin determinations (by the Carius method) were made. On the assumption that all the chlorin present was in combination as chloral glycerate, $C_3H_5[CCl_3.C(OH)_2]_3 = C_9H_{11}O_6Cl_9$, and calculating the percentage of this in Somnos, the following results were obtained: (1) 5.11 per cent.; (2) 5.15 per cent.; (3) 5.10 per cent.

Somnos, therefore, was found to contain approximately 5 per cent. of chloral glycerate and its physiologic action was compared with that of a 5 per cent. solution of hydrated chloral. In some experiments the hydrated chloral was dissolved in water; in others, in 10 per cent. alcohol (Somnos was found to contain at this time about this percentage of alcohol); in other experiments glycerin was added, as Somnos was found to contain this substance. No very marked differences were found in the physiologic action of the three solutions.

FATAL DOSE OF SOMNOS FOR THE LOWER ANIMALS.

The booklet on Somnos states that "Somnos has no toxicology"; that while chloral hydrate causes "acute poisoning," "deep coma," etc., Somnos is "harmless in twenty times the dose prescribed," "coma unknown, etc." The physician would scarcely suspect from such statements that Somnos is as poisonous a substance as solutions containing hydrated chloral in corresponding amount; that such is the case is shown by the following experiments. These experiments were necessarily made on the lower animals. While such results do not enable us to draw very definite conclusions as to the absolute toxicity of poison for man, the results on animals are conclusive as regards the relative toxicity for man of such closely related drugs as hydrated chloral and Somnos.

EXPERIMENTS ON MICE.

Injected subcutaneously into mice, there is but little difference in the lethal doses of Somnos and a 5 per cent. solution of hydrated chloral (Tables 1 and 2).

Table 1.—Somnos injected subcutaneously.

Weight of mouse	Somnos c. c.	$C_9H_{11}O_6Cl_9$		Results
		Per mouse	P'r gm. mouse	
19.86 gm.	0.28	13.9 mg.	0.7 mg.	Survived.
18.12 gm.	0.25	12.68 mg.	0.7 mg.	Survived.
19.35 gm.	0.29	14.51 mg.	0.75 mg.	Died 1¾ h.
18.62 gm.	0.3	14.9 mg.	0.8 mg.	Died 15 h
15.68 gm.	0.26	13.33 mg.	0.85 mg.	Died 4 h.

EXPERIMENTS ON GUINEA-PIGS.

Administered *per os* to guinea-pigs, there is but little difference in the lethal dose of Somnos and a 5 per cent. solution of hydrated chloral in water or dilute alcohol (Tables 3, 4 and 5).

On page 5 of the booklet "Somnos," the astonishing statement is made, "All tests showed that Somnos, given in twice the fatal dose of chloral hydrate, merely produced natural sleep. from which the animals awakened in a normal condition." Since Somnos is about a 5 per cent. solution of chloral glycerate, it is evident that a 5 per cent. solution is here compared with a pure substance: this is equivalent to saying that it is possible to give more of a 5 per cent. solution of a poison than of the undiluted poison. When it is remembered that in the booklet in which this statement is made the strength of

---

[1] Two weeks ago (Journal A. M. A., Sept. 1, 1906, p. 695) it was pointed out that the manufacturers now give this information, but in a wholly unnecessarily obscure form.

Somnos is nowhere *given*, can there be clearer evidence of a deliberate attempt at misrepresentation?

2. The conclusions drawn by C. C. Stewart in a report in Bulletin, No. 1 of the American Pharmacologic Society are of interest in this connection. This writer *states*, p. 19: "As nearly, therefore, as can be determined by experiments on the lower animals, twenty times the normal dose (that is, 10 ounces of the elixir, Somnos, for a 70 kilo. man) must be considered as an extremely dangerous quantity, while thirty times the prescribed dose (that is, 15 ounces for a 70 kilo. man), may be *considered* as lethal." It is a well established fact in pharmacology that the more highly developed the brain the more toxic, relatively, are substances which act primarily on this organ; hydrated chloral, for example, is, in proportion to body weight, more toxic for man than for the dog. Hence it is fair to assume that this figure 20, derived *from* experiments on the lower animals, is high rather than low. Yet the firm has been sending broadcast throughout the country the statement that Somnos is "harmless in twenty times the dose prescribed." To what extent this statement has been accepted it is impossible to state. In the booklet, "Somnos," p. 17, is an interesting *testimonial* from Kent Kibbie, professor of anatomy, Medical Department, Dallas University, Fort Worth, Texas: A woman violently insane for three weeks, to whom had been given "liberally" "morphin, chloral, sulphonal, and the bromids," was given ten tablespoonfuls of Somnos in the course of five hours; after five hours, she "*simmered* down" and slept for twelve hours. The question may be asked what would have been the result had she received twenty to forty tablespoonfuls, the amount which is stated by the manufacturer to be harmless?

It may be noted, in this connection, that in the above report Stewart records no experiments on *the comparative toxicity* of Somnos and hydrated chloral; if the American Pharmacologic Society is really endeavoring to get impartial information about Somnos before the medical profession, it would seem that this should have been one of the first subjects investigated.

EFFECTS OF SOMNOS ON RESPIRATION, CIRCULATION AND TEMPERATURE.

The booklet on "Somnos," in comparing the effects of *Somnos* with *chloral* hydrate states, page 13, *for* Somnos, "heart never depressed; pulse strong, regular and full, respiratory center stimulated rather than enfeebled, temperature uninfluenced," etc., while the dire effects of hydrated chloral are stated thus: "Weak, irregular, slow, feeble pulse; diminished respiration and lividity; temperature subnormal," etc. In the following experiments, the effects of Somnos on respiration, blood pressure and temperature were compared with those of corresponding amounts of hydrated chloral; the doses employed were just sufficient to cause a few hours quiet sleep. Sometimes the sleep caused by Somnos was slightly deeper and more prolonged; in other cases, the effect of the hydrated chloral was slightly greater, but we do not believe that the most experienced observer could have told from the effects with which drug he was working.

Experiments on Dogs.—Experiments were made on two dogs very similar in breed and disposition:

Experiment 1.—April 30, 1906. Black bitch; weight, 4.75 kilos.

10:26 a. m.—Rectal temperature, 39.6 C. Very lively; barking.
10:28—1.899 gm. hydrated chloral dissolved in 38 c.c. of 10 per cent. ethyl alcohol *per os* (=0.4 gm. hydrated chloral per kilo. body-weight).
10:32—A little quieter, but moving about; staggering. Stands on
10:37—Rolling about; raises body up on fore feet.
10:36—Unable to stand: tries it and falls.
hind legs; does not bark.
10:35—Tumbles about a little.
10:38—Respirations 44 a minute.
10:39—Barely able to raise head; does not react strongly to pinching ear.
10:40—No conjunctival reflex.
10:43—Impossible to arouse.
10:45—Respirations 68 a minute.
11:15—Rectal temperature 38 C. Respirations 36 a minute. No reflexes.
12:00—Moved about on insertion of thermometer; had to be held. Rectal temperature, 35.9 C. Easily aroused, almost gets up.
12:45—Moves about; can raise up on forelegs; then falls. Very "groggy." Impossible to insert thermometer without holding.
1:00—Rectal temperature, 35.8 C.
1:20—Slight convulsive movements.
2:00—Dog standing, but staggering. Rectal temperature, 36.7 C. Up and howling.
3:00—Practically recovered; very noisy. Rectal temperature, 38.4 C.
4:00—Rectal temperature, 38.8 C. Entirely recovered.

Experiment 2.—May 1, 1906. Black bitch; weight, 3.943 kilos.

11:06—Rectal temperature, 39.6 C.
11:10—31.5 c.c. Somnos given *per os* (=1.577 gm. of chlorethanal alcoholate = 0.04 gm. per kilo.).
11:15—Movements slightly incoördinated.
11:19—Tumbling about; hind legs paralyzed, but holds head up.
11:21—Barely holds head up.
11:26—Lying down, unable to hold head up; 40 respirations a minute.
11:35—Moves head slightly on inserting thermometer.
11:40—Rectal temperature, 37.8 C. Reacts very slightly to pinching.
11:45—Respirations, 42 a minute.
11:50—Conjunctival reflex absent. Impossible to arouse; pinching, etc., causes slightly accelerated respiration.
12:05—Barely perceptible reaction on insertion of thermometer.
12:10—Rectal temperature, 36.2 C.
12:45—No reaction on insertion of thermometer.
12:50—Rectal temperature, 34.8 C.
1:05—Respirations, 18 a minute.
1:15—Shows tendency to wake; throws herself about slightly.
1:20—Rectal temperature, 34.3 C.
1:25—Almost gets up. Respirations, 16 a minute..
1:50—Rectal temperature, 34.2 C.
2:00—Respirations, 16 a minute. Deeply under; can be aroused slightly.
2:10—Quivering.
2:30—Reacts considerably to insertion of thermometer.
2:35—Rectal temperature, 34.4 C.
2:39—Holding head up; tumbles about a little.
2:55—Sitting up, but very unsteady.
3:00—Stood up, but very unsteady.
3:05—Rectal temperature 36.2 C.
3:20—Up and walking about; almost recovered.
3:35—Rectal temperature 37.2 C.
4:20—Rectal temperature 38 C.

The condition of the animals in these two experiments was very nearly the same; the narcosis was equally prolonged (about three hous). The narcosis from Somnos was a little deeper; the temperature and respiration were also more depressed. The effects on the temperature are shown in Figures 1 and 2.

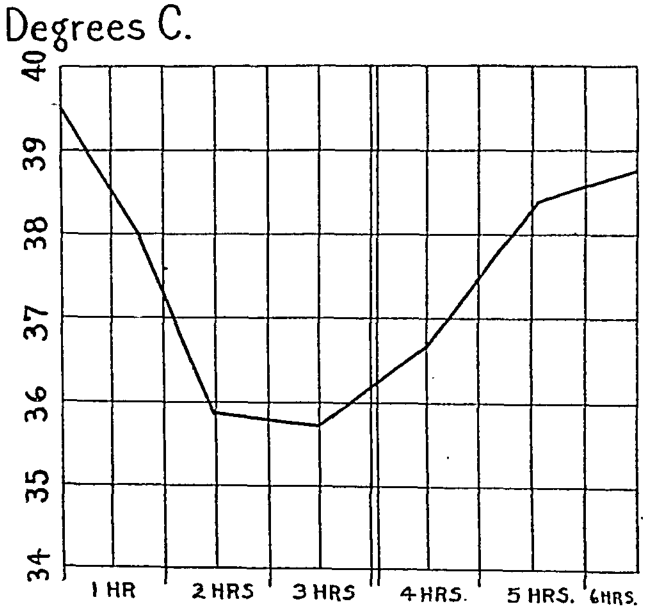

Fig. 1.—Experiment on a dog (1) showing depression of the temperature caused by 38 c.c. of a 5 per cent. solution of hydrated chloral (= 0.4 gm. hydrated chloral per kilo. dog). This solution, which about corresponds in strength to Somnos, caused less depression of the temperature than did the latter (cf. Fig. 2). The sleep continued about three hours.

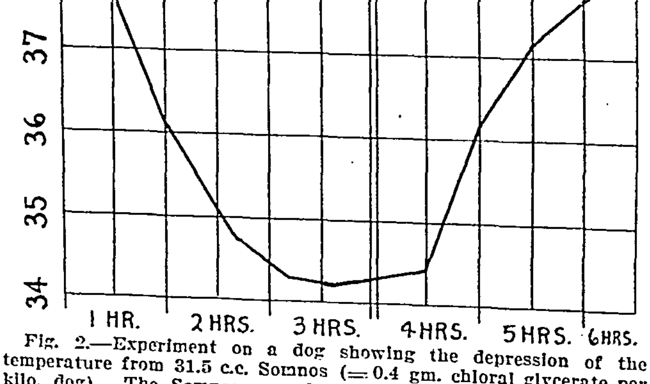

Fig. 2.—Experiment on a dog showing the depression of the temperature from 31.5 c.c. Somnos (= 0.4 gm. chloral glycerate per kilo. dog). The Somnos caused a greater depression of the temperature than did a solution of hydrated chloral of corresponding strength (cf. Fig. 1). Sleep continued about three hours.

In the following experiment a smaller dose of Somnos was given; the results show the inefficiency of small doses:

Experiment 3.—May 2, 1906. Yellow bitch, 5.98 kilos.
11 :00 a. m.—23.9 c.c. Somnos (containing 1.196 gm. chlorethanal alcoholate or 0.2 gm. per kilo.) given *per os.*
11 :25—Lying down, asleep most of the time; very easily aroused; gets up and seems normal, except for some incoördination. After a little the incoördination passed off, but she continued sleepy for about three hours; was easily aroused by snapping fingers.

Blood Pressure Experiments.—The following blood pressure experiments were made:

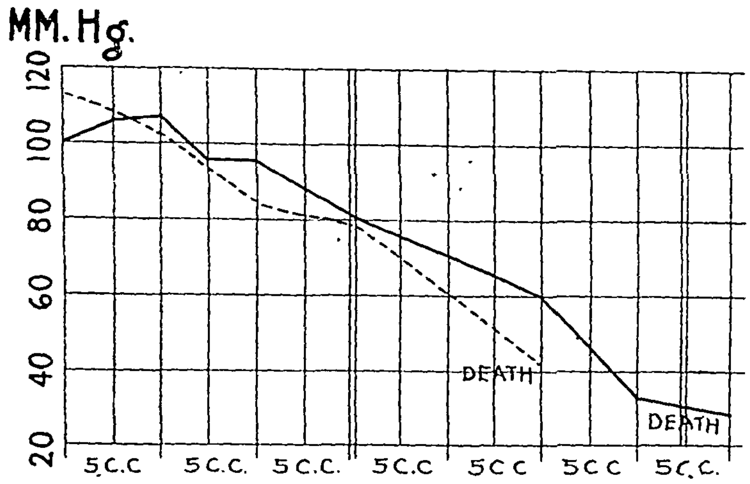

Fig. 3.—Showing the depression of the blood pressure from equal amounts of Somnos (dotted line) and a 5 per cent. solution of hydrated chloral (continuous line). The effect on the blood pressure was about the same, but death resulted from a smaller amount of Somnos than from a 5 per cent. solution of hydrated chloral. The figures on the left represent blood pressure in millimeters of mercury.

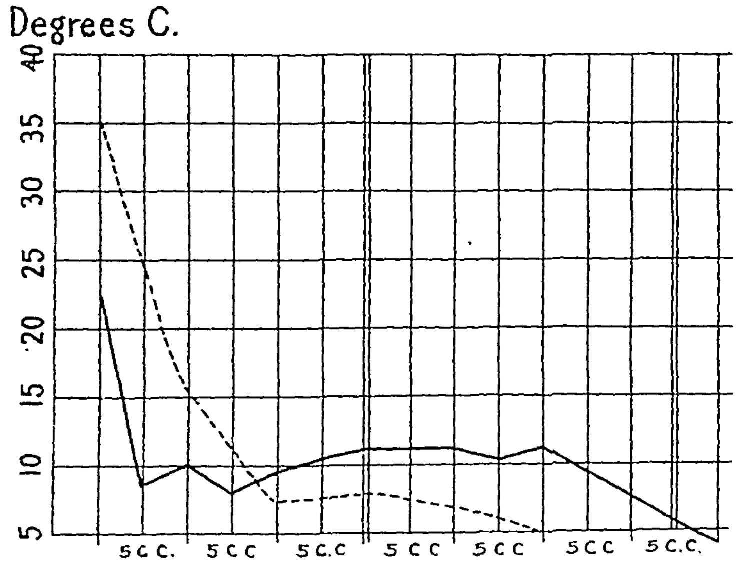

Fig. 4.—Showing the effect on the respiration of equal amounts of Somnos (dotted line) and a 5 per cent. solution of hydrated chloral (continuous line). The depression is about as great from the one as from the other.

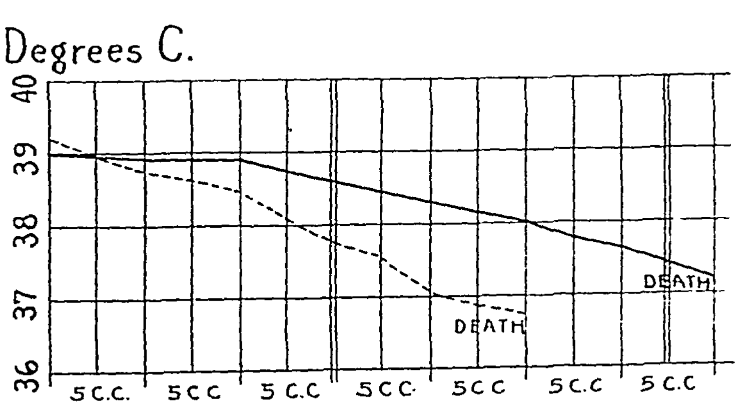

Fig. 5.—Showing the depression of the temperature from Somnos (dotted line) and hydrated chloral (continuous line). Somnos caused a greater fall of temperature than did an equal amount of hydrated chloral.

Experiment 1.—April 25, 1906. Rabbit, 2190 gm. Somnos injections into saphenous vein.

3 :26	....	....	6	29	....
3 :38	....	....	4½	....	....
3 :40*	....	....	....	....	37.2

*3 :40, respiration ceased; 3 :42, heart ceased.

Results of these experiments are shown in Figures 3, 4 and 5. Many other similar experiments were performed. The results were very uniform and admit of the following conclusions: Somnos is slightly more toxic than a 5 per cent. solution of hydrated chloral in water; the narcosis produced by it is slightly deeper but the respiration and temperature are also correspondingly more depressed; the blood pressure was equally depressed. The physiologic action of Somnos is practically indistinguishable from that of a 5 per cent. solution of hydrated chloral in 10 per cent. alcohol; sometimes the one, sometimes the other produced a slightly greater effect (depending probably on individual variations in the animals) but witn the deeper narcosis there was invariably associated a greater depression of the respiratory center and of the temperature.

The urine of rabbits which had been given Somnos contained a levo-rotatory compound which reduced Fehling's solution readily; it was probably urochloralic acid, the same substance found in the urine after the administration of hydrated chloral.

Experiments on the effect of Somnos on the number of red blood corpuscles (on which the manufacturers lay considerable stress) have not yet been made; but surely no one experienced in blood work would attach much importance to experiments such as those described in the booklet on "Somnos," pages 6 to 10.[3] The method of administering the drug, the time at which the blood was taken for examination, the intervals between the different experiments are passed over without a word. It is very improbable that amounts of hydrated chloral varying from 1½ to 2 grains, amounts having no noticeable effect on a dog, would cause a reduction of 16 02 per cent in the number of red blood corpuscles.

---

[3] These statements are repeated, practically unchanged, in the report by W. H. Lippert, M.D., in Bulletin No. 1 of the American Pharmacologic Society.

In the absence of any proof, the statement on page 4 of the booklet "Somnos," that Somnos produces sleep by causing a contraction of the neurons and that it is the only hypnotic known possessing this property, is an insult to the intelligence of the physician

CONCLUSIONS.

To sum up our results on the physiologic action of Somnos: We have been completely unable to verify the claims of the manufacturers that Somnos is less toxic than hydrated chloral, or that it has a less depressing effect on temperature, respiration or circulation. On the contrary, the physiologic effects are indistinguishable from those of hydrated chloral, doubtless because the action of Somnos is simply the action of hydrated chloral. We can see nothing in the animal experiments or in the chemical composition which would suggest that Somnos would possess therapeutic advantages over an elixir of hydrated chloral of corresponding strength.[4]

It is to be hoped that physicians who have been blindly using Somnos without even knowing the strength of the preparation, much less what it is, will compare its effects with those of a 5 per cent. elixir of hydrated chloral[4]

The Vice of Generalizing.

According to Rupert Hughes, writing in the current *Harper's Weekly*, says a lay exchange, the habit of generalizing from single sentences is far too general and influential One would think, from some of the generalizations, he says, that the monopolists of money, for example, had also monopolized wickedness "Yet the news of the day will tell of preachers caught in plagiarism or adultery, of druggists selling poisoned soda water, of bakers vending unclean bread, of theological students cheating" Each trade, he says, has its graft The fact is that "drawing indictments against classes is as insane and illogical as drawing indictments against nations" There are "burglars who are chaste, and parsons who are sots there are rich women who are nuns of asceticism, and poor women who are so vilely extravagant as to bankrupt their ditch-digging keepers; there are poets who are domestic models, and plumbers who are voluptuaries; there are rich men who overwork, and poor men lazy enough to beg; there are millionaires' sons who are normal and athletic, and self-made men who are degenerates; there are robust athletes who are abnormal, and cigarette fiends who are leaders of progress; there are Sicilians who never saw a dagger and Puritans who seek vendetta with a knife or with poison; there are policemen who would reject a bribe, and senators who are devoted to their country; there are chorus girls of unimpeached repute, and Sunday-school teachers who commit infanticide."

The above is interesting to physicians, in so far as the comparison would apply with equal force to medicinal agents, whether official or proprietary. In the crusade against nostrums, some are inclined to go to the extreme. All nostrums are proprietary medicines, but by no means are all proprietaries nostrums. Just as the laborer is worthy of his hire, a fair reward should be allotted to the discoverer of a medicinal agent; but this reward should not be made perpetual. A coined word, trademarked, grants a perpetual monopoly, and hence should not be encouraged. But a patented article, or a patented process of manufacture gives protection for a limited time only, and is not necessarily to be condemned.

In a recent letter in The Journal, the following appeared in parenthesis: "I regret to say that this is also a proprietary remedy, but it seems to work well; possibly other silver compounds would do as well." Our correspondent evidently did not know that the preparations he had previously referred to in his communication are also proprietary. Universal condemnation of proprietary preparations will not help the work of ridding the medical profession of nostrums. We, therefore, appeal to our readers to use judgment, tempered with patience, in dealing with this troublesome question

Correspondence

The Walker Resolutions.

Kansas City, Sept. 6, 1906

To the Editor:—After reading Dr. Carstens' letter in The Journal, September 1, I desire, as the mover of the motion to lay the Walker resolutions on the table, to correct some erroneous impressions that have gained circulation regarding the reasons for tabling these resolutions

In the first place, I had no knowledge that such resolutions were to be introduced, nor had I been asked by any one to take any position relative thereto. When they were read, however, they at once impressed me as a covert attack on the honesty of the members of the Board of Trustees, and of the officers of the Association. I consider it necessary in any organization that a few men of capacity should have the main work fall on their shoulders Such an organization would always be called by others a "machine" I do not object to this name, as a machine is understood to be an instrument for the accomplishment of work through improved methods Admitting that there is a machine in the American Medical Association, in this sense, I would certainly find in that fact nothing objectionable. I fully believe that every member of the Board of Trustees and all the officers of the American Medical Association are perfectly honest, untainted by the slightest suggestion of personal graft, and it is, therefore, a machine in which I have full confidence.

In the second place, I was impressed with the idea that this resolution was introduced for ulterior purposes by influences which were antagonistic to the present policy and conduct of our Association and its journal. In this particular, I must fully support the course pursued by the Board of Trustees and the management of The Journal, and I believe that their course is approved by 90 per cent. of the profession. I was unwilling, therefore, to countenance any scheme, under any mask, whose chief purpose was to thwart the wishes of the American medical profession and to stop the good work which had been well begun.

---

[4] The booklet on Somnos, "Somnos, a Pharmacological Report, which is referred to here, contains a "Therapeutic Index to the Usefulness of Somnos" We give below a list of diseases mentioned in this index to show the wide range of usefulness (?) that is claimed for this chloral compound Abortions Abscess—of brain, kidney, liver, tonsils, paroid gland, mediastinum; in appendicitis, glanders, perinephritic, retropharyngeal, pyemic, pelvic, ovarian Somnos lessens pain and quiets nervous state Tablespoonful, repeated once or twice Use liberally Alcoholism—full doses, repeated often Gives calm sleep No blood changes like those produced by chloral Anemias—progressive and secondary Somnos has no deleterious action on blood as is common with other hypnotics Aneurism Angina Apoplexy. Appendicitis Arthritis Arsenical poisoning Arteriosclerosis Asthma Biliary colic Bright's disease Carbuncle Carcinoma Catarrh Cellulitis Cerebrospinal fever Chlorosis Cholecystitis Chordee Chorea Cirrhosis Coccydynia Colic Colitis Concussion Confusional insanity. Contusions Convulsions Coryza Cough Cramps Cystitis Delirium Diabetes Diarrhea Diphtheria Dropsy Dysmenorrhea Dyspnea Ear Emphysema Empyema Endocarditis Endometritis Epididymitis Epilepsy Erysipelas Fevers Fistula Gallstones Gastralgia or Gastrodynia Gastritis Gonorrhea Goiter. Gout Hallucinations Hay fever Headache Heart Disease Hemicrania Hiccough Hydronephrosis Hydrophobia Hydrothorax Hyperesthesia Hysteria Indigestion Inflammation Insomnia Kidney disease Laryngitis Liver abscess Cirrhosis Lobar pneumonia Lockjaw Locomotor ataxia Lumbago Mal de mere Malarial fever Meningitis Migraine Melancholia Metritis Morphinism. Muscular rheumatism Myelitis Myocarditis Myositis Nephritis Nervous dyspepsia Neuralgia, occipito cervical, etc Neurasthenia Neuritis Night sweats Orchitis Otitis media Paresthesia Paralysis Parotitis Peliosis rheumatica Pericarditis Perimetritis Perihepatitis Perichondritis Peritonitis Pertussis Petit mal Pharyngitis Phthisis Pleurisy. Pneumonia Post epilepsy Prolapsed uterus Pseudo angina pectoris Purpura Rabies Rheumatic fever Salpingitis Sarcoma Scarlet fever Smallpox. Spasms Stomach Stomatitis Sunstroke Tenesmus Tetanus. Tonsillitis Trauma Trismus Typhoid fever. Typhus fever. Ulcers Urticaria Varicella Vomiting Vulvitis Yellow fever

Finally, it struck me as the height of impudence that the mover of the resolution should lack sufficient confidence in the House of Delegates to permit it to name its own committee, should such a committee be desired. I certainly think, with no reflection on the names therein suggested, that a committee selected from the House of Delegates itself, where each member was more or less familiar with the matter in hand, would have been a more competent committee in every way. On the whole, therefore, the entire resolutions seemed to me to be uncalled for, improper and insulting, and for these reasons I made the motion to lay them on the table. I would judge that this same impression was produced on most of the members of the House of Delegates, since my motion was immediately seconded by several and unanimously carried.

It was evident that the principal desire in the minds of the members of the House of Delegates was to dispose of the resolutions in the quickest and most effective manner possible. The idea that the Trustees or the officers of the Association opposed or in any way hindered the adoption of the resolutions is absolutely contrary to the facts of the case, and palpably absurd.

Jabez N. Jackson, M.D.

State Board Results in the Educational Number.

Springfield, Sept. 1, 1906.

To the Editor:—The data collected and tabulated in the Educational Number of The Journal (Aug. 25, 1906), gives to the medical profession a compact arrangement of facts not obtainable elsewhere, but it is to be regretted that existing conditions are not such as to render the results of your immense labor more generally satisfactory. Much may be learned by any person by a careful analysis of your figures, but at the same time many of your deductions and conclusions would convey most erroneous impressions to the casual reader. Inasmuch as the great majority of your readers will glance at your results rather than consider the conditions surrounding the origin of your data, I feel that it would be wise more emphatically to impress the fact on them that deductions based on figures which are not uniform in significance are very apt to be misleading.

The peculiar results to which we may be led by figures and statistics may be illustrated by the following brief instances: In your Table E, page 590 (Colleges Grouped by States Showing Numbers Examined and Percentages of Failures), we find that graduates of Arkansas colleges of the years 1900-1905, were successful in 100 per cent. of cases in state board examinations, while the Arkansas graduates of 1899 and previous years failed in 50 per cent. of cases. We might infer from these percentages that in mental and educational attainments, recent Arkansas graduates stood at the highest possible place in the list of all states, and infer further that the marked difference in standing between old and recent Arkansas graduates indicated an astonishing improvement in Arkansas' educational institutions. These deductions are, of course, set at naught when we find that the total number of 1900-1905 Arkansas graduates examined was one and of those of 1899 and previous years but two. Had the 1900-1905 graduate failed on examination, Arkansas would have fallen to the lowest place on the list, 46 per cent. lower than any other state. Had the one who failed of the graduates of 1899 and previous years, been successful, Arkansas would have gained the topmost place for all years, with only Connecticut and Maine in the sisterhood of supremacy. Of course, these percentages have not the slightest weight in showing the relative standing of Arkansas colleges as compared with those of other states. The same is true of Connecticut, which is given an equally exalted place. Of graduates of 1899 and previous years, Connecticut had one. He passed on examination. The effect of his failure on the percentage of Connecticut colleges in your table is obvious.

Table G (Comparison of Results Obtained by the Graduates of Colleges in Their Own States and Elsewhere), shows Dearborn Medical College with 100 per cent. of successes in Illinois and with 100 per cent. of failures in "other states." The 100 per cent. of failures in other states represents the failure of one graduate in one other state. Without consideration of this latter fact, it might not unreasonably be surmised that Illinois had licensed all graduates of a college not one of whose alumni had proven acceptable to any other state.

In the system you have adopted to facilitate comparison of the different state boards in passing or rejecting applicants, figures are used which, it would seem, are hardly susceptible of comparison. You state editorially that in Kentucky and Colorado a number of applicants have been admitted without examination and that "these are included in figuring the percentage of rejections." Those so admitted in Colorado and Kentucky, seem, however, to have been included as successful. It would appear to me that to include these applicants either as rejections or as being successful renders more confusing a table which the casual reader, at least, had assumed to be for the purpose of showing results of examining boards.

Without burdening your columns with additional details, I should suggest the following points which must be given due consideration in comparing the results of the various state boards or colleges: 1. It is impracticable to compare the showing of a college whose graduates were examined exclusively by one board with the showing of another college whose graduates were examined exclusively by another board. It is impossible to tell whether the school or the board is responsible for the results. 2. The great majority of graduates in practically all schools are examined, first at least, in the states in which the individual colleges are located. Hence, the character of the schools in each state is an important factor in considering the severity or laxity of the examining boards of the state. 3. We may as well eliminate from our data the showings of colleges whose graduates have appeared before only a small number of boards, as these showings indicate little as to the ability of the graduates of such schools to pass the average state board examination.

The importance of these points may be briefly illustrated in the following: Of the 104 colleges listed by you, there were but 10 whose graduates had appeared before as many as twenty state boards. Of this group of 10, but two are found in your Table 1—those whose candidates were rejected in less than 10 per cent. of cases before all boards. The 8 colleges are located, 1 in Maryland; 1 in Michigan; 1 in New York; 2 in Pennsylvania and 3 in Illinois. In Maryland, Michigan, New York and Illinois, from 75 to 80 per cent. of all applicants examined were graduates of schools in those states. Michigan rejected but 1.6 per cent. of her own graduates; New York 1.9 per cent. of New York graduates and Illinois 2.8 per cent. of Illinois graduates. These low percentages of rejections of the graduates of the states' own schools were due to the fact that these states have the largest number of graduates of colleges who have received high recognition in the largest number of other states. Maryland, on the other hand, rejected a much larger percentage of her own graduates, but in Maryland it is noted that the three largest schools come in your Table K—having over 20 per cent. of failures. Without the foregoing facts, it might be assumed that these states dealt with undue leniency with their own graduates.

As to the standing given by your tables to Illinois, on which the foregoing figures have considerable bearing, I desire to say a word.

Illinois does not pretend to be a state in which exactions in medical examination are unusually severe. The statutes require that the examination "shall be of a character sufficiently strict to test the qualifications of the candidate as a practitioner," and the State Board of Health endeavors to carry out the provisions of the law. If the candidate shows sufficient evidence of his ability as a practitioner, it becomes the duty of the board to grant him a certificate.

The showing that Illinois rejects a smaller percentage of Illinois graduates than of those of other states is largely due to the fact that the board is called on to examine so large a percentage of graduates of Illinois colleges whose alumni receive uniformly high grades in all states and also to the fact that but 7 per cent. of the applicants appearing before the board and coming from outside the state represent those colleges showing less than 10 per cent. of failures. A word on this subject is warranted in view of the fact that, to the casual observer, the difference between the number of rejections among graduates of Illinois colleges and from outside colleges might appear as circumstantial evidence, at least, of discrimination against those from other states.

I am not sufficiently conversant with the examination methods of other states in which this evidence of possible discrimination appears in your tables, to speak authoritatively concerning them, but I can say, without possibility of successful rebuttal, that the Illinois method of examination practically precludes the possibility or discrimination either for or against any individual, any school, or any class of applicants.

The examinations of the Illinois State Board of Health are conducted by the secretary. None of the other members of the board attends or takes part in the examination. The secretary, however, has nothing to do with the preparation of the questions or the grading of the answers. The questions are prepared and the answers are graded by the other members. The identity of the applicant is unknown to the members who grade the answers. Each applicant is identified by a number. The number given the applicant at the examination is changed in the office of the board before the papers are submitted to the members, so that the papers of each applicant are graded under an entirely different number from that given the applicant at the time of examination—a number which can not be known to the applicant. The members examining the papers do not know and can not know, until after the papers are graded, whether the applicant comes from Maine or Illinois or California, and it might be said in this connection that no member, during the ten years in which I have been secretary, has ever manifested the slightest curiosity on the subject.

The Illinois State Board of Health acts as an examining board rather than as an examining and rejecting board, and the examinations are so conducted as practically to guarantee that all those who pass have done so fairly and honestly.

JAMES A. EGAN,
Secretary Illinois State Board of Health.

[Our correspondent's comments on Arkansas' percentage are correct, as far as Arkansas is concerned, but they do not apply to Connecticut, since the latter had a total of 30 applicants examined when the former had only 3. In our editorial accompanying the tables referred to, the following statement is made: "In making comparisons, besides the percentage, one must consider also the number examined and the number of state boards before which the college was represented." This applies to practically all the tables and particularly to Tables I, J and K, and if this is kept in mind there need be no misinterpretations. Table H was arranged particularly to show comparatively rejections by examining boards, and the terms "registered" and "rejected," instead of "passed" and "failed," as well as the comments on the table should prevent any one from thinking that it was based on examination only. States which register applicants on credentials without examination would certainly appear in a wrong light if those registered in such manner were not included in figuring the percentage of rejections. The methods adopted by the Illinois board in marking papers are interesting and may be of service to other examining boards.—ED.]

A National Examining Board.

CHICAGO, Sept. 1, 1906.

To the Editor:—To the extensive and rapidly growing literature of reciprocity in medical licensure may I add another contribution for the purpose of reviewing and elaborating a suggestion already made by others of a voluntary national examination and certificate?

In the address published in THE JOURNAL, August 25, Dr. Harvey has forcibly set forth the difficulties which stand in the way of interstate reciprocity. The examinations given by over sixty state and territorial boards are, and of necessity must long continue to be, so diverse in character and severity as to afford no satisfactory basis for any general reciprocity. Nor is any scheme of compulsory national licensure possible under our form of government. At the same time it is clearly the opinion of the large majority of contributors to this discussion that an examination and certificate by some central board under the control of the national government offers the most direct and satisfactory solution of the whole question.

The way is already paved for such a plan, by the fact that in many of the states medical officers of the Army, Navy and Marine-Hospital Service are already exempted from the operation of the medical practice acts. It only remains for such an examination to be open to any and every medical graduate who might wish to take it, paying therefor a suitable fee, and for the several state boards to accept the certificate obtained by the successful candidates in such examination.

In order that the tests proposed might furnish the best possible guarantee of the competence of those examined, certain conditions would have to be fulfilled. The examiners should be experts, each in his own medical branch. The board would not, therefore, be composed of Army and Navy surgeons, although the examinations should be conducted under the auspices and control of the medical departments of the U. S. Army and Navy, who would attend to the details of arranging time and place, keeping of records, issuing certificates and the like. The actual examiners should be recruited from the ranks of those who are engaged in teaching and research in the several medical sciences who would be detached from their teaching position by leaves of absence for the limited periods necessary for this duty. In order that the burden of this work might not fall unduly on any one person, no examiner should be expected to serve more than six or twelve months consecutively. By this plan the board of examiners would be composed of a professional anatomist from one college, a physiologist from another, a chemist from another, a surgeon from a fourth, etc., each of whom is an expert in his chosen line, familiar by long experience with the purpose and methods of examining.

We must come to recognize in this country, as they do abroad, that the business of examining is one demanding special training and experience, particularly in teaching, and that examinations can not be satisfactorily made by the average general practitioners who constitute the personnel of the several state boards. Moreover, it is a "narrowing" occupation of such restricted scope that exclusive devotion to it tends to unfit the individual for its duties. A changing board, such as is here proposed, renewed by the enlistment of fresh material every few months would be much more satisfactory and effective than a permanent board.

The examinations should be exhaustive, thorough and *practical*, extending as a rule over four to six days for each applicant, and comprising, as the most important features, actual tests of his ability in the various laboratories, in the actual examination of actual patients, the performance of dissections and operations on the cadaver and the like, as is the case abroad.

The same prerequisites should be exacted of candidates as are now demanded by the better state boards, such as evidence of graduation from a recognized medical college and certificates of good moral character.

The examinations might be held at suitable intervals in five or six of the largest cities of the country, where ample facilities could be secured for conducting them. The fee exacted of the applicants should be commensurate with the comprehensive and somewhat expensive character of the examination, and with the value of the certificate to be obtained. Every candidate could well afford to pay a fee at least as large as that now exacted by any of the state boards, for a certificate which would entitle him to practice anywhere in the United States at any time. It is believed that the income from such fees would be ample to meet the expenses of the board, including the payment of adequate compensation to the examiners.

It is difficult to see how any state board could refuse to recognize a certificate obtained by such an examination conducted by such a body of men; and accept it, too, not on the basis of an I-will-if-you-will reciprocity (an attitude which can never result in reciprocal licensure without a lowering of standards), but solely on the basis of merit.

It may be objected that the proposed plan offers no relief to the old practitioner who is sometimes compelled to migrate, not from mere "wanderlust," but by force of circumstances. Something must be done for these. The flippant manner in which their claims to just treatment are discussed in some of the recent contributions on the subject and dismissed by the state boards, argues an absence of appreciation of individual rights which ill befits a judicial body—for such as an examining board in the best sense should be.

May I add another case to the several which have been reported, showing how absurd, intolerable and indefensible is the present attitude of many of the state boards? A teacher in a prominent medical college had recently been invited to take the professorship of a special branch of medicine in the medical department of the state university of a western state. On applying for a license by reciprocity with the state in which he has successfully practiced for sixteen years, he is informed that owing to a ruling adopted by the board within a month, he must take the full examination. Naturally, being nearly twenty years away from his study of the fundamental branches, he hesitates to abandon his present position and practice to remove to a distant city, in the face of the very considerable risk of failing in the kind of examination—a purely written test of his book-cramming, memorizing ability—in which case he would be ineligible to practice in that state. And so this state university must fail to secure the accession to its medical faculty of a distinguished specialist, because of a three-weeks' old arbitrary enactment of the state board of medical examiners. This practitioner, like many others, would not hesitate to undergo a practical test of his real ability to practice medicine, and such an examination as has been here suggested he might successfully pass.

This plan is not offered, however, as a means of securing reciprocity for the older practitioner, but for the recent graduate, and to serve as a means of guarding the portals of the profession for the future. For all physicians who graduated previous to 1900, let us say, reciprocity should be universal. A physician who has been licensed by any state on any basis, and who is not disqualified from practice by any breach of moral or professional conduct, should be entitled to a license by reciprocity in every other state. The public is responsible by its neglect for the present conditions—the excessive number of cheap medical colleges and the consequent abundance of incompetent practitioners. No state has very much to boast of in this regard in comparison with the other states. Much as the community may desire to purge itself, or to exclude from its borders these incompetent physicians, for the existence of which the people themselves are responsible, it has no right to seek correction of present conditions at the expense of hardship and injustice to the innocent individual physician. The courts have ruled that retroactive medical practice statutes are unconstitutional within a state. Logically they are equally unjust as between states. Time alone, and death, will remove from the community the large number of poorly trained, ignorant physicians now in the profession. It should be the business of the state boards to guard the future. The plan of a voluntary examination and certificate by a national examining board, I believe, offers the best solution of the question.

John M. Dodson.

Interstate Reciprocity and Frauds in Medical Schools.

Detroit, Sept. 5, 1906.

To the Editor:—Under the above heading Dr. Dudley Tait, of San Francisco, a member of the California Board of Medical Examiners, calls attention to the necessity of coöperation of examining boards in the investigation of medical colleges, as follows:

> In the discussion of the perplexing problem of interstate reciprocity one important phase of the question has apparently been totally overlooked: the necessity of the coöperation of examining boards in the investigation of medical colleges. Forgetful of the fact that the origin of examining boards is directly traceable to the fraudulent acts of medical colleges, boards authorized by law to go behind diplomas are notoriously prone to accept diplomas as *prima facie* evidence of regular and complete college work.

In connection with the above Dr. Tait calls attention to the point that rejection of a diploma obtained under fraudulent conditions, in which fraud both the graduate and the college of graduation were concerned, in one state would not prevent the seeking of recognition of the rejected diploma in new fields or other states. He also writes in relation to holders of diplomas rejected by his board:

> They apply for registration or examination in other states, whe their credentials are often accepted without question. Now, we California to reciprocate with these states it would, *volens no volens*, open the door to all such medical bandits, thus defeating t purpose of the law. Surely, reciprocity under these conditions ca not be founded on justice.

In commenting on the above criticism of one of the phase of medical reciprocity I can only state that it is self-eviden from his remarks that Dr. Tait is not only unfamiliar with th requirements and methods of reciprocity, but he also fails t grasp the meaning and intent of the term "reciprocity," esp cially so as applied to the endorsement of the medical licens of one state by another state on the reciprocity agreemen under the qualifications of the American Confederation of ciprocating, Examining and Licensing Medical Boards.

Medical reciprocity is not in any sense an unlimited rec procity. It is rather limited or restricted reciprocity, or i dividual reciprocity. The medical acts of nearly all of th states contain the following provision:

> Where the requirement for license shall be deemed by the boar to be equivalent to those of this act.

The recognition of the license of another state obtained (i part only) through a diploma which was not recognized by th receiving board could hardly consistently be designated a equivalent qualification, especially so if the receiving boar had a record of the fraudulent nature of the qualification o which license was obtained.

Dr. Tait evidently thinks that medical reciprocity betwee states is an unlimited recognition of the official acts of eithe board concerned in the matter of qualification for license. careful reading of the reciprocity qualifications of the Amer can Confederation would absolutely dispel this view.

In addition, also, the confederation has adopted itemize standards of preliminary and medical education, which, if i any sense lived up to, even in spirit, and are included in th reciprocity agreement between states, make it necessary fo boards in investigating applications for endorsement not onl to go behind the diploma, but also the license, and ascertain th actual quality of both.

It is possible, as in the specific case mentioned by Dr. Tai for the possessor of a defective diploma to deceive or commit fraud on a state in reciprocity with California and thereby o tain registration, but to assume that California or any othe state, having knowledge of such fraud, would, through rec procity, be obliged to recognize a license of this nature, i little less than an irresponsible statement. The mere applic tion to the California board by the applicant under such co ditions would furnish the defrauded board with the informatio on which the license could be canceled rather than endorsed.

Dr. Tait credits me with the statement that I never hav had occasion to reject a diploma from a recognized medic school. I am positive there must be some error in this stat ment, whether made by myself or by some one else. As th executive officer of my board it is my duty and practice to g behind every diploma of whatever nature presented to th board for recognition and to examine every detail of th course and work in connection with the granting of su diploma, either in direct registration or in registration throu reciprocity. It has been my duty, in connection therewith, t reject a large percentage of the diplomas presented—seldom fo fraud, in nearly all cases for defective course—even when th colleges granting the diplomas have been on the approved list.

The objections to medical reciprocity (Dr. Harvey, secretar of the Massachusetts Board of Registration in Medicine, in hi article in The Journal, August 25, entitled "The Impracti bility of Interstate Reciprocity") are based wholly, as in the case of Dr. Tait, on the defective understanding of what medical reciprocity really means as practiced and a want of knowledge of the standards of reciprocity and the method of their administration. He lays special stress on the assumed danger of the lowering of the standards through reciprocity on the theory that a state with a high standard would be obliged to receive and endorse licentiates of other states having lower standards. In this connection he states that a practitioner unable to qualify in Massachusetts, for example, could go to a state having lower requirements and then return and register in Massachusetts through reciprocity.

In connection with the above he assumes that reciprocity is an unlimited and unrestricted reciprocity and eliminates the "equal requirements" provision of the law. He also fails to recognize the qualifications and itemized standards forming the agreement between states on which reciprocity is based, and which would create a most effectual barrier against all the evils he predicts.

A mathematician attempts to demonstrate his opinion and conclusion by a statement represented by figures. In his preliminary figures, however, he makes an error by recording that twice five is fifteen; he then produces a column of figures based on this error and finally shows the result and proves his conclusion in exact form. This is exactly what Dr. Harvey has done in his article, which as a literary effort, combined with high ideals and conscientious endeavor for proper methods, is beyond criticism. He is so completely in error in regard to the range and limitations of medical reciprocity, its practical meaning, its qualifications and standards and the methods of administration, that I can only compare the conclusion attempted in his article to the result attained, by the mathematician above quoted.

His attempt to prove his conclusions through the examination statistics of state boards is also equally unfortunate. For example, he compares, among other states, the percentage of failures in examination in Massachusetts with Michigan, the former state's percentage of failures being greatly in excess of that of the latter, and asks: How can an equitable reciprocity be possible under such conditions? He is satisfied that it is impossible and impracticable.

The explanation, however, is a simple one. Massachusetts admits not only the graduates of every chartered American and foreign medical college to her board examination for license, but also undergraduates, osteopaths or any others, with or without a smattering of medical education, are admitted and examined.

Michigan, on the other hand, has an exceedingly high itemized standard of preliminary and medical education, and her list of recognized medical colleges, in consequence, is a very limited one, and an applicant for examination must be a graduate of a listed college. Through her method of standard a graduate of a recognized medical college is accepted for examination, while another graduate of the same college and of the same year may be refused such examination. If a standard provision of the medical act is effective and properly administered and the list of recognized colleges meritorious, then the percentage of failures before the state board should be almost *nil*. A large percentage of failures would certainly indicate laxness in the administrative functions, for a college examines on a maximum of standard and a board examines on a minimum of the same standard. Eliminating accidents, therefore, graduates of properly accredited medical colleges should rarely fail in a state board examination. Comparing the actual requirements of Massachusetts with those of Michigan, is it to be expected or is it even possible that the percentage of failures of the latter should in any way equal the former?

Dr. Harvey is fearful that reciprocity will result in the leveling of the high-standard state with that of the low-standard state. In the possible event of a reciprocity agreement between Massachusetts *and Michigan in the* near or distant future, I can assure Dr. Harvey that only licentiates of his board who are graduates of colleges fulfilling in every detail the preliminary and medical standard of Michigan through her recognized college list would be accepted, and that these standards would not be in any degree lowered by such a process.

Under present conditions and standards, every licentiate of Michigan at the present day could qualify for endorsement of Massachusetts, but only a small percentage of Massachusetts licentiates could qualify for endorsement by Michigan or other state with equal standard. A fair and proper comparison of products does not tend to lower the quality of such products. The old story of the two grocery stores located far enough apart to prevent comparison or competition is in evidence. The removal of one of them to close proximity to the other will not result in the clean, tidy well-kept, well-stocked and well-managed grocery descending to the status of the other, which is an unclean, untidy, ill-kept, poorly-stocked and badly-managed affair. Just the opposite would result.

If the Massachusetts board will enter into reciprocity with some of the states having higher standards and better methods than those of Massachusetts, I can assure Dr. Harvey, who is without question a consistent and conscientious advocate of *better things in* medical qualifications, that the result will make possible a standard in Massachusetts which, under past and present conditions, has been impossible. B. D. HARISON.

The Anatomy of the Ear: A Criticism.

EVANSTON, ILL., Sept. 1, 1906.

To the Editor:—An article on "The History of the Mastoid Operation," by Dr. Frank Allport, in THE JOURNAL, July 14, 1906, contains certain errors regarding the anatomy of the ear that should not be allowed to pass unchallenged.

In the first place, the term middle ear is repeatedly confused with the tympanum and the two terms used as synonyms, whereas the cavum tympani is but a part of the series of cavities that make up the middle ear. The middle ear includes all the series of connected cavities extending from the opening of the Eustachian tube in the pharynx to the most remote mastoid cell.

In the second place, the antrum is frequently referred to as a mastoid cell. This is not at all the case. The antrum is quite distinct developmentally and pathologically from the so-called mastoid cells and as its scientific name, "Antrum tympanicum" implies, is a part of the tympanum as are also the recessus epitympanicus and recessus hypotympanicus.

On page 96 the following statement occurs: "Above the foramen ovale and at the angle of the inner tympanic wall and the roof or tegmen runs forward the bony portion of the Eustachian tube, its roof being continuous with that of the tympanum, aditus ad antrum and antrum." The author has confused the canal for the tensor tympani with the Eustachian tube. The bony plate forming the tegmen does not form any part of the roof of the Eustachian tube. The Eustachian tube lies directly beneath the canal for the tensor tympani.

The drawings for Figures 8, 9 and 10 are reproductions of drawings from Deaver's work on anatomy for which no credit is given, and are inaccurate and misleading in many ways as will be apparent to any one who has made a study of the relations of the parts represented. G. W. BOOT, M.D.

The Anti-Nostrum War Is Right.

SAINT LOUIS, Sept. 10, 1906.

To the Editor:—Just a word to express my endorsement of your editorial September 8. When I compare present conditions with what we have had a few years ago, the better organization, the increased *esprit de corps*, the local interest, the aggressive nostrum war and the "mute but eloquent" proof which comes to us with every issue of THE JOURNAL, I would be false to my ideas of right did I not express my appreciation.

The policy of THE JOURNAL toward the "patent-medicine" interests and those who support them is right. Its campaign in effecting local organizations and in building up state associations is right. *Its successful work in giving* us the best and most complete presentation of literature which we need each week is right. I know I am the better, the A. M. A. better, and THE JOURNAL better and more prosperous than ever before. "Let the galled jade wince," and let us lose no sleep.

WILLIAM PORTER.

Book Notices

UNCONSCIOUS THERAPEUTICS, or the Personality of the Physician. By A. T. Schofield, M.D., M.R.C.S. Second edition. Cloth. Pp. 317. Price, $1.50. Philadelphia: P. Blakiston's Son & Co., 1906.

The physician of to-day, perhaps more than any time in the past, is reminded of the value of the psychic element in therapeutics. That the profession takes some heed to these reminders is apparent by the appearance within two years of a second edition of Dr. Schofield's work. It covers the subject of the value to the physician of the impression that he makes consciously and unconsciously on the mind of his patient. The facts are, we might say, of universal recognition, but there are some of us in the profession who seem to need reminders of them from time to time. Perhaps some of us suffer under a disadvantage of a more correct appreciation of our limitations than others whose success is greater, with lesser qualifications. A little knowledge is said to be a dangerous thing but more is sometimes worse, as far as pecuniary success is concerned. The reading of this work ought to be profitable to very many of our profession and what Dr. Schofield says about the advisability of more attention being given to the subject of mental therapeutics in our medical instruction is very largely true. It does not follow that we should use quackish methods or deceive our patients—and the physician who does not have faith in scientific methods or who is a therapeutic nihilist is in danger of not being so very far removed from a quack. We know that we can do things for the benefit of our patients by material methods and should cherish our faith in them. Good looks and self confidence are not everything in medical practice, Mephistopheles to the contrary, notwithstanding. We mention this matter not because we think Dr. Schofield ignores it. but because in noticing a work like this one should perhaps guard against any overestimation of the special points which it so well and usefully emphasizes. The book is exceedingly readable and its occasional perusal will be interesting as well as probably useful in otner ways. It is certainly full of valuable suggestions by which some of us may profit.

A NURSE'S HAND-BOOK OF MEDICINE. By J. N. Henry, M.D., Clinical Professor of Medicine, Woman's Medical College of Pennsylvania. Cloth. Pp. 268. Price, $1.50. Philadelphia: J. B. Lippincott Company, 1906.

This book comprises the lectures delivered to the nurses of the Pennsylvania Hospital during the last four years. It deals entirely with medical cases and with the care of children. The chapters on personal hygiene and the hygiene of the sick room are practical, as also is the chapter on hypodermic medication, catheterization and the use of the stomach tube. The chapter on diet contains a number of good recipes, for which the author acknowledges his indebtedness to Miss Walker and to Miss Byerly of the Pennsylvania Hospital.

A COMPEND OF OPERATIVE GYNECOLOGY. Based on Lectures in the Course of Operative Gynecology on the Cadaver at the New York Post-Graduate Medical School and Hospital, delivered by W. S. Bainbridge, M.D., Adjunct Professor of Operative Gynecology on the Cadaver, New York Post-Graduate Medical School and Hospital, etc., Compiled with Additional Notes, in Collaboration with Harold D. Meeker, M.D., Instructor in Operative Gynecology on the Cadaver, New York Post-Graduate School, etc. Cloth. Pp. 66. Price, $1.00 net. New York: The Grafton Press, 1906.

This book is intended to serve as an aid to students in operative gynecology on the cadaver. The various operations are briefly described. The book concludes with "Miscellaneous Points," in which the different forceps, needles and methods of inserting sutures, of making incisions and of controlling hemorrhage are discussed.

Marriages

WILLIAM B. NYE, M.D., West Newark, Ohio, at Newark, August 30.

B. F. ZOBRIST, M.D., Jewett, Ill., to Miss Lillie A. Apple of Keysport, Ill., September 4.

HARVEY BRINTON STONE, M.D., Baltimore, to Miss Ethel Hoffman, at Baltimore. August 27.

EDWIN A. REISENFELD, M.D., to Miss Reta Kratzenstein, both of New York City, September 4.

THEODORE A. LAFFERTY, M.D., New Baltimore, Mich., to Miss Mabel Lindahl of Detroit, August 30.

CARL WILHELM YOUNG, M.D., Philadelphia, to Miss Freida Rippelmeyer of Baltimore, August 22.

LOUIS H. RUEGNITZ, M.D., Webster City, Iowa, to Miss Grace Kilburn Meigs of Chicago, September 3.

CHARLES BURR CALDWELL, M.D., Bethany, Ill., to Miss Lydia Stevenson of Monticello, Ill., August 30.

GEORGE BURNSIDE STOREY, M.D., to Miss Grace Edna Watkins, both of Portland, Ore., September 5.

ALBERT GEORGE JENNER, M.D., Milwaukee, to Mrs. Birdie M. Weston of St. Louis, at Chicago, August 28.

MARVIN D. HUBBELL, M.D., New York City, to Miss Alma Hathaway Jones of St. Louis, September 1.

HENRY BASCOM THOMAS, M.D., Chicago, to Miss Louise Downing Wendell of Louisville, Ky., September 5.

HAL BAILEY BROWNELL, M.D. Buffalo, N. Y., to Miss Irene Helen Trowbridge of Toledo, Ohio, September 1.

ANSON LE ROY NICKERSON, M.D., Momence, Ill., to Miss Laura May Chesney of Bucyrus, Ohio, August 29.

WILLIAM PROVINCE GARSHWILER, M.D., Indianapolis, to Mis Florence Maria Province of Franklin, Ind., September 12

Deaths

Millard P. Sexton, M.D. University of the State of Missouri, Medical School, Columbia, 1880; a member of the American Medical Association, Medical Society of the State of Missouri, Kansas City District Medical Society and Jackson County Medical Society; secretary of the Eastern Kansas Medical Society: fellow of the Kansas City Academy of Medicine; professor of diseases of the mind and nervous system in the College of Physicians and Surgeons, Kansas City, Kan.; formerly physician to State Hospital for the Insane No. 1, Fulton; superintendent of the Bonner Springs (Kan.), Sanatorium; neurologist to Bethany Hospital, Kansas City, Kan., died at St. Luke's Hospital, Denver, September 5, after a short illness aged 50.

Edith Warner Cadwallader Crowder, M.D. Woman's Medica College of Pennsylvania, Philadelphia, 1900; formerly a member of the American Medical Association and of the Philadelphia County Medical Society, and professor of obstetrics in th Woman's Medical College of Pennsylvania, died at her home i Chicago, Aug. 18, 1906. On her marriage to Dr. Thomas F Crowder of Chicago, in October, 1905, all her medical appointments were resigned.

Samuel A. Buchanan, M.D. Department of Medicine of th University of Pennsylvania, Philadelphia, 1893: a member o the American Medical Association, Medical Society of the Stat of Pennsylvania and Philadelphia County Medical Society surgeon of the Baltimore & Ohio and Pennsylvania Systems died in the Polyclinic Hospital, Philadelphia, August 26, from septicemia, after a prolonged illness, aged 40.

Ludwig H. Van Ghoren, M.D. Charity Hospital Medical College, New Orleans, 1876; at one time a member of the New Orleans board of health; for several terms a member of th City Council of Bay St. Louis, Miss.; mayor pro tem and a member of the board of health of the city, died at his home August 31, after an illness of nearly a year, aged 62.

David V. Yerex, M.D. Bellevue Hospital Medical College, New York City, 1869; a prominent and influential citizen of Imlay City, Mich.; for two years member of the Lapeer County poo board, died in Harper Hospital, Detroit, August 27, four day after an operation for intestinal obstruction, from shock without having regained consciousness, aged 61.

George Mackie, M.D. Long Island College Hospital, Brooklyn 1874; a member of the American Medical Association, th Massachusetts Medical Society and Bristol County Medica Society; one of the most prominent and esteemed physicians o southeastern Massachusetts, died at his home in Attleboro Mass., August 31, after a short illness, aged 56.

Abram Irvin Clarke, M.D. University of Virginia, Medica Department, Charlottesville, 1845; who served for severa terms as a representative from Campbell County, Va.; some time president of the board of health of Lynchburg and of the Lynchburg Academy of Medicine; the oldest physician of the city, died at his home, August 31, aged 89.

Alexander K. MacLean, M.D. Toronto University, 1897, of Chicago; professor of otology, rhinology and laryngology in the Chicago Eye, Ear, Nose and Throat College, and instructor on diseases of the eye, ear, nose and throat in the Illinois Medical College, Chicago, died from acute dysentery at Battleford, Sask., August 12.

James A. Finn, M.D. Harvard University Medical School, 1875, of Roxbury, Mass.; for 28 years attending physician to the Home for Deaf Mute Catholic Children, and for many years medical examiner to the House of the Good Shepherd and St. Vincent's Infant Asylum, died in Carney Hospital, Boston, September 1, from cancer.

Orlando Miller Woodrow, M.D. Kentucky School of Medicine, Louisville, 1894; a member of the American Medical Association and of the Jackson County (Ohio) Medical Society; a practitioner of marked ability, died at his home in Wellston, Ohio, August 24, from brain abscess, after an illness of three years, aged 38.

Arthur Barlow, M.D. Memphis Hospital Medical College, of Willow Hole, Texas; a member of the Madison County (Texas) Medical Society and of the Brazos Valley Medical Society, died at Zulch, Texas, March 29, from uremic poisoning, after an illness of one week, aged 40.

lumbus G. Slagle, M.D. University of Louisville Medical Department, 1861, a member of the American Medical Association and an old resident and practitioner of Minneapolis, Minn., died at his home in that city, August 27, from heart disease, after a short illness, aged 72.

Richard Rush Hanley, M.D. Jefferson Medical College, Philadelphia, 1852; a member of the first board of supervisors of Fremont County, Iowa, and for several years justice of the peace at Tabor, died at the home of his son in Shenandoah, Iowa, August 4, aged 77.

Henry C. Thatcher, M.D. Eclectic Medical Institute, Cincinnati, 1887, of Youngstown, Ohio, a specialist on diseases of children, died at the Mahoning Valley Hospital, Youngstown, from spinal tuberculosis, September 2, after an illness of two years, aged 40.

Neilson Abeel Baldwin, M.D. Medical Institution of Yale College, New Haven, 1861, of Brooklyn, N. Y.; a member of the American Academy of Medicine, died in Seney Hospital, Brooklyn, August 29, after a surgical operation, aged 67.

Clement Clay Greene, M.D. Southern Medical College, Atlanta, Ga., 1881, formerly a widely known practitioner of Atlanta, Ga., who had been an invalid for about six years, died in his apartments in Atlanta, September 2, aged 49.

Harriet S. French, M.D. Penn Medical University, Philadelphia, 1865, said to have been the oldest woman practitioner in Philadelphia, died at her home in that city, from heart disease, following a cerebral hemorrhage, September 5, aged 82.

Daniel Ream, M.D. Eclectic Medical Institute, Cincinnati, 1867; state senator in 1872, and formerly sheriff and coroner of Siskiyou County, Cal.; for more than 50 years a practitioner of Yreka, died at his home in that city, September 1.

Isidore Fregeau, M.D. Ecole de Médécine et de Chirurgie, Montreal, 1861; for one term a member of provincial parliament from Sherbrooke County, died at his home in Sherbrooke, Quebec, September 2, aged 72.

Ira W. Johnson, M.D. Mobile (Ala.) Medical College, 1906; a member of the Shelby County Medical Society, died at his home in Calera, Ala., August 5, from the effects of an overdose of tincture of aconite root, aged 25.

John Henry Weaver, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1873, of Altoona, Pa., died at the home of his son in Greensboro, Md., from cerebral hemorrhage, August 18, aged 75.

Ernest Woolfolk, M.D. University of Virginia Medical Department, Charlottesville, 1876, died at his home in Thornhill, near Lahore, Va., August 25, from disease of the stomach, after a long illness.

Benjamin E. Hays, M.D. Bellevue Hospital Medical College, New York City, 1870, of New York City, a veteran of the Civil War, died in the Presbyterian Hospital, New York, August 19, aged 69.

James A. Leech, M.D. Columbus (Ohio) Medical College, 1886, workhouse physician of Columbus, Ohio, died at the home of his sister in Cambridge, Ohio, from an overdose of morphin, August 29, aged 43.

Alexander Thomasson Dozier, M.D. Louisville Medical College, 1849, who had given up practice for a number of years, was accidentally burned to death in Auburn, Cal., Dec. 25, 1905, aged 84.

William B. Watkins, M.D. University of Louisville Medical Department, 1857, one of the most prominent practitioners and citizens of Clay County, Miss., died at his home in Big Springs, August 31.

Albert Whitlock, M.D. Pulte Medical College, Cincinnati, 1878, died at his office in Wichita, Kan., August 31, from hemorrhage of the lungs, after an illness of about four months, aged 50.

Edward J. Chapman, M.D. Rush Medical College, Chicago, 1871, died at his home in Missouri Valley, Iowa, August 28, from locomotor ataxia, after an illness of four years, aged 61.

Henry Austin Gould, M.D. 1874, a former practitioner of Hammond, Wis., died in Minneapolis, August 7, from cholera morbus and nephritis, after an illness of two days, aged 82.

Andrew Klingberg, M.D. Rush Medical College, Chicago, 1869, died at his home in Osage City, Kan., August 10, from nephritis, after an illness of about three years, aged 67.

J. Thompson Morton, M.D. Medical College of Georgia, Augusta, 1900, of Keysville, Va., died from typhoid fever in a hospital in Richmond, Va., August 30.

Harry L. Helper, M.D. Department of Medicine of the University of Pensylvania, Philadelphia, 1888, died at his home in Reading, Pa., August 18, aged 43.

Charles E. Howland, M.D. Eclectic Medical Institute, Cincinnati, 1865, died at his home in Adrian, Mich., September 1, after a lingering illness, aged 75.

Henry F. Graetzel, M.D. Baltimore University School of Medicine, 1893, died at his home in Baltimore, August 30, from disease of the stomach, aged 76.

Charles W. Musgrove, M.D. Jefferson Medical College, Philadelphia, 1879, died at his home in McEwensville, Pa., July 29, after a long illness, aged 62.

Justus Beebe (Examination, Michigan), died at his home in Wixom, Mich., April 22, from angina pectoris, after an illness of three days, aged 68.

John Jay Higgins, M.D. College of Physicians and Surgeons in the city of New York, 1850, died at his home in New York City, August 28, aged 79.

James Ambrose Osborne, M.D. Hahnemann Medical College and Hospital, Chicago, 1897, died recently at his home in Harmony, Pa., aged 35.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

MERCURY SOZOIODOLATE.

Kwang Ju, Korea, Aug. 2, 1906.

To the Editor:—Please tell me what Lengfeld's solution is. How is it used in syphilis?

J. W. Nolan.

Answer.—Probably our correspondent refers to a solution of mercury sozoiodolate recommended by Dr. Garceau of San Francisco in an article published in the *Journal of Cutaneous Diseases,* June and July, 1906, and prepared for him by F. Lengfeld, chemist. This solution contains 0.5 per cent. of mercury as sozoiodolate held in solution by sodium iodid. This proportion is advantageous in that one can calculate the amount of mercury, since each twenty minims contains 1/10 of a grain of mercury. The sozoiodolate of mercury dissolves in 500 parts of water, but is readily soluble in solutions of sodium chlorid or of other halogen salts. It is a fine yellow powder which should dissolve with slight turbidity to the extent of 0.5 gm. (7½ gr.) in 30 c.c. (one ounce) of water on the addition of 1.5 gm. (22½ gr.) of comon salt. The following formula is given by Hager (Handbuch der Pharmaceutischen Praxis) as suitable for hypodermic injection:

℞.	Hydrargyri sozoiodolatis	gr. xii	|8
	Potassi iodidi	gr. xxiv	1|6
	Aquæ dest.	℥iss	10|

M. Sig.: For subcutaneous injection.

To produce the strength specified by Garceau we need a solution containing 1,336 per cent. of sozoiodolate. Using the same relative proportion of sodium iodid as of potassium iodid in the above formula we arrive at the following formula, which must closely represent the formula of Garceau in the article referred to:

℞.	Hydrargyri sozoiodolatis	gr. 2.4		156
	Sodii iodidi	gr. 4.8		312
	Aquæ dest.	gr. 150	10	

Sozoiodolate of mercury, a mercury salt of di-iodo-paraphenolsulphonic acid, $C_6H_2.OH.I_2.HSO_3$, is to be obtained of the various dealers in chemicals. Twenty minims of the solution are injected into the buttock with the usual precautions for asepsis. Swabbing with ether may be used to cleanse the skin and at the same time produce a mild anesthesia. A trochar needle is quickly plunged into the gluteus muscle, the trochar removed, and, if there is *no oozing from the wound*, the barrel of the syringe is attached to the needle and the injection made. Massage of the site of injection relieves pain materially and tends to prevent nodulation.

COMPARATIVE VALUES OF SILVER PREPARATIONS.

JEFFERSON CITY, MO., Aug. 21, 1906.

To the Editor:—Will you please give in your "Queries and Minor Notes" the relative and comparative germicidal value of "protargol," "argyrol," and "nargol," as found by disinterested parties, by both laboratory and clinical tests? Argyrol, I know, is less irritating, but has it the same germicidal properties, grain for grain, when compared with protargol? J. A. HILL.

ANSWER.—In the discussion on a paper by Myles Standish in THE JOURNAL, June 17, 1904, page 1854, the comparative values of silver nitrate, protargol and argyrol in the treatment of purulent conjunctivities are considered. The consensus of opinion was that the effectiveness of protargol and argyrol is about the same, except in gonorrheal opthalmia, when the cornea is involved, in which case better results seem to be obtained with protargol. It has been assumed by S. Fränkel (Arzneimittel-Synthese, 2d edition, p. 611) that the germicidal value of freely soluble compounds of silver with albumins depends on the percentage of silver which they contain. The recent report (see abstract, p. 398, this issue) of Marshall and Macleod Neave to the therapeutic committee of the British Medical Association, however, indicates that the bactericidal power has no definite relation to the percentage of silver since they found that argyrol, which is said to contain 25 per cent. of silver, produced very little bactericidal effect. while nargol, containing 10 per cent., and protargol, containing 8 per cent., were strongly bactericidal, and of about equal value.

LACTOPHENIN AND ASPIRIN.

CORONADO BEACH, CAL., Aug. 24, 1906.

To the Editor:—Will you kindly publish in THE JOURNAL some reliable information regarding lactophenin and aspirin, especially as to their pain relieving properties. The literature I have received from the proprietors of these preparations is written by obscure *men, and, as it is uniformly favorable, it is,* in my opinion, unreliable. X. Y. Z.

ANSWER.—Lactophenin is chemically very similar to phenacetin. While phenacetin is acetparaphenetidin, lactophenin is lactparaphenetidin; while phenacetin contains an acetic acid group, lactophenetidin contains a *lactic acid group*, and because of this lactic acid group, the compound is more soluble than phenacetin. Therapeutically also it is similar to phenacetin, and possibly it acts somewhat more energetically because of greater solubility. Aspirin is acetyl-salicylic acid and is produced by heating together salicylic acid and acetic anhydrid or chlorid. It is not changed in the stomach, but is decomposed in the intestine, forming a salicylate. It may be regarded as a useful substitute for salicylic acid, possessing essentially the same sphere of therapeutic action, with certain advantages over the older drug, the chief being that it is not decomposed in the stomach, and hence is not so likely to give rise to gastric irritation. H. C. Wood says: "It has been used by good clinicians with asserted good results, to depress the temperature in fevers, and has been highly praised as a means of subduing pain in migraine, neuralgia, and even in the fulgurant agonies of locomotor ataxia." Some by-effects have been reported by O. Meyer (*Deutsch. med. Wochnschr.*, vol. xxxix, No. 7) and Winckelmann (*Muench. med. Wochnschr.*, vol. l. No. 42). R. Freund reports three cases of drug eruptions occasioned by it (*Muench. med. Wochnschr.*, vol. lii, No. 15, April 11, 1905). It is controlled by *patent in the United State*, but not elsewhere. The consequence is that in this country the use of a very valuable therapeutic agent is restricted by its unnecessarily high price as compared with the prices in foreign countries, where it is not protected by patent.

A STRYCHNIN TOXIN.

TOLEDO, O., Sept. 6, 1906.

To the Editor:—Kindly tell me whether there is a toxin which produces the following train of symptoms: During our warmest weather a man had, for a week, so much soreness along the entire length of the spinal column that in the morning he had difficulty in getting out of bed; but after he had forced himself to get up, and had moved around for a time, he had, during the rest of the day, only an aching sensation in his back. After a warm bath in the morning he began to perspire profusely, felt a little nauseated, and in about half an hour began to have tonic muscular contractions in the right arm, and in the course of an hour the contractions had involved all of the voluntary muscles of the body, excepting those of the face. The contractions would last as long as a half minute sometimes, but generally were of shorter duration. The flexors and extensors seldom contracted at the same time; the forearm, for example, would be very strongly flexed on the arm for a while, when those muscles would let go, and the extensors would suddenly just as powerfully straighten the arm, making him strike the back of the hand on the floor until his hands were bruised by the blows. He was entirely rational and conscious all of the time, and when an arm or leg or any part of the body was in the spasm, would want it rubbed as hard as a strong man could rub it. The muscles of the arms, legs and back seldom contracted at the same time, though they were sometimes in spasm at the same time. Opisthotonos was often very marked; and he complained occasionally of the tongue drawing- just like his arms. The muscles might all remain quiet for five minutes, and again might contract a half dozen times in three minutes. The day that the convulsions came on was one of the warmest of the season. He was on the floor, and said that ice rubbed along the spinal column was very grateful to him. One grain of morphin given hypodermically within an hour did not relieve the contractions, but chloroform did so. After the first day ½ grain of morphin morning and evening controlled most of the contractions, though any movement of the body was likely to cause momentary contractions some place. There were no eye symptoms, and until the end of the third day he had no temperature; then for two days it was 100, then went to normal, where it remained. Now, at the end of two weeks since the attack, all of the muscles, except the large muscles of the back, are free from pain and soreness; but any use of the back muscles causes him pain about as they did the week before the spasms of the muscles came on. Thinking that the man was being poisoned from some source, and most likely from the intestinal tract, he was given, all through his sickness, 15 grains of acetozone every twenty-four hours. Drs. McVetey and Kirkley saw the man in consultation, and if there is a toxin which will cause such symptoms, we will be obliged if you will tell us what it is, and where we can find it described. J. L. TRACY.

ANSWER.—Strychnin-like substances have been isolated from decomposing organic mixtures, especially from moldy corn meal. The substance obtained from corn meal is really a mixture of ptomains which give color reactions similar to strychnin, but the physiologic action of some of them is very different from strychnin. Selmi was able to extract from corn meal a base which produced tetanic convulsions and also gave reactions similar to strychnin, but differed from it in the fact that it could not be extracted with ether. A base obtained by Gautier and Etard from decomposing flesh produces tetanic convulsions toward the end of its action (Vaughan and Novy, "Ptomains and Leucomains," 3d edition, 1896, p. 316). Tetanin has been isolated by Brieger from cultures of tetanus bacilli (Ibid., p. 398), and produces most of the symptoms of tetanus. C. P. Howard states (*Amer. Jour. Med Sci.*, February, 1906), that Ewald has isolated a peptotoxin from the urine in cases of tetany. In cases like the one described, it is probable that the toxin is produced in the alimentary canal, provided of course, that the case is one of toxemia. Care should be taken in making the diagnosis to distinguish from strychnin poisoning, tetanus, possibly hysteria and tetany. For the diagnosis of the latter see Howard's article.

THE PHYSICIAN'S LIBRARY AND THE FILING OF CLIPPINGS FROM JOURNALS.

WHITEWRIGHT, TEX., Aug. 31 ,1906.

To the Editor:—To the suggestions embodied in your reply to Dr. E. A. Hines in THE JOURNAL, Aug. 25, 1906, allow me to add that I find it easy to preserve and find all my medical literature. To do this it is necessary only to procure an ordinary straight punch, some stiff cardboard, and cheap shoestrings. I punch a pair of holes at the top and two at the bottom of the back of each number, and file it on the loops of shoestrings and tie. I string on and tie each number as it comes from the mail, and when the index arrives I put it on, and then the last cardboard for the back. My weekly medical literature constitutes by far the most important part of my library. For instance, after reading the article in THE JOURNAL, Aug. 18, 1906, on "The Relations of Gastric Acidity to Gastric Symptoms," I immediately turned to my text-book on "Diseases of the Stomach," now two or three years old, and annotated on the margin: "J. A. M. A., Aug. 18, '6, p. 496." There is room along the margins for indices of the important current articles for four or five years. Using this method I do not mutilate my weekly periodicals.

S. H. LANDRUM, M.D.

GALVA, KAN., Aug. 27, 1906.

To the Editor:—Noticing the query of Dr. Hines and your answer in THE JOURNAL, Aug. 25, 1906, page 609, I should like to recommend a method I have used for a number of years and found very satisfactory. It was given me by one of my instructors in college, Dr. Hickey, of Denver. It consists in making a note on the margin of the page treating of that particular subject in the text-book most often referred to, of the name or initials, volume and page of the journal in which the article to be referred to is to be found. For example, in an old edition of Osler, under etiology of smallpox, opposite the sentence, "The nature of the contagion of smallpox is still unknown." I have this reference: J. A. M. A., vol. xl, pp. 1221 and 1233. This refers to Dr. Councilman's report of the discovery of the germ of smallpox. By this method physicians can keep their text-books constantly up-to-date.

C. D. Weaver.

Durand, Ill., Sept. 4, 1906.

To the Editor:—In reply to your correspondent in the issue of August 25, I would suggest a plan that I have followed for several years of indexing my journal reading. It is simple, practical, and requires but a very short time to make an entry, and although it sometimes takes a little time to find the reference if it is far back and there is much uncertainty as to when I read the article, still it serves the purpose admirably. I procure a small blank book and keep it convenient to my reading desk. When I read an article that I may want to refer to again I enter the title in my blank book in black ink, under that the name of the author and the journal, giving volume number and date in red ink. The following is a sample, letting italics indicate red ink:

Some Phenomena of Tuberculosis Infection.
Wm. Porter, A.M., M.D.
J. A. M. A., xlvi, 21, 5-26-'06, p. 1573.

If some time later I wish to look up the article by title I run my eye over the pages, observing only that in black ink; if by the author, I carry my eye over the red ink only. When a volume of each journal is complete I tie it in a bundle, attach a tag on which is written the name of the journal, the volume and the dates of the first and last numbers, and shelve them where they are convenient of access. Thus each volume of a journal becomes a part of my library, and almost as easy to consult as a bound volume.

George M. Haines.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Sept. 8, 1906:

Loving, R. C., and Whaley, A. M., asst.-surgeons, granted leave of absence for one month and authorized to return to the United States via the Suez Canal on one of the transports to leave Manila, P. I., for New York City, on or about Sept. 1, 1906.

Boyer, Perry L., asst.-surgeon, left Camp of Instruction, Austin, Texas, with 2d Battalion Field Artillery, marching to Fort Sam Houston, Texas.

Fife, J. D., asst.-surgeon, reports departure from Fort Slocum, N. Y., on detached duty with recruits, and on arrival at Boise Barracks, Idaho, to avail himself of seven days' leave of absence.

Bartlett, C. J., asst.-surgeon, relieved from further duty at Camp of Instruction, Murray, Washington, and ordered to report to the commanding general, Department of California, for duty.

Havard, Valery, asst.-surgeon general, on adjournment of the Association of Military Surgeons, Buffalo, N. Y., will proceed to Camp Roosevelt, Mount Gretna, Pa., for observation of the medical department in the field and inspection of new sanitary methods and appliances in use at the camp; on the completion of this duty he will proceed to Camp of Instruction at Fort Benjamin Harrison, Ind., for similar duty, and then return to his proper station.

Mason, C. F., surgeon, will proceed to Camp Chickamauga, Ga., to observe the methods of instruction and organization of the medical department in the field, and to inspect the new sanitary methods and applances in use at the camp; on the completion of this duty he will return to his proper station.

Darnall, C. R., asst.-surgeon, will proceed to the Camp of Instruction at Fort Riley, Kan., for observation of the methods of instruction and the organization of the medical department in the field, and to inspect the new sanitary methods and appliances in use at the camp; on the completion of this duty he will return to his proper station.

Phalen, J. M., asst.-surgeon, left Camp of Instruction, near Austin, Texas, en route to station, Fort Logan H. Roots, Ark.

Miller, E. W., asst.-surgeon, left Camp of Instruction near Austin, Texas, with the 1st U. S. Cavalry, en route to station, Fort Clark, Texas.

O'Reilly, R. M., brig.-gen., reappointed Surgeon-General, U. S. Army, for the period of four years, from Sept. 7, 1906.

Arthur, W. H., surgeon, granted ten days' leave of absence.

Purnell, H. S., asst.-surgeon, leave of absence extended one month.

Byars, C. R., cont.-surgeon, returned to duty at Jefferson Barracks, Mo., from practice march with 3d Squadron, 9th Cavalry.

Stone, F. P., dental surgeon, left Camp Mabry, Austin, Texas, for Fort Sam Houston, Texas.

McCallum, F. M., cont.-surgeon, granted leave of absence for one month, to take effect on his relief from his present duties.

Carpenter, Alden, dental surgeon, left Vancouver Barracks, Wash., and arrived at Camp Tacoma, Wash., for the purpose of attending to the necessary dental work of officers and enlisted men at that camp.

Jordan, E. H., left Denver for San Francisco to take transport to sail for Philippine Islands, Sept. 5, 1906.

Whinnery, J. C., dental surgeon, left Fort Flagler, Wash., and arrived at Vancouver Barracks, Wash., for duty.

Daywalt, cont.-surgeon, sick leave of absence extended one month.

Leeper, J. F., cont.-surgeon, returned to duty at Fort Duchesne, Utah, from Camp of Instruction near Fort D. A. Russell, Wyoming.

Chase, A. M., cont.-surgeon, left Camp of Instruction near Austin, Texas, with 1st Cavalry, en route to his station, Fort Reno, Oklahoma.

Stone, F. P., dental surgeon, granted fourteen days' leave of absence.

Van Kirk, H. H., cont.-surgeon, left Fort Sill, Okla., on leave of absence for one month.

Thorp, C. W., cont.-surgeon, returned to duty at Fort Ethan Allen, Vermont, from leave of absence.

Wolven, F. H., dental surgeon, left Fort Terry, N. Y., and arrived at Fort Trumbull, Conn., for duty.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Sept. 8, 1906:

Medical Director R. A. Marmion, to be placed on the retired list of officers of the navy, Sept. 6, 1906, in accordance with the provisions of Section 1444 of the Revised Statutes.

Surgeon L. W. Curtis, detached *Pensacola*, Naval Training Station, San Francisco, etc.; to home and wait orders.

Surgeon C. E. Riggs, detached Navy Yard, New York, N. Y., etc.; to *Pensacola*, Naval Training Station, San Francisco, and additional duty Naval Training Station.

Asst.-Surgeon P. T. Dessez, detached *Severn*, to home and wait orders.

Asst.-Surgeon J. O. Downey, to Naval Hospital, Philadelphia.

Passed Asst.-Surgeon C. N. Fiske, detached *Marblehead*, when out of commission; to *Yorktown*.

Passed Asst.-Surgeon, G. M. Mayers, detached Navy Yard, Washington, D. C., etc.; to *Marietta*.

Acting Asst.-Surgeon E. P. Huff, appointed as acting assistant surgeon in the navy from Aug. 31, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Sept. 5, 1906:

Sawtelle, H. W., surgeon, directed to report to chairman of board of medical officers, Washington, D. C., September 4, for physical examination.

Stoner, G. W., surgeon, directed to proceed to Washington, D. C., for special temporary duty, on completion of which to rejoin station.

Mead, F. W., surgeon, directed on expiration of leave of absence, to proceed to Savannah, Ga., and assume command of service at that port.

Carrington, P. M., surgeon, granted three days' leave of absence from Sept. 3, 1906, under provisions of Paragraph 189 of the Service Regulations.

Williams, L. L., surgeon, leave of absence granted for one month and fifteen days, from July 16, 1906, amended to read nineteen days from July 16, 1906, and five days from Aug. 19, 1906, in all twenty-four days.

Guiteras, G. M., surgeon, directed to rejoin station at Cairo, Ill.

Hough, J. Spencer, acting asst.-surgeon, granted leave of absence for thirty days, to be taken on or about Oct. 15, 1906.

Thomas, A. M., pharmacist, granted leave of absence for fifteen days from Sept. 9, 1906.

BOARDS CONVENED.

Board of officers was convened to meet at the Bureau, Washington, D. C., Sept. 4, 1906, to determine whether or not the physical condition of Surgeon H. W. Sawtelle is such as to entitle him to "waiting orders." Detail for the board: Asst.-Surgeon General J. M. Eager, chairman; Asst.-Surgeon General J. W. Kerr, Surgeon L. L. Williams, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Sept. 7, 1906:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, Aug. 18-25, 7 cases.
New York: New York, Aug. 18-25, 3 cases.
Ohio: Cincinnati, Aug. 24-31, 1 case.
Pennsylvania: Sunbury, July 4, 1 case.
Texas: Houston, Aug. 18-25, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, July 14-28, 30 cases.
Canada: Toronto, Aug. 18-25, 1 case.
France: Paris, Aug. 4-11, 7 cases.
Great Britain: Liverpool, Aug. 18-25, 2 cases.
India: Bombay, July 24-Aug. 7, 3 deaths; Calcutta, July 14-28, 21 cases; Karachi, July 24-Aug. 5, 7 cases, 2 deaths; Madras, July 21-Aug. 3, 5 deaths; Rangoon, July 14-21, 2 deaths.
Japan: Kobe, July 14-21, 1 case.
Russia: Moscow, Aug. 4-11, 2 cases, 2 deaths; Odessa, Aug. 4-18, 8 cases; St. Petersburg, July 28-Aug. 4, 1 case, 1 death.
Siberia: Vladivostok, July 14-21, 2 cases, 1 death.

YELLOW FEVER.

Cuba: Havana, Sept. 3-8, 1 case, 1 death.
Mexico: Merida, Aug. 12-25, 10 cases, 5 deaths; Vera Cruz, Aug. 19-25, 1 case.

CHOLERA.

India: Bombay, July 24-Aug. 7, 207 deaths; Calcutta, July 14-28, 19 deaths; Madras, July 21-27, 10 deaths.

PLAGUE—INSULAR.

Honolulu: Hawaii, Aug. 30, 1 death.

PLAGUE—FOREIGN.

Arabia: Djeddah, July 16-22, 11 cases, 11 deaths.
Egypt: Alexandria, Aug. 4-9, 8 cases, 7 deaths; Suez, Aug. 3-9, 4 cases, 4 deaths.
India: General, July 7-14, 450 cases, 346 deaths; Bombay, July 24-Aug. 7, 69 deaths; Calcutta, July 14-28, 17 deaths; Karachi, July 22-Aug. 5, 16 cases, 16 deaths; Rangoon, July 14-28, 277 deaths.
Japan: Formosa, July 21-31, 20 cases, 29 deaths.

Society Proceedings

COMING MEETINGS.

American Electro-Therapeutic Association, Philadelphia, Sept. 18-20.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Sixteenth Annual Meeting, held at Salt Lake City, Utah, Aug. 30-Sept. 1, 1906.

The President, Dr. M. L. Harris, Chicago, in the Chair.

(*Continued from page 788.*)

Gastrointestinal Ulcer.

Dr. H. D. Niles, Salt Lake City, stated that ulcer is not only a producer of symptoms, as a primary lesion, but may be the antecedent of many grave complications and sequelæ; it might indirectly cause a great variety of puzzling symptoms, which the surgeon must try to interpret correctly. So long as physicians think of gastrointestinal ulcer simply as a theoretical possibility, of rare occurrence, and of obscure pathology, the symptomatic treatment will prevail, and unsatisfactory results will follow. As soon as physicians learn to appreciate that ulcer is not only a real pathologic entity, but that it is the most common of all gastrointestinal lesions, they will find them selves very near the true explanation of many obscure chronic abdominal symptoms, and will be prepared to formulate a timely and rational treatment for the pathology that produces these symptoms.

DISCUSSION.

Dr. Andrew C. Smith, Portland, Ore., said that gastrointestinal ulcer is a common pathological entity that should be considered in all conditions of chronicity of abdominal symptoms.

Dr. W. W. Grant, Denver, said that gastroenterostomy for ulceration of the stomach and intestine, particularly the duodenum, and for obstructive lesions of these parts, is now one of the most common and conservative of modern operations. Like most new surgical triumphs, it is likely to be abused somewhat before it reaches its proper status as a surgical procedure. Surgeons should be a little more conservative in the surgical treatment of these conditions, and not until there are manifest evidences of ulcer, such as persistent ulceration or obstruction is it desirable to perform this operation. A large number of these cases are attended with profuse acute hemorrhage. They are the chronic digestive cases, in many of which the hemorrhage is not manifested; but the investigations of Rosenthal and Frederick show that in these cases there is occult hemorrhage. This is shown chiefly by microscopic examination of the contents of the stomach and of the fecal discharges. When this condition exists and persists, operation is demanded. Operation, however, should not be undertaken until medical treatment and other non-surgical measures have been given reasonable trial.

Dr. B. B. Davis, Omaha, said that in a number of instances of ulcer of the stomach, duodenum, and in the region of the pylorus, he has been able to get a definite idea as to the location of the ulcer by distending the stomach, whereas before this he was absolutely at sea. Whenever there is suspicion of ulcer, either of the stomach, the duodenum, or intestinal tract lower down, the physician should resort to systematic daily examinations of the stools for blood. In a number of instances he has been able to arrive at a definite idea in this way, whereas, if he had resorted to gross inspection simply, he never would have suspected what existed.

Dr. John C. Morfit, St. Louis, said there was nothing that he admired more than radical conservatism. He liked to see a man who could use his head without using his knife, but who never used his knife without using his head. The greatest point of gastrointestinal ulcer is not the operation; it is the diagnosis. Gastroenterostomy has been so perfected that it is now a comparatively simple procedure, and for that reason men with surgical tendencies might operate sometimes because they could, and not because they ought to. He would hesitate to operate on a case of gastric ulcer until the patient was seen by a good internist and a good neurologist, on account of the elements of hysteria and neurasthenia being connected with the case.

Dr. E. F. Root, Salt Lake City, said it ought to be made plain to the general practitioner that ulceration of the bowel is very much more frequent than was previously supposed. General practitioners, men who were not doing very much surgery, are liable to have a very vague idea of what is going on within the abdomen. If gastrointestinal ulcer is diagnosed, it should be dealt with surgically as soon as possible.

Dr. R. C. Coffey, Portland, said that these ulcers are the seat of cancer in a very large proportion of cases. He has also learned that ulcer and cancer occur in the same location, usually, where the gastrointestinal contents are detained for some reason or other. A frequent seat for cancer is the cecum. Fecal matter is detained here for a while, then it is passed over until it reaches the sigmoid. Very rarely is cancer found at the splenic flexure, at the hepatic flexure, or in the transverse colon. The next frequent point for ulcer an cancer is the sigmoid; next the rectum.

Surgical Treatment of Splanchnoptosis.

Dr. B. B. Davis, Omaha, presented a brief statement of the anatomic changes found, and described the various surgical procedures which have been proposed and carried out for the relief of this condition. He gave a résumé of his own operations.

Late Phlebitis Following Clean Abdominal Operations.

Dr. W. W. Grant, Denver, presented that form of phlebiti culminating in the veins of the legs and which is known t occur most frequently about two weeks after simple, asepti abdominal operations, without being preceded by faster pulse elevation of temperature, pain or any indication at presen known of its advent. In the great majority of cases it culminates in the vessels of the left leg, no matter where the incision is made. He quoted at length from the literature, and showed that the etiology of this condition is still very hazy His belief is that the cause of phlebitis of the epigastric, iliac femoral, saphenous and tibial vessels, occurring late after a perfectly aseptic operation, and clean, prompt healing of the wound, is probably not septic. The specific cause is unknown In the absence of convincing or pathological evidence, and in the face of profound surgical skepticism, it is not rational in the best and cleanest days known to surgery to assume infection that was devoid of satisfactory evidence. It is exceedingly difficult, in fact quite impossible, to reconcile the facts with the recumbent position, the simple ligature, or injury to small veins, in a distant field on the opposite side of the body, although admitting that infection might not come from the site of operation. The author believes there is a general condition affecting the composition of the blood that might be caused before operation, which is an essential factor in the cause of *thrombo-phlebitis in these cases.* A careful scrutiny of patients should be made before operation and an examination of the blood made before and after operation. If the patient is chlorotic and anemic, or the conditions not satisfactory, the health should be improved, if delay is permissible, by the administration of iron and acids, and metabolism should be improved by a suitable food supply, while specific or constitutional affections should receive just consideration.

DISCUSSION.

Dr. A. C. Stokes, Omaha, said that there was referred to him an anemic, pale woman, 56 years of age, in whom beginning carcinoma of the rectum was suspected. She was given an anesthetic for the purpose of examination. A speculum was introduced well up into the rectum without producing any great amount of traumatism to the mucous membrane. After this the patient was returned to bed and kept there on account of her anemic condition. Four days later she developed phlebitis. He was unable to say whether the phlebitis was due to the traumatism of the rectum or to the anesthetic. He thought it was the anesthesia which produced a general toxemia in some cases, and this might produce in turn a chemical change in the blood, which at times might produce, in connection with rest in bed, venous stasis, etc. He is inclined to believe that the great majority of these cases are septic, and whenever he sees a case of phlebitis he always searches for a focus of infection.

Dr. Harry M. Sherman, San Francisco, cited one case of phlebitis of the left femoral vein and mentioned two others occurring in the practice of other surgeons, all three operations having been done by different men and each operation being different.

Dr. Leonard Freeman, Denver, pointed out that femoral phlebitis occurs in connection with appendicitis even when no operation is done. He has seen a double femoral phlebitis result in a case of appendicitis within a few days, with the patient not lying in bed. Phlebitis occurs in connection with other things where there is no question about septic infection. For instance, in an ordinary Pott's fracture of the right leg, and in one case of simple fracture, left femoral phlebitis resulted in the course of a week or two. In another case of fracture of the left patella a right femoral phlebitis developed and a left phlebitis afterward. These could not be explained by infection.

Dr. E. S. Wright, Salt Lake City, recalled his first case of phlebitis following an operation for appendicitis. The appendix had ruptured and had filled the pelvis with pus. He drained through the cul-de-sac and the vagina became partially obliterated. Possibly the traumatism incident to the first introduction of the speculum in this case contributed to the result. The patient recovered from the phlebitis without any particular treatment.

Dr. J. Clark Stewart, Minneapolis, said the general impression among pathologists is that thrombosis is in many instances of bacterial origin. The term sepsis is a *bête noir* for the surgeon, and naturally surgeons refuse to accept sepsis as a cause of anything in connection with what they are doing. If the term bacteriemia is used they would be, perhaps, more willing to accept it. It would seem that many cases, if not all, of thrombosis are due to bacteriemia. Pus bacteria enter the blood from unknown sources and give rise to such diseases as osteomyelitis. There is only one way to do, and that is to have blood cultures made of the cases that have femoral thrombosis and see whether or not they have bacteria in the blood. The presence of bacteria in the blood does not necessarily mean sepsis in a surgical sense, as a patient might have a certain number of bacteria circulating in the blood without clinical manifestations. It is only when some point of least resistance occurs that the lesions are localized.

DISCUSSION.

Dr. Andrew C. Smith, Portland, Ore., recalled three cases of phlebitis from three different types of operations in his own work. None of them was immediately septic, but each of them was remotely septic. He attributed each case to the catgut, and thought the slight sepsis present was due to late disintegration of the chromic catgut and the absorption of toxins from that.

Dr. Union Worthington, Salt Lake City, did not believe that trauma is a cause of phlebitis. Whenever he has a case of phlebitis it is his practice to look for infection. The fact that phlebitis more frequently occurs in the left leg than in the right has never been satisfactorily explained to him.

Dr. Grant expressed the belief that blood examinations by bacteriologists and pathologists would have to settle the question. Pathologists have not been given a good chance thus far because most of the patients recover; but the rather dogmatic statement of Murphy that recumbency is the cause is not a tenable one.

(*To be continued.*)

BRITISH MEDICAL ASSOCIATION.

Seventy-fourth Annual Meeting, held in Toronto, Ontario, Aug. 21-25, 1906.

(*Continued from page 800.*)

SECTION ON STATE MEDICINE.

This section, which met in the new science building and was presided over by Dr. Frederick Montizambert, Ottawa, Ontario, had a most attractive program, divided by days into symposia on "Tuberculosis," "Control of Water and Milk Supplies," "Hygiene of the Home and Public Institutions" and "International Sanitary Protection."

Problems of Water Supply.

Dr. Hibbert W. Hill, assistant director of the health laboratories, Minneapolis, prepared a paper on "Water Supplies from a Sanitary Standpoint," which was read in his absence by Dr. F. F. Wesbrook. He advised the continuous supervision of the water supply in order to forestall outbreaks of typhoid fever. He expressed the advice that in municipalities where large quantities of water were used filtration was the only practicable method of artificial purification. The English filter bed may be compared to a water-tight reservoir, suitably underdrained and filled to the depth of five or six feet with proper filtering material. The water flows evenly and slowly over the surface of the sand, leaving most of its suspended material on the top. The rate of filtration by this method of slow filtration averages from about two to two and a half million gallons per acre per day, and, of course, a large filter costs less in proportion than a small one. A filter one acre in extent would cost about $60,000. The essayist urged the repeated examination and treatment of water supplies which have been allowed to become polluted. In speaking of the purification of water he discussed the methods of filtration, distillation and aeration, giving special attention, as above stated, to the "slow sand" or English filter bed. In mechanical filtration a small quantity of some coagulant, preferably aluminium sulphate, is added to the sand before it reaches the water. The aluminium hydrate thus formed becomes a most important constituent of the filter; for without it its bacteriologic efficiency is very low. Water is then added to the filter, which is a tank or cylinder, three parts full, of a specially selected sand with a suitable underdrawing for carrying the filtered water to the reservoir. The sand becomes dirty in a short time, depending on the turbidity of the water, and must be washed by a reversed current at least once every day.

Water Purification.

Dr. Henry D. Holton, Burlington, Vt., secretary of the state board of health, in his paper on "Water Supplies" declared that the custom of discharging sewage into rivers and other bodies of water can not be too strongly condemned. This practice is a long-standing menace to all water supplies and will sooner or later be the cause of disaster to the health of the community using the water supply. He advocated the careful analysis of all sources of public water supply, and considered the filtration of water a necessary precaution and the filtration of sewage, by which a comparatively harmful effluent might be discharged, also necessary. He called attention to editorials on sewage disposal which he had seen since his arrival in Toronto, which could have been written only in ignorance of the dangers arising from the contamination of the water supply by sewage. He attributed a great proportion of the intestinal and kidney troubles from which the people suffer to a pollution of the water supply. Many interstate and international bodies of water have become affected by the prevalent custom which tends to pollution. The question of reservoirs itself is one that demands governmental attention. Filtration removes the odor and dangerous bacteria, but the tendency among the municipalities to overlook the importance of this feature of water supply is all too apparent.

Purification of Water Supply.

Dr. William J. Robinson, medical health officer of Guelph, Ontario, considered the artificial purification of water for human consumption. He discussed the effect of the sand filter, the rates of filtration and the questions of chemical and mechanical filtrates, and finally referred to the experience of several American cities in which the lowering of the death rate from typhoid fever had followed the adoption of filtering plants.

Prof. John Glaister, Glasgow, said that a water supply, pure and abundant, is the best line of defense against the epidemics which formerly swept communities. As a result of such care, he stated that there is now no such thing in Scotland as an epidemic due to impure water. Large reservoir accommodations and adequate sedimentation areas are needed for filtration, but the color can not be removed by filtration. In his experience there are three ways of securing a good, pure supply of water: First, the purchase outright of the gathering ground or watershed of the district of supply, or of the lake itself, as in the case of Manchester; second, as in the case of Glasgow, the purchase of the rights of conservation of the watershed with the object of preventing pollution, and, third, *an arrangement* whereby a municipality secures the right of inspection of its water supply.

Pollution of Canadian Streams.

T. A. **Starkey**, professor of hygiene in McGill University, Montreal, discussed the question of pollution of water supplies by sewage and gave a summary of his observations for a series of years of the gradual deterioration of the water in the Ottawa and St. Lawrence rivers. He expressed disbelief in the popular idea that large rivers completely purify themselves of pollution by sewage. From a bacteriologic point of view the so-called purification is merely dilution and the pollution is not disposed of. In the St. Lawrence River there has been a gradual increase from an average of 90 colonies of bacteria in 1903 to 168 in 1906. These figures are striking, showing that, whether from sewage or surface drainage, the waters of the river were becoming more polluted every year. The progress of pollution of the Ottawa River is more rapid, the average of increase in the colonies of bacteria having risen in the same period of time from 110 to 300 colonies, and on some special occasions in that part of the river from which Westmount obtains its water supply he found from 1,000 to 1,500 colonies of bacteria, and the average for the entire year was 600. However, a chemist would have been forced to pass this water as first class. Under modern conditions it is practically impossible to obtain a supply of pure water without filtration. He believes that the condition of Canadian waters is becoming dangerous and that the conditions which prevail in Winnipeg would in a very short time exist in the eastern cities unless radical measures are adopted.

Water Situation in Ontario.

Dr. Peter Henderson Bryce, Ottawa, formerly secretary of the board of health and now dominion officer of health, said that the question to be decided in Ontario was whether a fight was to be made against the pollution of streams or whether filtration was to be depended on. He is opposed to the pollution of streams. He described the methods adopted by the provincial boards of health for the disposal of sewage in Muskoka, by reason of which, with an average summer population of 20,000, there had not been as much typhoid fever in the last five years as there would ordinarily be found in a common rural community. He was gratified to be able to announce that in at least 125 towns in Ontario the water supply is now reasonably free from suspicion.

Control of Milk Supply.

Prof. R. Harcourt, Guelph, Ontario, contended that the milk is very rarely kept and handled under proper conditions and that the methods applied to the handling and bottling of milk are in almost every instance faulty. Milk should be used more extensively as a food and not regarded as a luxury. While a most valuable food, milk is especially susceptible to contamination, which it is almost impossible to prevent. Even the use of the milking machine, an improvement on the old method, has not been entirely successful in the elimination of contamination. If a commission were appointed to investigate the conditions under which the milk supply is handled and delivered to the consumer, the report would, he believed, be worse than that recently made regarding the packing establishments of the United States. The consumer has a right to demand milk which, if kept at a temperature of 60 degrees or less, will remain sweet for twenty-four hours. The advisability of the establishment of such a standard for milk, the price of which should depend on the quality of the article furnished, was considered. The addition of preservatives of any kind was deplored as injurious to the public health, and as, under some circumstances, deleterious to the food quality of the milk.

Prof. John Glaister, Glasgow, in his paper on "Administration and Control of Milk Supplies," detailed the methods whereby the purity of milk could be assured to the consumer and gave the result of the efforts to that end in Glasgow.

Prof. R. Tanner Hewlett, London, stated that one of the greatest difficulties in this matter is that public opinion has not been sufficiently aroused and that it is difficult to have legislation preceding public opinion. He emphasized the necessity of compulsory inspection of cattle, the eradication of bovine tuberculosis by approved scientific methods. He also spoke of the regulation to be applied in connection with the housing of cattle and the advisability of the adoption of more satisfactory mechanism for the enforcement of sanitary laws. The questions of temperature and the care of milk were declared to be very important, and the speaker believed that many of the containers now used are veritable microbe traps. He favored the use of sealed bottles for the distribution of milk, and further suggested as a preventive measure the immediate chilling of the milk.

A resolution was thereon adopted by the section that the section strongly recommend to the local government boards of Great Britain, Ireland and to the provincial board of health of Canada that the time has come when the existing provision of the law with regard to the housing of dairy cattle, milk storage and milk distribution and the periodic inspection of such cattle and dairies should be more strictly enforced.

(To be continued.)

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTO-LARYNGOLOGY.

Eleventh Annual Meeting, held at St. Clair, Mich., Aug. 30-Sept. 1, 1906.

The President, **Dr. Casey A. Wood**, Chicago, in the Chair.

The academy was called to order by the president, and an address of welcome on behalf of the state of Michigan was made by Congressman Edwin Denby, to which a suitable response was made by Dr. Charles B. Stockwell, Port Huron, Mich, president of the Michigan State Medical Society.

Addresses.

Dr. Casey A. Wood, Chicago, president, and **Dr. Joseph A. Stucky**, Lexington, Ky., vice-president, delivered a joint address on the "Relationship of the Eye to the Orbit and the Neighboring Cavities."

The oration on oto-laryngology was delivered by Dr. Dundas Grant, London, Eng., on "Some Practical Problems in Otology and Rhinology."

The oration on ophthalmology was delivered by Mr. R. Marcus Gunn, F.R.C.S., London, Eng., on "Optic Nerve Ailments."

Both these orations were illustrated by the stereopticon.

Election of Officers.

The following officers were elected: President, Dr. Joseph A. Stucky, Lexington, Ky.; vice-presidents, Drs. Richard A. Reeves, Toronto, and Eugene Smith, Detroit; secretary, Dr. George F. Suker, Chicago (re-elected); treasurer, Dr. Otto J. Stein, Chicago (re-elected), and members of the council, Drs. Joseph A. Stucky, Lexington, Ky., Hanau W. Loeb and Adolph Alt, St. Louis; Alvin A. Hubbell, Buffalo, N. Y., and William L. Ballenger, Chicago.

The academy will probably hold its 1907 session in Louisville, Ky., but the exact time and place will be fixed by the council about six months before the time for the meeting.

(To be continued.)

AMERICAN ORTHOPEDIC ASSOCIATION.

Twentieth Annual Meeting, held in Toronto, Canada, Aug. 20-22, 1906.

(Concluded from page 801.)

Congenital Dislocation of the Hip.

Dr. George B. Packard, Denver, reported cases and made remarks on the treatment by manipulative reduction. The most favorable time for reduction is shortly after the patient begins to walk. The hamstrings should be left unstretched, so that if redislocation occurs after application of the plaster this may be indicated by sudden relaxation of the hamstrings. In unstable cases especially the plaster should be applied very snugly.

Coxa Valga.

Dr. James K. Young, Philadelphia, reported several cases in which, as shown by skiagraphs, the angle between neck and shaft of femur seems to be wider than normal, i. e., more than 135°. Adduction of the thigh is limited.

DISCUSSION.

Dr. John Ridlon, Chicago, in discussion of the two foregoing papers, said that in congenital anterior dislocation of the hip reduction should be effected by inward rotation after flexion, Anterior dislocation is shown by feeling the head in the groin on extreme outward rotation. The angle between the neck and the shaft of the femur in a skiagraph can be increased by rotating the leg, and this probably accounts for the apparent cases of coxa valga reported.

Dr. Albert H. Freiberg, Cincinnati, said that great caution was necessary in estimating the angle of the neck from a skiagraph.

Dr. Young said that he believed that at least three of the cases presented by him were coxa valga.

Plaster-of-Paris.

Dr. Walter G. Stern, Cleveland, said that the greatest strength is obtained from slow-setting dental plaster that requires from 6 to 7 minutes to set. All agents that hasten the time of setting weaken the result. From 10 to 20 per cent. Portland cement in the plaster strengthens the result without lengthening the time of setting. The mixed plaster and cement can be softened by immersion in water for half an hour so that it can be cut by a sharp knife.

Intermittent Limping.

Dr. Robert W. Lovett, Boston, said that early symptoms simulate those of simple static foot trouble. The trouble is primarily circulatory and the only effective treatment of it is rest. He recorded three cases, one of which came to amputation.

DISCUSSION.

Dr. Albert H. Freiberg, Cincinnati, said that cases of foot trouble which are not relieved by rest are probably only secondarily static and should suggest arteriosclerosis.

Dr. Joel E. Goldthwait said that the regularity of onset of symptoms, as always after walking two blocks, suggested arterial trouble. Great and sudden pain is also suggestive.

Dr. Lovett said that in every case of foot trouble that he saw he palpated the dorsalis pedis and the posterior tibial arteries in order to rule out circulatory trouble.

Dr. Compton Riely, Baltimore, read a paper entitled "Report of a Case of Chronic Dislocation of the Lower Jaw, Presenting a Simple Device for Maintaining Reduction."

Old Fractures of the Tarsus.

Dr. Leonard W. Ely, New York, reported seventeen cases. He said that in cases of chronic foot trouble an old fracture is often unrecognized. Treatment of old cases should be symptomatic, as by supportive adhesive strapping; but treatment is unsatisfactory. Recent cases of foot trauma should be skiagraphed to discover fracture if present. Recent fractures of the tarsus should be immobilized; displaced fragments should be dealt with surgically.

DISCUSSION.

Dr. Charles F. Painter, Boston, said that prolonged immobilization of old cases in plaster-of-Paris is the only effective treatment. Operative treatment in old cases is usually to be avoided.

Dr. Frank E. Peckham, Providence, R. I., reported an old case in which removal of a fracture spicule entirely relieved the symptoms.

Supports for the Arch.

Dr. Phil. Hoffman, St. Louis, read a paper entitled "A Method for Measuring for Shaping and Placing Cork, Felt, Leather or Similar Arch Supports." A paper model is cut out to cover area of sole enclosed between marks at posterior margin of ball of great toe, anterior margin of weight-bearing surface of heel and ¾ inches from outer margin of sole. The astragaloscaphoid juncture is marked on the paper as the highest point of the support, and the support made from this model is set in the shoe so that the highest point is as far from the back of the shoe as the astragaloscaphoid juncture is from the back of the heel.

Dr. Ansel G. Cook, Hartford, Conn., read a paper entitled "A New Form of Shoemaker's Last." The foot is placed on a steel plate shaped like the sole of a shoe, and foot and plate swathed in plaster-of-Paris. This is cut off and filled with plaster. The shoe is made directly on the resultant cast, without hammering. The cast can be changed by the surgeon to any shape desired.

Suture Necrosis in Tendon Suture and Tendon Transplantation.

Dr. David Silon, Pittsburg, reported having made an experimental study of the influence of such necroses. The research leads to the conclusions that the strength in the union of grafted tendons depends on the callus; that failure to hold from necrosis must be very rare; that failure to hold on account of insufficient suturing is probably common. Tendons should be raised from their sheaths as little as possible, and sheaths should be restored by suturing the divided edges.

Torticollis.

Dr. Reginald Sayre, New York, said that many cases of torticollis, formerly supposed to be due to "cold" or "rheumatism" in the soft parts, are probably dependent on arthritis of the cervical spine, or to slight fracture. He reported cases.

Drs Robert W. Lovett, Boston, and S. C. Baldwin, Salt Lake City reported cases.

Hemophilic Joints.

Dr. Arthur J. Gillette, St. Paul, reported that subcutaneous injection of 5 per cent. gelatin solution in one case several times stopped dangerous hemorrhage into joints. Great destruction of joint may be caused, thus simulating joint tuberculosis. Rise in temperature precedes hemorrhage into joints. Immobilization and ice application relieves the severe joint pain. Gelatin by mouth is sometimes prophylactic.

DISCUSSION.

Dr. Edwin W. Ryerson, Chicago, reported a hemophilic joint that had been mistaken for a gonorrheal joint.

Dr. Joel E. Goldthwait, Boston, said that in one case 5 grains salicylate of sodium, twice in day, always greatly relieved the pain of an attack.

Dr. Gillette said that he believed that so-called purpuric rheumatism was really hemophilic joint.

Wednesday morning, August 22, the Association visited the Toronto Orthopedic Hospital, where a clinic was conducted by Dr. MacKenzie, and a luncheon given by the ladies' board of the hospital. Apparatus was exhibited and cases reported by Drs. David Silon, Pittsburg; Herbert P. H. Galloway, Winnipeg, Canada; Ansel G. Cook, Hartford, Conn.; Compton Riely, Baltimore; Wm. E. Blodgett, Detroit; Bart E. MacKenzie, Toronto; Walter G. Stern, Cleveland; Edwin W. Ryerson, Chicago, and J. T. Watkins, San Francisco.

AMERICAN ROENTGEN RAY SOCIETY.

Seventh Annual Meeting, held at Niagara Falls, N. Y., Aug. 29-31, 1906.

(Concluded from page 798.)

(Concluded from page 798.)

Teaching Roentgenology in Medical Colleges.

Dr. Vernon J. Willey, Ann Arbor, Mich., urged that medical colleges should give some attention to the teaching of Roentgenology, because of its value in diagnosis and therapeutics. Instruction should be given in the principles rather than in the technic, which must be acquired by actual experience. An intelligent grasp of the principles of Roentgenology involves a knowledge of radiophysics, a general knowledge of the apparatus employed, of radiography and fluoroscopy, with especial reference to the interpretation of screen and negative;

of radiotherapy, with especial reference to pathologic conditions which yield to irradiation. Students should be taught the effects of the rays on various tissues, and the limitation of the ray in therapeutics. A course of twelve or twenty hours is sufficient.

Method of Estimating X-Ray Dosage.

Dr. **Henry G. Piffard**, New York City, takes a brass ball about one and one-quarter inches in diameter and supports it about four inches from the wall of the tube just within the circle of rays issuing from the anterior hemisphere. The ball is then connected by a cord about eight feet long to the charging device of the electroscope. As soon as the current passes through the tube the aluminum needle or foil indicates the charge and the angle is easily read off on the scale. For this purpose he found Braun's electroscope, which is graduated in volts, or his own, which is graduated in degrees of an arc, very convenient. The angle varies directly with the current passing through the tube, and also shows whether the tube is running steadily or not, and indicates any notable change in the vacuum.

Roentgen Ray Filter.

Drs. **G. E. Pfahler** and **J. F. Schamberg**, Philadelphia, conducted a series of experiments on rabbits in which use was made of silver, leather and aluminum, for the purpose of establishing their value as filters. They found the leather of decided value for filtering out the soft, medium and hard rays. They also found that the susceptibility to the rays varied in animals, which doubtless is also true of man.

New Direct Reading of X-Ray Meter.

Dr. **George C. Johnston**, Pittsburg, takes advantage of the fluorescence produced on a tungstate of calcium or other screen as indicating the quantity of the *x*-rays emitted. The fluorescing screen is placed in a light, tight box, and facing it is a selenium cell, which has the property of changing its ohmic resistance to the passage of the electric currents with relation to the presence or absence of light waves. Such a cell, when kept in total darkness, may have the resistance of several hundred ohms, yet on permitting light, natural or artificial, to strike on the cell, its ohmic resistance falls almost instantly to a great degree, and this alteration bears a direct relation to the intensity of the light. If there is placed in series with such a cell a galvanometer or ammeter of sufficient delicacy, a series of current such as an ordinary dry battery and a variable rheostat providing a means of introducing more or less ohmic resistance into the circuit, and the rheostat, the measuring instrument, and the selenium cell be balanced, the point will be found at which the ohmic resistance of the rheostat, the communicating wires, the selenium cell, and the measuring instrument will exactly balance the electromotive force of the battery.

If, however, the container having within it the screen and cell be placed in the path of the *x*-rays, the screen will become luminous in proportion to the distance from the source of the rays and the quality of rays striking it. The container will be illuminated, the selenium cell under the influence of this light will change its ohmic resistance in proportion to the light, and the current flow will be measured and indicated on the dial of the galvanometer or other instrument employed for the purpose of making these electric measurements.

President's Address.

Dr. **Henry Hulst**, Grand Rapids, Mich., presented further observations on the "Roentgenology of the Stomach and Intestines," and illustrated his paper with a large number of instructive radiographs.

Treatment of Lupus Vulgaris.

Dr. **H. W. Van Allen**, Springfield, Mass., reported 15 cases, with 80 per cent. cures. The average time since treatment was discontinued is from one year to eight months. The average time of treatment is six months, the shortest period being three months and the longest nine months. The most recent case was treated three months ago. The longest time that has elapsed since treatment is three years. Eleven cases were cured; in one there was an apparent cure; one is returning, and two cases were not benefited.

Tubercular Adenitis.

Dr. **Russell H. Boggs**, Pittsburg, said that the results obtained by the Roentgen ray in the treatment of tubercular adenitis compare favorably with those obtained by any other method. A large proportion of the cases can be apparently if not permanently cured. Several cases have remained cured for over four years. Improvement is not obtained, as a rule, until at least twelve treatments have been given. There are exceptions, however, one patient being improved after four treatments, and others not improving until after twenty-five or more treatments. A permanent cure should not be expected until after at least three months' treatment. He advised that in treating these cases the apices of the lungs should also be rayed. To be beneficial treatment must be energetic.

Ultimate Results in Carcinoma of Breast.

Dr. **George C. Johnston**, Pittsburg, advised treatment of all cases of carcinoma of the breast, both before and after operation. The application of the *x*-ray combined with skillful surgery offers the only hope of cure. Postoperative treatment should be begun not later than the tenth day. The mediastinum and axilla should also be rayed. Primary carcinoma should be treated by the ray alone only when the age and condition of the patient argue against operation. Mediastinal involvement is not a sign of fatality. No case should be treated with the *x*-ray that can not be treated surgically. Filters should always be used.

Measurement of Diameter of Pelvis.

Dr. **George E. Pfahler**, Philadelphia, described his method of measuring the diameter of the pelvis by means of the Roentgen ray. The technic is based on four principles: 1. The plate must be brought parallel to the brim of the true pelvis. 2. Measure the distance of the brim of the pelvis from the anode of the tube. 3. Distance of anode of tube from plate. 4. To place the anode in the axis of the brim of the true pelvis. To assist in attaining successful results he makes use of a very simple apparatus, which was exhibited.

Roentgen Ray in Dermatology.

Dr. **Andrew P. Biddle**, Detroit, said that experience has shown the value of the Roentgen ray in the treatment of skin affections when it is used conservatively and with due regard to recognized dangers. The ray is useful in selected cases, but not as a routine treatment. It should be used in addition to other remedies, especially in those cases which have resisted ordinary treatment and where there is a marked infiltration of tissue. Stubborn cases of acne, otherwise incurable, yield readily to the ray and relapses are less frequent. The *x*-ray is contraindicated in all acute cases and in the acute exacerbations of all chronic cases.

Treatment of Epithelioma.

Dr. **Kennon Dunham**, Cincinnati, said that in epithelioma of the face, except when the tumor is situated on the lip, the *x*-ray gives the best results in every way. That the *x*-rays have scattered the growth throughout the body, doing more harm than good, is true, but that is due to the fact that physicians generally use any tube in place of securing the most suitable tube. In cases of tumor of the lip a radical operation should be done, with careful dissection of all lymphatics draining the part. Radiation before and after operation (for at least two months) is essential. After operation exposures can be made every second or third day, using a leather filter. In cases of recurrent rodent ulcer and large epitheliomata of the body or extremities which have penetrated deeply he uses the galvanic current, with local or general anesthesia, completely surrounding the tumor with galvanized needles, connecting these with the positive pole of the battery, using 30 to 110 volts. This closes the lymphatics and blood vessels surrounding the tumor, lessening the danger of metastasis and a large part of the tumor sloughs out. His results have been excellent.

Diagnosis of Renal Calculi.

Dr. **F. H. Baetjer**, Baltimore, said that with a good apparatus and technic calculi, when present, can practically always be found. The position of the calculus should be determined positively, so that the surgeon, when operating, can not overlook the stone. The use of the x-ray for this purpose is free from danger and of great benefit to the patient. Negative findings should not be relied on.

Diaphragm in Roentgenography of Chest.

Dr. P. M. Hickey, Detroit, said that a small negative made with the diaphragm shows more detail of structure than a large general plate. Early changes in the lung are easily shown with a diaphragm plate, and it is more accurate in detecting small areas of involvement than is the stethoscope. Diagnoses can also be made earlier.

Roentgen Ray in Blood Diseases.

Dr. Henry K. Pancoast, Philadelphia, reported the final results in cases referred to in previous papers, and added three new cases. He said that in leukemia the x-ray is not a curative agent, but by secondarily destroying excessive and abnormal kinds of lymph tissue, and by greatly increasing the numbers of leucocytes in the blood, the individual organism is given a chance to remove the cause of the disease. In certain constitutional disorders the x-ray is not only dangerous, but may contribute to a fatal issue. One of the cases which last year he reported symptomatically cured had two relapses since, and the patient died. Another case reported as symptomatically cured has relapsed.

Changes in Kidneys Produced by Roentgen Ray.

Dr. A. S. Warthin, Ann Arbor, Mich., examined the kidneys of three cases in leukemia treated by the Roentgen ray. He found extensive necrosis and calcification, the changes in general resembling those produced by certain posions. He believes that long exposures damage the renal cells primarily to but a slight degree, but that after long irradiation there is a second injury to the kidney epithelium, due most probably to an intoxication. The destruction of the lymphoid tissue is the most probable source of the poison, the symptoms of the intoxication in general resembling those due to products of proteid distintegration.

Localization of Foreign Bodies in Eye.

Dr. Charles F. Bowen, Columbus, Ohio, has devised an apparatus for locating accurately foreign bodies in the eye. It is a modification of Sweet's apparatus, and can be used in conjunction with the compression cylinder diaphragm. It is so arranged that the patient's head is held absolutely quiet during the exposure. The plates are changed by means of a plate-holder without disturbing the head.

Carcinoma of Bladder.

Dr. Alfred L. Gray, Richmond, Va., reported a case of squamous cell carcinoma of the bladder in which the tumor was removed surgically, the pedicle being treated with the x-ray. Treatment was administered every other day, and after twenty-one treatments the stump of the tumor had disappeared entirely, leaving a soft linear scar.

Fee Table.

The committee appointed to prepare a fee table reported as follows: For work done in the laboratory: Sinus examinations, $25 to $50; location of foreign bodies in the eye, $25 to $50; examination of teeth, $10 to $75; diagnosis of renal and vesical calculi and gallstones, $50 to $200; examination of stomach and bowel, $75 to $200; examination of chest, $25 to $100; examinations of shoulder, $25 to $50; examination of elbow, $15 to $50; knee and wrist, $15 to $50; hip and pelvis, $50 to $150; foot and ankle, $15 to $50; leg and knee, $25 to $75; for work done outside of the laboratory, from 50 to 500 per cent. additional, according to mileage. The report was adopted.

The following papers were also read: "Further Experimental Research Concerning Direct, Indirect and Secondary Skiagraphic Rays," by Dr. L. G. Cole, New York City; "The Induction Coil," by Mr. H. C. Snoop, Philadelphia; "Résumé of the Radiometric Dosage of Roentgen Ray Therapy," by Dr. M. A. Kassabian, Philadelphia; "Use of X-Ray Filters in Radiotherapeutics," by Dr. Reginald Morton, London, Eng.; "The Tube in Roentgen Therapeutics," by Dr. E. G. Williams, Richmond, Va.; "Possibilities of Formulating a Standard of Radioactivity," by Dr. C. D. S. Phillips, London, Eng.; "Roentgenologic Study of Certain Manifestations of Syphilis," by Dr. Percy Brown, Boston; "Action of the Roentgen Rays on the Central Nervous System," by Dr. Carlo Colombo, Rome, Italy; "Differential Diagnosis of the Chronic Non-tubercular Joint Diseases by Means of the Roentgen Ray," by Dr. Robert B. Osgood, Boston; "Skiagraphy of the Accessory Sinuses of the Nose," by Dr. E. W. Caldwell, New York City; "General Observations as to the Effects of the X-Rays on Hair and Other Tissue Elements," by Dr. W. S. Newcomet, Philadelphia.

State Boards of Registration

COMING EXAMINATIONS.

Oklahoma Board of Medical Examiners, Guthrie, September 25. Secretary, J. W. Baker, Enid.

New York Boards of Medical Examiners, Albany, September 25-28. Chief of Examining Division, Charles F. Wheelock, Albany.

Utah State Board of Medical Examiners, Salt Lake City, October 1. Secretary, R. W. Fisher, Salt Lake City.

Arizona Board of Medical Examiners, Phoenix, October 1-2. Secretary, Ancil Martin, Phoenix.

Colorado State Board of Medical Examiners, Denver, October 2. Secretary, S. D. Van Meter, Denver.

Idaho State Board of Medical Examiners, Lewiston, October 2. Secretary, J. L. Conant, Jr., Genesee.

Montana Board of Medical Examiners, Senate Chamber, The Capitol, Helena, October 2. Secretary, Wm. C. Riddell, Helena.

Minnesota State Board of Medical Examiners, Old Capitol Building, St. Paul, October 2-4. Secretary, W. S. Fullerton, St. Paul.

North Dakota State Board of Medical Examiners, Grand Forks, October 2-4. Secretary, H. M. Wheeler, Grand Forks.

Rhode Island State Board of Health, Room 313, State House, Providence, October 4-5. Secretary, Gardner T. Swarts, Providence.

Georgia Board of Medical Examiners (Regular), Capitol, Atlanta, October 9. Secretary, E. R. Anthony, Griffin.

Arkansas State Medical Examining Board, Little Rock, October 9. Secretary, J. P. Runyan, Little Rock.

Kansas State Board of Medical Registration and Examination, State House, Topeka, October 9. Secretary, F. P. Hatfield, Grenola.

Michigan State Board of Registration in Medicine, Lansing, October 9. Secretary, B. D. Harison, Detroit.

Mississippi State Board of Health, The Capitol, October 9. Secretary, J. F. Hunter, Jackson.

District of Columbia Board of Medical Supervisors, Washington, October 11. Secretary, Geo. C. Ober, Washington.

New Jersey State Board of Medical Examiners, Trenton, October 16-17. Secretary, J. W. Bennett, Long Branch.

Texas State Board of Medical Examiners, Houston, October 16-18. Secretary, T. T. Jackson, San Antonia.

Florida Board of Medical Examiners (Regular), Jacksonville, October 17-18. Secretary, J. D. Fernandez, Jacksonville.

Illinois State Board of Health, Great Northern Hotel, Chicago, October 17-19. Secretary, J. A. Egan, Springfield.

Louisiana State Board of Medical Examiners, New Orleans, October 19-20. Secretary, F. A. Larue, New Orleans.

Indiana Board of Medical Registration and Examination, Indianapolis, October 23-25. Secretary, W. T. Gott, Indianapolis.

Kansas June Report.—Dr. F. P. Hatfield, Secretary of the Kansas State Board of Medical Registration and Examination, reports the written examination held at Kansas City, June 12-13, 1906. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 82, all of whom passed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Hahnemann Med. Coll., Chicago	(1905)	84
University of Kansas (1906) the grade of 75 was reached by one, 76 and 77 by two each, 78 by one, 79 by three, 80 by two, 81 by five, 82 by four, 83 by seven, 84 by six, 85 by five, 86 by four, 87 by three, 88 by one, 89 by two, and 90 by one; total, 47.		
Kentucky School of Med.	(1895)	78
St. Louis Univ. (Marion-Sims-Beaumont Med. Coll.)	(1906	83, 84
Washington University	(1906)	83
Barnes Med. Coll.	(1904) 80; (1906) 75, 79,	82
Homeopathic Med. Coll. of Missouri	(1895)	85
Kansas City Hahnemann Med. Coll.	(1905)	86
Eclectic Med. University	(1906) 79, 80,	80
University Med. Coll. of Kansas City (1906) 78, 78, 80, 80, 84,		84
Ensworth Central Med. Coll. (1905) 77; (1906) 75, 75, 75, 76, 76, 79, 80, 80, 82.		
Eclectic Med. Institute, Cincinnati	(1906)	83
University of Nashville	(1906)	78
Meharry Med. Coll.	(1906)	84

The following questions were asked:

EYE, EAR, NOSE, THROAT AND MEDICAL JURISPRUDENCE.

1. (a) How would you detect a foreign body in front of the lens? (b) behind the lens? 2. Give differential diagnosis of acute iritis and keratitis and give treatment of each. 3. Give etiology, pathology and treatment of acute otitis media purulenta. 4. Give symptoms, pathology and treatment of chronic otitis media. 5. Give diagnosis, symptoms and treatment of pharyngeal abscess. 6. Give treatment for the removal of foreign bodies lodged in the trachea or bronchus. 7. Give the positive signs of death previous to onset of rigor mortis. 8. Describe the patholoogy of a burn before and after death.

ECLECTIC MATERIA MEDICA.

1. (a) What are antiseptics? (b) Name five and give indications for their use. 2. Give botanical name and description of phytolacca, dose and indication for its use. 3. Give specific indications for the use of bryonia. 4. Name three drugs that have an action on the heart and give the indication for each one's use. 5. In what condition would you use apocynum? 6. Give the specific indications for the use of baptisia, sulphite of soda and colocynth. 7. In what conditions of skin and tongue would you give nux vomica? 8. In what pathologic conditions of the body would you give cathartics? 9. (a) What are emetics? (b) Name and classify three remedies used as emetics. 10. Give specific indications for the use of rhus tox., pulsatilla, lycopus and quinin.

ECLECTIC THEORY AND PRACTICE.

1. Describe and treat a case of cholera infantum. 2. What is specific medication? 3. What is meant by (a) excess, (b) defect and (c) perversion? (d) What are their effects on health? 4. Name four remedies that act specifically on the (a) respiratory organs, (b) digestive organs, (c) urinary organs and (d) the reproductive organs. 5. Give the special indications for (a) phytolacca, (b) apocynum, (c) eryngium, (d) nux vomica, (e) viburnum, (f) ergot. 6. Name five remedies used in sepsis. 7. Do you recommend the use of poultices? If so, why? 8. (a) Name the remedies usually indicated in typhoid fever; (b) scarlet fever. 9. How are remedies best prescribed? Why? 10. Treat a case of constitutional syphilis.

HOMEOPATHIC MATERIA MEDICA.

1. Give five prominent indications for sulphur. 2. Give five characteristics common to both bryonia and sanguinaria. 3. Name five leading remedies for typhoid fever and give three characteristic symptoms of each. 4. In beginning treatment of a chronic disease in which the patient has been previously overdrugged, what two remedies are usually recommended? 5. Give five characteristic indications for echinacea. 6. Write what you know of cratageus oxycanthe. 7. Differentiate between camphor and veratrum alb. in cholera. 8. Is the law of similars the only true law of curing disease? 9. Differentiate between mercury and kaliiod. in the treatment of syphilis. 10. Differentiate bladder symptoms of cantharides, terebintha and cannabis sativa.

HOMEOPATHIC THEORY AND PRACTICE.

1. Make a diagram of the chest and locate the valves of the heart thereon, on the surface. 2. Give differential diagnosis between gastralgia, gastric ulcer and duodenal ulcer. 3. Give symptoms and diagnosis of cirrhosis of the liver. 4. Give methods of diagnosis and symptoms in epidemic cerebrospinal meningitis. 5. Give diagnosis and treatment of herpes zoster. 6. Give differential diagnosis of renal and hepatic calculi and acute peritonitis. 7. Describe minutely typhoid fever in its different stages. 8. Name the abnormal heart sounds and points of intensity. 9. Give diagnosis and treatment of acute and chronic hepatitis. 10. Give differential diagnosis between acute yellow atrophy and sclerosis and hepatic cancer.

OBSTETRICS AND GYNECOLOGY.

1. Write two pages on diseases of pregnancy. 2. Face presentation—diagnosis and classification. 3. Cause of prolonged labor, and when is instrumental interference imperative? 4. Cause of pelvic deformity. 5 Placenta prævia—diagnosis and treatment. 6. Puerperal septicemia—history of the disease. 7. Puerperal insanity—classify and give prognosis. 8. Give indications for use of forceps. 9. Give four deformities of the pelvis. How would you detect them? 10. How would you treat fibroid tumor of the uterus?

PATHOLOGY.

1. Give the pathologic conditions of acute and chronic systitis. 2. Give the pathology of mitral stenosis. 3. Give the pathologic differences between chancre and chancroid. 4. Give the pathology of chronic parenchematous nephritis. 5. Give the pathology of amyloid liver and hepatic cancer. 6. Give the etiology and pathology of arterial sclerosis. 7. Give the etiology and pathology of multiple neuritis. 8. Give the etiology and pathology of pulmonary tuberculosis. 9. Give the etiology and pathologic condition in pachymeningitis spinalis. 10. Write two pages on the pathologic condition found in the different stages of acute croupous pneumonia.

CHEMISTRY AND TOXICOLOGY.

1. How is the specific gravity of a body heavier than water determined? 2. How are the decimal multiples of a gram designated? 3. What is electromotive force? 4. If a glowing charcoal ember is immersed in a jar containing oxygen, what takes place and what the result? 5. What is the treatment of acute poisoning by free iodin? 6. What are the chemical properties of HNO_3? 7. What is the treatment of poisoning by HCY? 8. In what quantities is NaCl, or chlorids represented by it, eliminated from a healthy person in twenty-four hours? 9. What is the treatment of chronic plumbism? 10. Give the principal tests for sugar in urine.

ANATOMY.

1. Describe the sphenomaxillary fossa, giving its boundaries. 2. Trace a blood corpuscle from the heart to end of great toe and return. 3 Which are the peculiar vertebræ (dorsal), and give peculiarities of each. 4. Bound Scarpa's triangle and name the various recognized triangles of the body 5. Describe the changes in the vascular system at birth. 6. Describe the lungs and give their histology. 7. Name structures divided in amputation of the thigh at the middle third. 8. Give the histology of the skin and name its appendages. 9. Describe the thymus gland, giving its minute anatomy and peculiarities. 10. Give the histology of the mammary glands.

SURGERY.

1. (a) Describe the operation for strangulated femoral hernia. (b) Including preparation of the patient. (c) Technic of the operation and the after treatment of the patient. 2. Give the differential diagnosis between malignant and non-malignant tumors. 3. Give treatment for a sprained ankle and name the tissues involved. 4. (a) Give the differential diagnosis between three varieties of hip-joint dislocations. (b) Give method of reducing each. 5. Give minute description of Chopart's operation. 6. Name the different varieties of talipes and give treatment of the last you name. 7. Describe minutely the ligation of the subclavian artery in its most accessible portion. 8. In gunshot wounds, what are the chief indications for operative treatment? 9. Name the different varieties of dislocation of shoulder joint and minutely describe reduction and treatment of any one of them. 10. (a) Give cause, diagnosis and treatment of tetanus. (b) How would you prevent it?

BACTERIOLOGY.

1. (a) Describe minutely and name the micro-organisms that produce cerebrospinal meningitis. (b) What bacterium does it closely resemble? (c) What three micro-organisms are usually associated in cerebrospinal meningitis? 2. (a) Differentiate parasites from saprophytes. (b) What are their functions? (c) What do they depend on for existence? 3. (a) Give general characteristics of *Bacillus tuberculosis*. (b) How would you stain the bacillus in sputum? (c) Name the most frequent channels of infection. (d) Name three bacilli that closely resemble the tubercle bacillus. 4. (a) Describe and name the micro-organism found in relapsing fever. (b) Are they ever found in any other disease? 5. (a) What are aërobis, anaërobics and faculative anaerobics? (b) Give examples of each bacteria. 6. (a) Give simple method of staining bacteria; (b) of staining bacteria in tissues. (c) Give Gram's method of staining. 7. (a) Give general characteristics of *Bacillus diphtheriæ*. (b) What bacteria are usually associated with diphtheria bacillus? (c) Give the difference between pseudodiphtheria bacillus and diphtheria bacillus. 8. (a) Describe the *Bacillus typhosus*.. (b) Give some of the common methods of infection from the bacillus of typhoid.. (c) Give the best methods of prophylaxis against typhoid fever. 9. What pyogenic organism produces pyemia? 10. (a) What is phagocytosis? (b) What is the difference between contagion and infection?

PHYSIOLOGY.

1. How is physiology studied? 2. Describe the main features of the circulation. 3. (a) Name the divisions of the vasomotor system. (b) From what part are the fibers of each known to arise? 4. (a) Name the fluids of the alimentary canal. (b) Where is the succus entericus found? 5. What conditions produce variations in the normal temperature? 6. Name the structures necessary for the formation of a reflex arc. 7. What three forces are in action in the absorption of digested food? 8. In what organs is the blood changed? 9. Give the symptoms of insufficient oxygen in the blood. 10. Mention three inorganic substances found in the body and state in what part each is found.

HYGIENE.

1. What are the most common sources of infection in diphtheria? 2. What means should be employed by persons prone to "catch cold"? 3. Does change in climate require any change in food? If so, what? 4. State the physical condition that makes the practice of taking hot baths inadvisable. 5. What constitutes hard and soft water? 6. What instructions as to hygiene should be given in a case of diphtheria? 7. Does alcohol possess a food action? 8. State the best means of disinfecting sputum. 9. What is meant by natural and acquired immunity from disease? Give an example of each. 10. What are the general effects of breathing impure air?

New Jersey June Report.—Dr. J. W. Bennett, Secretary of the New Jersey State Board of Medical Examiners, reports the written examination held at Trenton, June 19-20, 1906. The number of subjects examined in was 14; total number of questions asked, 135, from which candidate was required to answer 90; percentage required to pass, 75. The total number of candidates examined was 56, of whom 53 passed and 3 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Treatment of Chlorosis.

For the successful treatment of this condition five methods should be adopted: 1, Dietetic; 2, hygienic; 3, medicinal; 4, non-medicinal; 5, mental.

DIETETIC.

The food should be light and nutritious and capable of easy digestion and ready absorption. At first a small or moderate quantity should be given. Milk is one of the most useful foods when it is easily digested, but it fails in two ways of being a perfect food; it contains too little iron and large quantities must be taken to satisfy the patient.

A cupful of peptonized milk 3 or 4 times a day will be useful when unprepared milk disagrees. A good substitute milk is a mixture of equal parts of cream and hot water oz. of each), to which a little sodium bicarbonate and a teaspoonful of brandy may be added. All forms of animal food, prepared in a manner easy of digestion, are beneficial. G. Sée recommends scraped raw beef, as much even as 14 oz. a day. Raw, scraped, or powdered meat may be given in consommé, in the form of sandwiches, or mixed with chocolate or Burgundy and water. The digestive power for this kind of food must be carefully watched, and if necessary, aided by the addition of some appropriate digestive ferment. Eggs in any form are valuable, as they are generally rich in iron and easily digested.

Animal albuminates should predominate in the diet at first. Easily digested fat, such as butter, cream, broiled fat bacon, cod-liver oil, should not be added. Green, fresh vegetables, especially in the form of purées are useful, not only as food, but to obviate the tendency to constipation.

HYGIENIC.

At the outset rest in bed in a well ventilated room or on a couch in fresh air should be particularly enforced. In chlorosis the cardiac muscle undergoes fatty changes, and if the heart wall is to recover itself and perform its function normally afterwards, it must have as much rest as possible during the treatment. For some time the patient should not be allowed to rise before midday. As soon as some improvement in the blood condition is observable, and some return of healthy functional activity is apparent, a moderate amount of gentle out-of-door exercise may be permitted, and this should be gradually increased with each increasing gain in health and strength.

Rectify such disadvantages of the life of the patient as can be ascertained. Over-pressure at school, unwholesome conditions of work or amusement, late hours, worry, any emotional strain or excitement, sexual aberrations, tight lacing, etc., are points to which the physician's attention will be directed.

MEDICINAL.

Free elimination by the bowels, kidneys and skin must be maintained. Autotoxemia is a very frequent cause of chlorosis. A saline laxative given every morning is usually of great value.

In many cases the laxative iron mixtures are to be preferred. The following are excellent prescriptions:

R.	Tinct. ferri chloridi	m. x		60
	Magnesii sulphatis	gr. xx	1	20
	Sodii sulphatis	gr. xx	1	20
	Glycerini	ʒss	2	
	Infusi quassiæ, ad	℥i	30	

M. Ft. mist. Sig.: Two tablespoonfuls to be taken three times daily after meals.

If gastric symptoms are prominent, the following may agree with the patient better:

℞.	Ferri sulphatis	gr. iv		24
	Sodii bicarbonatis	gr. x		60
	Sodii sulphatis	ʒi	4	
	Tinct. zingib	m. xx	1	20
	Spiritus chloroformi	m. viii		48
	Infusi quassiæ, ad	℥i	30	

M. Ft. mist. Sig.: Two tablespoonfuls to be taken twice daily after meals.

Iron in some form is almost invariably indicated, yet it is well to remember that an alterative, arsenic, copper or mercury, will sometimes act much better than iron alone. It is surprising how rapidly many chlorotic patients improve on alterative treatment, even when there is no evidence whatever of specific disease. Arsenite of copper in doses of 1/100 gr. two or three times a day after meals, or the specific tincture of copper of the eclectics in doses of 3 to 6 minims will prove very efficacious. Fowler's solution (m. v to x) in water after eating; small doses of arsenous acid (1/100 to 1/60 gr.), or the solution of arsenic and mercuric iodid (5 to 10 minims), are all valuable in anemic conditions. Indeed, inunctions of a very small amount of mercurial ointment once a day, or every other day, or small doses of mercuric chlorid, from 1/60 gr. to 1/40 gr., are often of decided benefit in chlorosis.

Nearly every form of iron has been employed, the preference seeming to be for Blaud's mass.

The *following prescriptions* are all *good:*

℞.	Ferri et potassii tartratis			
	Liq. potassii arsenitis, āā	ʒi	4	
	Aquæ dest., q. s. ad	℥iv	120	

M. Sig.: Five to ten drops in wine before meals twice daily.

℞.	Ferri et potassii tartratis	ʒiiss	10	
	Ext. cinchonæ	ʒiiss	10	
	Glycerini	ʒv	20	
	Aquæ dest.	ʒiiss	10	
	Vini (Madeira), q. s. ad	Oii	960	

M. Sig.: Take as a tonic; wineglassful three or four times a day.

R.	Ferri sulphatis	gr. xxiv	1	44
	Magnesii sulphatis	ʒvi	24	
	Acidi sulphurici aromatici	ʒi	4	
	Tinct. zingiberis	ʒii	8	
	Infusi gentianæ comp., ad	℥viii	240	

M. Ft. mist. Sig.: A sixth part twice a day.

℞.	Vini ferri amari	℥vii	210	
	Tinct. nucis vomicæ	ʒiv	16	
	Liq. potassii arsenitis	ʒii	8	

M. Sig.: Two drams in a wineglassful of water after meals.

℞.	Ferri sulphatis exscic.			
	Potassii carbonatis, āā	gr. xxx	1	95
	Ext. nucis vomicæ	gr. v		30

M. Ft. Cap., No. xx. Sig.: One three times daily, after meals.

The following formulas for pills are valuable where one wishes an iron laxative preparation, particularly where there is amenorrhea:

℞.	Ferri sulphatis exscic.	gr. xx	1	30
	Potassii carbonatis	gr. xx	1	30
	Myrrhæ pulveris	ʒi	4	
	Aloes socotrinæ	ʒss	2	

M. Ft. pil., No. xxx. Sig.: Take two or three a day.

℞.	Ferri et sodii pyrophosph	ʒss	2	
	Extracti rhei	gr. xiv		84
	Extracti aloës	grs. viii		48
	Extracti taraxaci, q. s. ft. mass			

M. Ft. pil., No. L. Sig.: Take two night and morning.

Intestinal antiseptics are as much needed as laxatives. The following prescription has been highly recommended as an intestinal antiseptic:

℞.	Creasoti (Beechwood)	mxxxvi	2	16
	Ol. gaultheriæ (Mercks)	mxxxvi	2	16
	Eserin salicylate	gr. 3/5		036
	Pancreatin	gr. lxxii	4	32
	Pulv. ext. cascara sag	gr. xxxvi	2	16
	Pulv. ext. colocynth co	gr. xviii	1	08
	Pulv. oxgall	gr. xxxvi	2	16
	Pulv. acaciæ			
	Aquæ			
	Glycerini			
	Pulv. glycyrrhiæ, āā, q. s. ft. caps., No. 72			

Sig.: One after each meal.

The sulphocarbolates are also excellent intestinal antiseptics and so is beta naphthol. This may be given in two-grain doses three times daily.

It is advisable in treating all cases of chlorosis to administer some intestinal antiseptic.

Often it will be necessary to give some cardiac tonic like digitalis or strophanthus.

NON-MEDICINAL.

Hydrotherapy is of the greatest value as an adjuvant to medicinal treatment. It cannot well be dispensed with.

Enteroptosis may be helped by a cold abdominal douche and by abdominal massage. Elimination of toxic waste matter may be facilitated by warm bath, electric light bath, or sun bath to beginning of perspiration, followed by short cold application by rubbing the patient with a mitten or coarse towel, with water at about 60°, or by giving the patient a cold douche of from 5 to 20 seconds' duration at temperature 70° to 60.° The temperature should be lowered 1 degree daily and the pressure increased. This is a powerful circulatory stimulant and combative of autointoxication as well as a powerful stimulant of vital resistance. Various general graduated cold procedures are invaluable.

For vasomotor spasm and visceral anemias such measures as the general Scotch douche, visceral douches, short percussion douches, alternate compress, etc., are very effective. Cold sponging over the spine and outside and inside of thighs increase elimination and stimulate circulation. Constipation may be relieved and peristaltic activity increased by drinking a glass of cold water, preferably carbonated water, before breakfast; small cold enema; fomentation over liver twice daily, followed by heating compress during interval; wet girdle at night; cold fan douche to abdomen; cold percussion douche to spine; abdominal massage.

General massage, properly given, is a valuable means of treating chlorotic patients who are unable to take active exercise. It acts by increasing the circulation of the blood, by strengthening the muscular system, as an eliminant of waste matter, as a stimulant to the digestive system, as a mild cathartic by increasing peristalsis, as a sedative to the nervous system and as a sleep producer.

Static and Faradic electricity will aid in the treatment of these cases. Faradism to the chest will stimulate respiration and oxygen inhalations will improve the quality of the blood.

Chlorotic patients should drink plenty of water. Under certain conditions water is a hematic. It washes away waste matter and paves the way for growth of new material. Chalybeate remedies may be rendered more effective by adding to them large draughts of water.

MENTAL.

The physician should get his patient into a cheerful, hopeful frame of mind. The hopefulness and optimism of the physician do far more than cure feeble minds and faltering wills. They assist in the cure of every disease he encounters. Alteratives and tonics for the mind are often quite as important and efficacious as alteratives and tonics for the body. Get the patient out of her introspective moods. Cheerful companions, a change of place and scenery, a visit to some chalybeate springs inspire the psychical impulses and form a great incentive to those who are despondent and prone to worry, to exert themselves, and so aid in their own recovery.

Tonics are both mental and material. Hope is a capital tonic. Depressing mental conditions often neutralize the best medical treatment. The prospect of recovery will often bring about satisfactory results almost in the absence of drugs, and certainly often helps out wonderfully a lame line of treatment. Mental tonics should always be combined with material tonics.

Collodion and Acetanilid Dressing.

Dr. F. G. Mohlan, Pueblo, Colo., writes calling attention to the fact that an excellent dressing—one that is aseptic, odorless, clean and white, as well as flexible and adhesive—is collodion, to which is added 5 or 10 per cent. of acetanilid. He says that he has used it for over six years with great satisfaction, in cases in which a collodion dressing is indicated.

The Treatment of Chronic Constipation.

In the treatment of chronic constipation, according to M. J. Krohn, in the *Denver Medical Times*, one must first ascertain the cause and so direct the treatment. He divides the treatment of chronic constipation into three classes: 1, The dietetic; 2, the mechanical; 3, the medicinal. The foods prescribed should be rich in water, and cellulose should be ordered. Thus graham or rye bread, all fruits, except persimmons, fresh vegetables, soups, fats, buttermilk, cider, etc., are of value. If there is gastric hyperexcitability the alkalies are indicated, while all concentrated foods are to be avoided.

If there be an enteritis, such foods as cauliflower, spinach, tender asparagus and mashed potatoes are permissible. He advises the habit of taking cold water before meals and on going to bed.

The mechanical treatment, according to Krohn, consists in massage, gymnastics, electricity, Swedish movements and the cannon-ball massage over the abdomen. Contrary to the opinion of some authorities, he recommends enemas and irrigations as very efficacious.

The medicinal treatment consists of such drugs as belladonna, jalap and cascara sagrada.

If there is a decrease of mucus, ammonium chlorid and sodium phosphate should be given; and when there is excessive hyperacidity, accompanied by constipation, the following combination is recommended:

℞.	Magnesiæ calc.	℥ss	15	
	Pulv. rhei	ʒii	8	
	Sodii carbonatis	ʒi	4	
	Extracti belladonnæ			
	Extracti nucis vomicæ, āā	gr. ii		12

M. Sig.: One-half teaspoonful three times a day one-half an hour before meals.

If the constipation is associated with the absence of hydrochloric acid, the following combination is recommended by this author:

℞.	Acidi hydrochlorici dil.	℥ss	15	
	Strychniæ sulphatis	gr. 1/3		02
	Tincturæ rhei q. s. ad	℥vi	180	

M. Sig.: One tablespoonful in a wineglassful of water three times a day, before meals and taken through a glass tube.

In those cases occurring in adipose individuals with a tendency to passive congestion of the intestinal canal and having a tendency to hemorrhoids, Krohn recommends the neutral salts, such as magnesium sulphate, sodium phosphate and sodium and potassium tartrate. The very drastic purgatives should be avoided.

F. E. Prewitt, in the same periodical, after enumerating the various causes of constipation, states that the medicinal treatment of constipation is of the least importance. Not infrequently the slightest change in the diet will overcome the constipation. Consequently, the diet should be carefully inquired into and carefully regulated, remembering that single articles of food, such as milk, may serve as a laxative for one person and tend to constipate another. In addition to giving a somewhat abbreviated diet list, he emphasizes the importance of instructing the patient to go to the toilet regularly each day at the same time, whether there is a desire or not, and at the same time advising him not to put in his time reading a newspaper or a book while at stool, but to keep his mind concentrated on the purpose for which he is there, and to remain there for fifteen minutes if necessary. He is of the opinion that vibratory massage will in time occupy a place in the treatment of constipation. Gymnastics are invaluable in the treatment of constipation, and can be carried out at home if a gymnasium can not be obtained. Of the medicinal preparations he regards cascara sagrada as the best preparation and jalap is considered next in order of efficiency and acts best as a rule combined with podophyllin and aloes and belladonna.

Inflamed and Protruding Piles.

The following combination is recommended by the same periodical in the treatment of inflamed and protruding piles:

℞.	Cocainæ hydrochloratis	gr. iiss		
	Sol. adrenalin. chlorid. (1-1,000)	f.ʒss	2	
	Bismuthi subnitratis	gr. x		65
	Petrolati liq	℥i	30	

M. Ft. unguentum. Sig.: Bathe the parts in cold water and apply the ointment after each stool.

Acute Nephritis in Scarlet Fever.

In the treatment of true nephritis following scarlet fever, Hughes-Bennett, according to an abstract in the *Med. Review of Reviews*, recommends the following combination:

℞.	Potassi acetatis	ʒii	8
	Spts. etheris nitrosi	f.℥ss	15
	Aquæ q. s. ad	f.℥ii	60

M. Sig.: A teaspoonful every two hours well diluted in water.

Or:

℞.	Hydrarg. chloridi mitis		
	Pulv. scillæ		
	Pulv. digitalis, āā	gr. ¼ to ½	015-.030

M. Ft. pil. No. i. Sig.: One such pill every three or four hours.

In addition to the foregoing treatment, saline purgatives are recommended with hot-water or hot-air baths taken twice daily.

And in scarlatinal rheumatism some preparation of iron should be given alternating with the following combination:

℞.	Ammonii salicylatis	ʒii	8
	Elix. simplicis		
	Syrupi simplicis, āā	f.℥ss	15
	Tincturæ cardamomi co	f.℥i	30

M. Sig.: One teaspoonful well diluted in water four times a day.

Multiple Warts.

The following combination is recommended by the *Med. Review of Reviews* to aid in the removal of multiple warts:

℞.	Chloralis hydratis		
	Acidi acetici	f.ʒiss	6
	Acidi salicylici		
	Spts. etheris nitrosi, āā	f.ʒi	4
	Collodii	f.ʒiv	15

Misce. Sig.: Apply to the warts twice daily.

Medicolegal

Cross-Examination of Physician—Discrediting Evidence.

The Supreme Court of Washington says, in the personal-injury case of Williams vs. Spokane Falls & Northern Railway Company, that the plaintiff, no doubt, waived his privilege when he permitted a physician who had examined him in his professional capacity to give his testimony without making any objection thereto. But he had a right to discredit the witness by showing interest or bias in the case, and legitimate cross-examination was perfectly proper for that purpose. A wide latitude is usually, and should be, given on cross-examination, the extent of which must be governed largely by the discretion of the trial court. Such discretion will only be reviewed for abuse thereof.

The principal defense in this case was that the plaintiff was in a large measure simulating his injuries. The defendant's evidence tended to show that he was afflicted with what the physicians termed hysterical paralysis, and that the pendency of a lawsuit had a strong tendency to prevent improvement in such cases. Evidence with regard to the frequency of the visits to him at the hospital of the defendant's claim agent was received by the trial court on the theory that it had a tendency to rebut the evidence of the physicians by discrediting their statements that the plaintiff was suffering from hysterical paralysis, because under such circumstances the attending physicians would not have permitted the claim agent to visit the plaintiff. The Supreme Court holds that the evidence was admissible for that purpose, and for that reason only.

Power of State Association—Certificate Requirements.

The Supreme Court of Alabama says, in Brooks vs. State, that section 5333 of the code of 1896 reads: "Any person who practices medicine or surgery without having first obtained a certificate of qualification from one of the authorized boards of medical examiners of this state must, on conviction, be fined not less than $25 nor more than $100." Section 3262 says: "The standard of qualification, the method or system and the subjects of examination of practitioners of medicine shall be prescribed by the Medical Association of the State of Alabama and must be observed by the boards of medical examiners." It will be observed, the court continues, that the lawmakers have clothed the Medical Association of the State of Alabama with full authority to prescribe the rules and regulations governing the issuance of certificates to medical practitioners, and the Alabama statutes in this respect are not only intended as a means of maintaining a high standard in the ranks of the medical profession, but are designed to protect the public from imposition and fraud by authorizing the state medical association to prescribe the rules and restrictions governing the issuance of certificates to those engaged in or desiring to engage in the practice of medicine.

The state medical board adopted in 1899 the following ordinance: "Be it ordained by the Medical Association of the State of Alabama that hereafter all certificates conferring the privilege of practicing medicine in this state, issued by county boards of examiners, shall be countersigned by the senior censor of the state association before the same shall become legal and valid." It is to be noted, the court says, that every certificate issued by a county board after the adoption of the above had to be countersigned by the senior censor, else it would be invalid. The state proved a *prima facie* case against the defendant (party first named, who was convicted of a violation of section 5333, quoted above), who attempted to defend under a certificate issued by the county board, Jan. 29, 1900, but which had not been countersigned by the senior censor of the state, and which was insufficient, and an objection by the state to the introduction of same was properly sustained.

There was no error in sustaining the state's objections to the defendant's attempt to introduce a diploma or proof of the length of time he had practiced medicine. These facts may have been sufficient to authorize the county board to issue him a certificate without undergoing an examination, but could in no sense make valid a certificate not issued in conformity with the rules of the state association.

It was not competent for the defendant to show the action of the Medical Society of Marion County, since he did not show that it issued him a certificate prior to the adoption of the ordinance in 1899. Neither was it competent to show that other physicians had no certificates or had not stood examinations. If they were violating the law it did not justify the defendant in doing so.

Liability of Company Silent When Services Rendered.

The Supreme Court of Rhode Island says that the case of Nelson R. Hall vs. New York, New Haven & Hartford Railroad Company was brought to recover $1,573.75, with interest, for services rendered during a period of twenty weeks and for supplies furnished by the plaintiff, a physician and surgeon, to the defendant's employé, a carpenter, who was injured in the course of his employment at its power station in Warren, R. I., by steam and hot water in an accidental explosion. The company denied liability and claimed that it never engaged the services of the plaintiff. But it appeared that on the day after the accident the physician sent to New Haven, where the principal offices of the company were located, by the foreman under whom the man was working when injured, a report, stating that on the preceding morning he was called to the power station in Warren by the station agent to attend the man, naming him, who had been scalded by steam and hot water which came from condenser pipe. "The scalds," the report continued, "appear to be of the second degree and involve both legs and the lower third of both thighs. The patient now suffers from prolonged shock and is much exhausted. . . . Trained nurse is in attendance." What the foreman did with the report did not appear, but at the trial the company produced it, and in the absence of explanation as to how or when it obtained possession of the same it was not unreasonable to infer that it was delivered to the company with reasonable celerity.

What was the duty of the company in the premises? To let the physician remain ignorant of the truth of the invalidity of his employment in its behalf? To permit him to incur large expense and employ valuable time in a malodorous and repulsive employment in the faith that he would be compensated by a responsible company, while that company intended that he should be compelled to resort for payment to the nonresident injured mechanic, whose expenses would be greatly increased and whose resources would be greatly diminished, if not cut off, by this very accident, which would deprive him for a long time of the ability to perform his daily toil? The ordinary physician is not an eleemosynary institution, and, although he often does perform services for charity, it can not be expected that he will compete with the hospitals that are established for general public use. It was the duty of the company to early apprise the plaintiff of the true condition of affairs; to either disaffirm the act of its station agent in toto (entirely) or to explain the extent of his authority to the physician in order to give him the opportunity to make further arrangements for treatment of the patient beyond the time of any authorized limited employment. But the company did neither; it neither accepted nor rejected the services of the physician under his supposed employment, but it elected to *remain silent.*

The evidence also disclosed that on two occasions, the first of which was soon after the accident, the claim agent of the company and its physician visited the patient to ascertain if he was in a condition suitable for removal to a hospital, and after examination on each visit found that he was not. But no fault was found by them with the treatment that he was receiving. When the physician rendered his bill for $1,573.75, and on two later dates sent similar bills, no notice of them was taken by the company. Similar silence was maintained concerning the bills as was observed in the matter of the report.

Under these circumstances, whether or not the company ratified the act of its station agent in employing the physician to attend the injured man, the court holds, was a question of fact to be determined by the jury. As their verdict was for the physician, without any special finding, it might be safely assumed that they found a preponderance of evidence satisfying them of such ratification. This court can not say that the verdict in this respect was against the evidence. Moreover, the court says that, although the physician had rendered several bills to the company, each showing the amount charged by him for his services, for which this suit was brought, the company introduced no testimony tending to contradict that of the physician, who went into a minute and detailed explanation of the nature of his services and testified that the prices charged by him for the same were reasonable. In such circumstances the court is unable to say that the verdict was excessive.

1 Japanese Naval Sanitation. B. K. Takaki, Tokyo, Japan.
2 *Banti's Disease (Splenomegalia and Cirrhosis of the Liver). M. Einhorn, New York.
3 *Brief Résume of the World's Recent Cancer Research. W. S. Bainbridge, New York.
4 *Habitual Constipation, Viewed from the Standpoint of Modern Evolution of Dietetics, is a Physiological Phenomenon. C. D. Spivak, Denver.
5 *Acroparesthesia. W. W. Lesem, New York.
6 *Two Cases of Varicose Veins Successfully Treated with the X-Rays. J. C. McGuire, Washington, D. C.

2. **Banti's Disease.**—Einhorn has seen eighteen cases, which he has tabulated and placed in three groups: 1. Pure form; splenomegalia, anemia, cirrhosis of the liver, ascites. 2. Hemorrhagic form, showing in addition to the symptoms just enumerated, gastric and intestinal hemorrhages. 3. Splenomegalia, enlargement of the liver, anemia, sometimes associated with grave gastric symptoms. Treatment depends on the stage of the disease and the group to which it belongs. In some cases extirpation of the spleen may be considered. The x-ray treatment has given good results. Gastric hemorrhages should be treated according to the accepted rules. The physician may be a little bolder in giving food in these cases. Stomach symptoms should be combated and a strengthening diet is indicated. The administration of sodium iodid with iron and sometimes arsenic is generally followed by good results.

3. **Résumé of World's Cancer Research.**—Bainbridge states that cancer occurs with the same essential characteristics throughout the vertebrate creation. There is a variety of conflicting evidence in reference to the influence of diet on the development of cancer. However, cancer is comparatively rare in hot countries, especially in those whose inhabitants subsist largely on vegetable diet. With certain exceptions it seems to be prevalent where animal diet is mostly consumed. Black races are remarkably immune from cancer, yellow races are more prone to it, while the white races are the most susceptible. It occurs when the tissues are undergoing retrograde metamorphosis. Cancer is undoubtedly on the increase. The principal increase involves the alimentary tract. There are certain districts called "cancer belts." Such areas are usually low-lying and damp. Women are attacked by cancer far earlier and more often than men. Much recent experimental work points to the cell as the essential element in the development of cancer. The parasitic theory is discredited by the Harvard Commission. The report of the Imperial Cancer Research Fund destroys all known theories of the origin of cancer, but proposes no new theory. Surgical treatment has been established on a firmer basis than ever before.

4. **Habitual Constipation.**—Spivak summarizes his paper as follows: Habitual constipation in a great many cases is due to a mistaken diagnosis. The patient makes the diagnosis himself, based on his sensation only. Once the diagnosis is made, and then corroborated by the physician, it becomes an etiologic factor. The tendency of civilized life in general and of modern dietetics in particular is toward the production of lesser quantities of fecal matter and less frequent evacuation. There is no doubt that the habit of regularity is beneficial, but no one should allow every unusual sensation to become a source of morbid concentration. The treatment of habitual constipation should be directed more toward rectifying the errors of the mind than those of the body. The patient should be impressed with the fact that certain foods are better absorbed than others, and that it is not imperative for the preservation of good health to have a movement of the bowels daily, nor is the small quantity indicative of disease.

5. **Acroparesthesia.**—Lesem defines acroparesthesia as an affection of the peripheral nerves, characterized by burning, pricking, pins-and-needles, numb, crawling, itching or breaking sensations disturbed usually over the extremities. Not infrequently, however, the head, face, chest, back and abdomen are involved. The viscera are rarely affected. Among 200 cases seen by Lesem, 94.5 per cent. occurred in women. The majority of the patients were between the ages of 30 and 40 years. Circulatory and gastrointestinal disturbances appear to be the cause of the large majority of the writer's cases. Menstrual and puerperal disorders occurred in 12 per cent. Occupations such as tailoring and constant immersion of the hands in water occurred as an etiologic factor in 1 per cent. The symptoms vary with the intensity of the disease. The course of the disease is either short or it becomes chronic and progressively worse. The types most susceptible to treatment are those dependent on puerperal and climateric disorders and on autointoxication.

6. **Varicose Veins Successfully Treated with X-Ray.**—McGuire reports two cases. The first patient was a woman, aged 45, with eczema of both legs, complicated with varicose veins and an ulceration on the right leg. The ulcer resisted all treatment, until the application of the x-ray. This caused inflammation of the skin, which extended over the whole surface of the leg. The treatment was stopped for four days, when it was again tried. Inflammation resulted, but during the next five days, without the application of the x-ray, the dermatitis gradually subsided and by the end of the week had

disappeared. The ulcer completely healed and the varicose veins disappeared. The second patient was a man 50 years of age with a large bunch of varicose veins on the right leg. Treatment by the *x*-ray is gradually reducing the tumor and without causing any great reaction of the tissues. The rays cause contraction and atrophy of the tissues and those of low vitality easily break down.

10 Fracture of the Fifth Metatarsal Bone by Inversion. F. J. Cotton, Boston

8. Care of Far-Advanced Cases of Pulmonary Tuberculosis.—Bonney summarizes his paper as follows: 1. About one case out of every four or five may reasonably be expected to exhibit a pronounced diminution of temperature by the end of a week or ten days. 2. The remaining cases do not show any bad results from its employment, other than those due to the occasional intolerance of the system for the serum of a horse. This so-called reaction, which is independent of the specific ture of the remedy, but common to all other serum preparations, bears no relation to the ultimate results obtained. 4. Some cases show marked improvement in spite of temporary discomfort in the way of chills, fever, urticaria and painful swelling with stiffness of the joints, while others exhibit no improvement, although there is entire absence of constitutional disturbance. 5. Reaction may take place within twelve hours after the use of the serum or it may be delayed for six weeks. 6. Occasionally the improvement is delayed indefinitely until the occurrence of the reaction, following which there may be complete and enduring subsidence of the fever. 7. As a result of the serum the temperature either may subside to normal or may be reduced several degrees, remaining, however, somewhat elevated. 8. He has not been in favor of its continued subcutaneous employment, and has given, as a rule, not over four or five doses at intervals of one or two days and awaited results. 9. During the past nine months he has practiced the tentative administration of the remedy by the rectum for ten or twelve doses before resorting to its hypodermatic use, in order to avoid the discomfort which sometimes follows its injection into the tissues. 10. He has seen unquestionably good results attend its use even when streptococci were not found in the sputum, and believes that even under such conditions the clinical evidences of a persisting sepsis may sometimes afford, from a humanitarian standpoint, a warrantable basis for its use.

15. Electrolysis in Stricture of Eustachian Tubes.—Yates reports four cases of deafness due to stricture of the Eustachian tubes in which electrolysis was employed successfully. The apparatus consists of a gold wire, olive tipped, bougie attached by a cord to the negative pole of a galvanic battery of sufficient voltage to overcome the body resistance. Forty volts is strong enough. An ordinary hand electrode is connected with the positive pole of the battery and grasped by the patient. The Eustachian catheter, insulated by winding with rubber tissue, is placed in position and the ear inflated in the ordinary manner to make sure that the catheter is properly situated. The iodin, menthol and camphor vapor is used in inflation, and has a valuable influence in preventing infection. The bougie is now passed through the catheter and on through the tube as far as it will go without exercising force, and the current turned on until three to five milliampères are indicated by the meter. No stronger current is necessary. The sensations of the patient must also guide the surgeon, for pain should be avoided. Having engaged the stricture, the bougie is allowed to lie snugly in contact for a few moments, when it will be found possible to advance the point a short distance. This maneuver is repeated until the stricture is passed and the surgeon is satisfied that the tube is open, when the bougie is slowly withdrawn and the current turned off. Inflation should be performed before, but not immediately after the bougie is used, for fear that air should be forced through a possible puncture of the mucous membrane into the loose surrounding tissues and so set up a traumatic emphysema. Treatments with the bougie should be about ten days apart, with one or two inflations between.

19. Cesarean Section.—Aspell reports 5 cases. In 2 the existence of a deformed pelvis was the indication for Cesarean section. In 2 cases labor was complicated by the presence of a fibroma. In 1 of these cases the tumor did not obstruct the delivery, but in the uterine contraction, after the third stage, the tumor of its own weight obstructed the free discharge of lochia and became so great an irritant that its removal was imperative in the first week of the puerperium. In the second case the tumor was situated in the broad ligament.

24 Case of Banti's Disease. H. J. Whitacre, Cincinnati.

22. Measure for Quantity of X-Rays.—Dunham's instrument consists of a selenium cell, which is placed inside of a wooden pill-box and surrounded by tungstate of calcium. This and a volt meter are placed in series in a direct current of not less than 60 volts. When this is placed before an *x*-ray tube the tungstate of calcium is caused to fluoresce and the light derived from the fluorescence causes the resistance of the selenium cell to be reduced (as does any light). The fluorescence is, of course, much less powerful than a 15-candle power lamp. This lowering of resistance in the cell allows the current to flow more readily, and this can be directly measured by a very sensitive volt meter. The next instrument depends for its action on the fact that a 2 per cent. solution of iodoform in chloroform is very easily and uniformly affected by the *x*-rays. Its appearance when so treated varies from a light pink to a very dark reddish brown. The second instrument is as follows: The selenium cell and volt meter are put in series as before, but no fluorescent salt is used. The wooden box is removed and the cell placed in a light tight box. The resistance of the selenium cell is reduced by the electric lamp beyond a partition. The light must pass from a lamp to the cell through the bottle because of the small aperture. To make this doubly certain the opening is fitted with a small cylinder so that the rays must pass as desired. When it is desired to measure a given dosage all that is necessary to do is to fill the bottle, place it in the box and make the reading. The solution is clear and practically all the light passes to the cell. The resistance drops and the voltage as read on the meter goes up. The bottle is now removed, laid on the surface of the patient near the part to receive the irradiation. After the treatment it is quickly placed in the box and the reading taken. The quantity of *x*-rays will be read by the difference of the voltage before and after the exposure.

28 *Peculiar Pressure Symptoms Due to Enlarged Tuberculous Bronchial Glands. T. S Westcott, Philadelphia.

28. Pressure Symptoms Due to Enlarged Bronchial Glands.—The subject of this report first came under Westcott's notice when she was just past three months of age. The upper part of the chest was noticeably high and full. At the age of two months the baby began not to nurse well and the stools showed signs of indigestion. She breathed with effort. Examination of the lungs showed only a weakened respiratory murmur. Venous enlargements were noted over the anterior surface of the chest; the cheeks showed some stellate capillary venous enlargements and the larger veins about the eyes and on the temples were noticeably full and clearly marked. The evidences of intrathoracic pressure gradually became more distinct. An irregular fever appeared. Digestive disturbances became more marked. Cyanosis of the fingers and hands was constantly present in some degree. Death ensued one month later, the child being then four months old. At the necropsy both lungs were found thickly studded with miliary tubercles. At the root of the lungs, in such a position as to press on the trachea to some degree, but more particularly on the descending cava, was a mass of tuberculous glands the size of a pigeon's egg, the center one of which had broken down and contained about 20 minims of purulent fluid. A few scattered tubercles were found in the spleen. The other organs were not affected.

In discussing the possible origin of the infection in this case the mother stated that at the time of her confinement at the hospital a patient was dying of pulmonary tuberculosis in a room across the hall from her room. The fact that the child was only two months old and that the large bronchial gland showed advanced disease makes it certain that the original infection must have occurred soon after birth by inspiration.

34 Further Observations on Citrate of Soda. J. W. Van Derslice, Chicago.

29. Multiple Rhabdomyoma of Heart Muscle.—The patient from whom Knox and Schorer obtained this specimen was only 7 months old. The tumors were situated in the myocardium and in the right and left ventricle, the latter being pedunculated.

32. Case Simulating Peptic Ulcer.—Adams reports the case of a girl, 11 years of age, who complained of a sudden severe pain in her stomach and soon vomited blood in large quantities. She vomited blood several times that day and incessant hiccough followed. Pain was less atter vomiting, but persisted, and the abdomen remained very tender to touch. The patient did not vomit again, although slight nausea was present. A probable diagnosis of peptic ulcer was made, but Adams was of the opinion that the blood did not come from the stomach. The uvula of the patient was adherent to the right tonsil. Adams separated this adhesion after the patient had vomited the blood without exciting any bleeding. He inclined to the belief that the vomited blood came from the irritated fauces by a voluntary effort resembling hiccough. The clinical findings were opposed to the original diagnosis.

46 Mastoid Operations. T. H. Shastid, Marion, Ill.
47 Multiple Chancre. A. F. Büchler, New York.
48 Treatment of Cancer of Breast. B. MacMonagle, San Francisco, Cal.

42. Influence of Rest, Exercise and Sleep on Gastric Digestion.—As the result of a number of carefully conducted experiments Friedenwald arrives at the following conclusions: 1. In persons with normal digestive powers it makes but little difference whether the individuals rest, exercise or sleep after meals; though after violent exercise or sleep the gastric digestion is very slightly impaired. 2. In patients suffering with superacidity and subacidity it is best to order rest after meals; after violent exercise or during sleep the digestion is impaired in these cases. 3. In patients suffering with motor disturbances of the stomach, it is best to prescribe moderate exercise after meals, for rest, violent exercise or sleep disturbs the digestion under these conditions.

44. Lateral Anastomosis of Intestine.—Sanderson's method in some respects copies Connell's method. An opening is freely made into the lumen of the guy at both points where the anastomosis is desired. This opening may be linear or oval and should be large enough to equal, if not exceed, the lumen of the guy. A guy suture of silk or silkworm is passed in to hold the ends of the opening in approximation, two sutures being necessary. Beginning near one the bowels are sewed together from the mucous membrane side approximating the serous coats. The suture employed is a continuous right angle through-and-through suture, all work being done within the lumen of the intestine. Reaching the other guy suture, a knot is tied in the running suture and the guy suture is removed. The running suture is continued around to the starting point, as in the Connell method. The suture material to be used may be silk or catgut.

50. Treatment of Gonorrhea by Irrigation.—Miller employs Valentine's method, except that during the first three days, when the urethra is highly inflamed and very sensitive, he uses only warm sterile water, which thoroughly cleanses the urethra and also allays the inflammation. After the mucosa becomes less swollen the germicide, which is then used, is more effective.

56. Treatment of Fractured Ribs.—After determining the nature of the fracture, Woodward scrubs the skin with alcohol or ether to remove all the oily material. The chest is then immobilized by strips of plaster. The plaster which he has found best for the purpose is that known to the trade as Z O plaster. The width of the strips to be employed varies according to the obesity or the reverse of the patient, but as a rule strips two inches wide are used. One of these is measured around the patient and cut of a length to reach from a point one inch beyond the mid-sternal line to a point one inch beyond the mid-spinal line. The other strips are cut the same length, about twelve pieces being necessary. The first strip of plaster is applied parallel to the ribs, i. e., from in front backward and upward, but is placed well below the point of fracture, in some cases nearly as low as the crest of the ilium. The front end is attached first, and then while making considerable tension on the strip, it is carefully and smoothly applied upward and backward to a point just beyond the spine. The second strip is attached in front at a point level with the nipple, and is passed downward and backward to a point in the lumbar region. The third strip follows the direction of the first, overlapping its upper half. The fourth overlaps the second, etc. The line of overlapping should fall directly over the seat of fracture. When completed, the chest should be strapped from a point slightly above the ilium to a point well into the axilla. A four-inch gauze bandage is now evenly applied over the entire chest and abdomen. This makes a soft lining for the starch jacket, which is next applied.

Crinoline used for starch bandages is of different qualities, and it is not always the most expensive crinoline which is the best for the surgeon's purpose. The most suitable quality is saturated with starch. It should be made into bandages four or five inches wide, not rolled too tightly. These bandages should be immersed in tepid water a few moments, but should not be squeezed much, as this wastes the starch. They are then applied over the gauze bandages, and like them form a jacket over the entire chest and abdomen. The crinoline should not be applied with much tension, as it shrinks in drying, and may prove too tight. If the crinoline is of proper quality each layer will agglutinate itself to the one underneath and the edges of the bandage will not curl up. Two safety pins in the end of the bandage are all that is necessary. To hold the jacket in its original position, Woodward makes suspenders by passing a three-inch muslin bandage over each shoulder, the ends meeting low down in front and behind. These are attached to the starch jacket by a series of safety pins. The patient is now placed on his back in bed until the jacket dries, when it will be found straight and smooth, and in this condition it will remain indefinitely. The jacket is not heavy or uncomfortable, and immediately on its application the patient feels a sense of security in taking a long breath without the fear of the sharp pain which he had before.

58. New First Aid Packet.—The dressing which Angney has adopted consists of two compresses, each three by three and one-half inches of gauze with absorbent cotton in the center; one is tacked permanently on the bandage; the other is placed loosely on the top of the first compress, and overlying the second compress are a few layers of loose gauze which can be used by a physician for tamponage. The compresses are dusted with boro-salicylic acid. When one wound is present, the double pad can be placed on it; if two are present or if the wound be a long one, then the compresses can be separated and placed in position. There is sufficient bandage to wrap around the leg in its widest diameter or for use around the trunk. The end of the bandage is split, which is a satisfactory method of fixing it in position. Two strips of adhesive plaster are added.

62. Peculiar Case of Appendicitis.—The subject of Bispham's report complained of severe pain in the back just below the articulation of the twelfth rib and spine on the right side, one inch from the column. The abdomen was not distended and there was no pain on palpation, except at the point mentioned where there was also some swelling, but no redness. He vomited only when food was taken. His bowels had not moved for several days. Acting on the supposition that there was pus somewhere beneath the localized area in the back, Bispham made a linear incision parallel to the spinal column and directly over the area of swelling and tenderness. A small hematoma was found, about the size of a pigeon's egg, in the latissimus dorsi muscle. This muscle was cut through, and the liver, kidney, colon and pelvis were examined carefully. Everything seemed to be normal, however, with no adhesions or exudates of any kind. The wound was closed and dressed. For the next few days the temperature went up and there appeared some tympanites with pain and tenderness over the right side of the abdomen. Owing to the patient's poor condition, no further operative procedure was undertaken until the third day, when the old incision was opened and several pus cavities were found in the muscular tissue of the back, next to the peritoneum. Further exploration revealed a perforation of the tip of the appendix and a localized peritonitis. There was also a small ulcerated hole through the peritoneum just beneath the appendix which communicated with the cavities in the back. The patient died shortly after the operation.

6 Case of Sudden Death Possibly Due to Vagus Inhibition. E. D. Telford.
6½ *Bacterial Action of Compounds of Silver. C. R. Marshall and F. F. M. Neave.

1. **Pulmonary Edema.**—Wethered discusses the clinical history of this condition, with special reference to its causes.

2. **Acute Nephritis.**—In this paper Gullan takes up parti larly the treatment of nephritis. To produce a free diaphore he prescribes the follownig mixture:

Tincture of jaborandi	m. xxx	2
Sodium benzoate	gr. xv	1
Chloroform water	℥i	30

M. Sig.: One ounce every four hours.

3. **Food and Food Preservatives.**—Jones' paper is based on the report of the London departmental committee on food preservatives made in 1901 and is largely a review of what has been published before.

5. **Human and Bovine Tuberculosis.**—Raw reiterates his previously expressed views on this subject, namely, that human and bovine tuberculosis are distinct varieties of disease, but that the human body is susceptible to both, and especially to bovine tuberculosis in the milk-drinking period of life. He is at present collecting the blood of animals, killed for tuberculosis, the serum of which, after careful preparation, he proposes to use in vaccinating children whose parents died of phthisis, with a view to protecting them against that disease.

6½. **Bactericidal Action of Compounds of Silver.**—An important investigation was recently undertaken under the authority of the therapeutic committee of the British Medical Association by C. R. Marshall and E. F. Macleod Neave to determine the comparative value of the various compounds of silver as bactericides and antiseptics. The following preparations were examined:

	Percentage of silver.
Collargol	86.6
Silver fluoride	81.7
Silver nitrate	63.6
Itrol	60.8
Actol	51.5
Argentol	31.2
Ichthargan	27.1
Argyrol	20.0
Albargin	13.4
Nargol	9.6
Largin	9.4
Novargan	7.9
Protargol	7.4
Argentamine	6.4
Argonin	3.8

The solutions for experiment were made each to contain a definite percentage of silver so that comparisons are made between strengths of the different preparations containing equal percentages of silver. Bactericidal power was determined by noting the percentage of silver necessary to destroy organisms in a mixed culture obtained by allowing uncooked beef to stand in water in an open vessel for four to six weeks. Experiments were also made with a pure culture of *Staphylococcus pyogenes aureus*. The antiseptic action was tested (1) by observing the time taken by minced cooked beef to putrefy in presence of solutions of silver compounds of known strength, (2) by inoculating an agar medium containing a definite quantity of the various silver compounds. The power of diffusion of the various compounds was tested by immersing glass tubes filled with coagulated agar and inoculated with *Staphylococcus pyogenes aureus* in solutions of the various silver preparations and observing the distance to which the silver penetrated, as shown by visible discoloration and also by the antiseptic action. Argyrol excelled the other preparations in diffusion power.

The authors conclude with the following summary: The experiments show that as regards bactericidal action the various silver compounds investigated fall into three groups: 1, Those which are powerfully bactericidal; 2, one—nargol—much less powerfully bactericidal; 3, two—argyrol and collargol—which possess practically no bactericidal action whatever. The first group includes most of the substances investigated, namely, silver nitrate, silver fluorid, actol, itrol, argentamin, argentol, albargin, argonin, ichthargan, largin, novargan and protargol. The bactericidal action of these in solutions containing the same percentage of combined silver is closely similar, and it is practically impossible to place them in any order of activity which would be true under all circumstances. As argyrol and collargol are not bactericidal, it is evident that the amount of silver which a compound may contain is no criterion of its bactericidal power. Moreover, in view of the results obtained with argyrol, it seems impossible to attribute the good effects which many clinicians have obtained with it to its bactericidal action.

7. **Cancer of Stomach.**—Robson emphasizes the importance of an early diagnosis of cancer of the stomach in order that a radical operation may be performed at the earliest possible moment. If necessary, an exploratory operation should be done, even in cases where the disease is advanced and a tumor is perceptible. When the disease is too extensive for any radical operation to be done, the palliative operation of gastroenterostomy is indicated. It can be done with very small risk and may considerably prolong life. Robson has found that some cases, thought to be cancer, too extensive for removal, have cleared up after a gastroenterostomy, the patient getting quite well. In cases of disease of the cardiac end of the stomach too extensive for removal, the operation of gastrostomy may considerably prolong life and prove of great comfort to the patient by preventing death from starvation. Even where the disease is too extensive either for removal or for a gastroenterostomy, the operation of jejunostomy may prove of service to the patient. Where a radical operation can be performed, the thorough removal of the disease may bring about as much relief to the patient as does the operation for the removal of cancer of the breast, uterus, and other organs of the body. In some cases a complete cure may follow.

10. **Improved Milk Supply.**—The object of Chalmer's paper is to consider what alteration in existing legislation seems to be necessary to enable local authorities to insure the provision of a pure milk supply in the city of Glasgow.

11. **Sterilization of Tuberculous Sputum.**—Kirkland and Paterson describe the method employed at the Brompton Hospital. To sterilize sputum an iron vessel is used which is provided with a movable lid and which has at the bottom two steam jets so arranged that a circular motion is given to the contents. The sputum having been poured into this vessel, the lid is screwed down and steam is allowed to enter until a pressure of 15 pounds has been obtained. The contained sputum is allowed to boil under the action of steam for a period of 20 minutes, after which it is allowed to cool to a temperature somewhat above 100 F. and is emptied into the drain by opening a valve in the bottom of the sterilizer arranged so that all the contents can drain away. For cleaning the sputum pots they employ a large iron tank having the necessary valves for admitting water and steam and a valve in the bottom of the tank through which the contents could be emptied into the drain. Inside the tank is a cage which can be raised out of or lowered into, the tank at will. This cage is constructed of brass tubes framed and braced together. On the horizontal tubes the sputum cups are suspended by their handles and the covers of the cups are placed in suitable trays provided in the cage. For the purposes of sterilization and cleaning, the cage full of soiled sputum cups and covers is lowered into the tank. Water is admitted into the tank and boiled by the admission of steam. After boiling for 20 minutes this water is emptied and the process is repeated. The cage is then raised and the cups and covers are removed. By this method much less handling of the cups is required and the cleaning of both cups and covers is found to be more thoroughly performed than when washed by hand. The saving of time effected by this method of washing the cups enables the same staff as was formerly employed in collecting and washing the cups to wash the handkerchiefs in addition. The soiled handkerchiefs are conveyed from the wards in covered pails and are at once placed in the sterilizing and washing machine, where they are first sterilized and afterwards washed. After washing they are taken out and placed in the hydro, which, with the calender, is in a separate room. After being dried in the hydro they are passed through the calender and are then folded and returned to the wards.

16. **Action of Strontium Salts on Coagulability of Blood.**—From personal experiments Nias is convinced that the lactates of strontium and magnesium, in doses of from 1 to 2 grams, are serviceable substitutes for the salts of calcium when the latter are not absorbed from the alimentary canal.

20. **Diagnosis of Typhoid.**—Harrison suggests the routine examination of the blood by culture as a rapid means of diagnosing typhoid fever. The method should be applied to every case of fever. The method employed is as follows: The patient's arm, at the bend of the elbow, is cleaned with soap and water, turpentine, 1 in 1,000 solution of perchlorid in rectified spirit, and ether rubbed on; ether is then dropped on from a drop bottle every few seconds till the puncture is made. The vein is made prominent, as for venesection. During this time an antitoxin syringe of 10 c.c. capacity is being sterilized by filling with oil at 160 C. As soon as the syringe has cooled down to the temperature of the hand, the needle is given a final dip in the oil to destroy any germs which might have fallen on its point during the cooling of the syringe barrel; and is then, almost at once, run into the vein. The puncture of the vein is very simple; the needle is kept almost parallel with the vein, the point is run through the skin and pushed steadily on; the eye of the needle should look upward and the point is bound to enter the vein. The syringe is filled by withdrawal of the piston and the needle withdrawn from the vein. A flask of 500 c.c. of broth is opened in the usual manner, and after expressing a few drops of the blood to wash off any germs which might have fallen on the eye of the needle during the

necessary interval between withdrawal of the needle and opening of the flask, the whole of the 10 c.c. of blood is forced into the broth and the flask replugged. The flask of broth with the patient's blood is then put into an incubator and kept at a temperature of 37 C. In a successful result, after 20 hours, the broth is often found to be turbid, particularly if the culture is made early before agglutinins and bactericidal substances have developed in the blood. A loopful of the turbid broth is put out on a slide, covered with a slip, and examined with an eighth-inch objective. If motile bacilli are seen, a portion of antityphoid serum, of which the maximum agglutinating power has previously been ascertained, is suitably diluted with distilled water, a loopful of the diluted serum placed at the edge of the slip, and the effect watched. If agglutination occurs, one is in possession of the information that a patient admitted with fever has a motile bacillus circulating in his blood, which bacillus is agglutinated by a suitable dilution of antityphoid serum.

21. **Rider's Sprain.**—Ievers insists that rider's sprain deserves a most careful study, both as to its causation and treatment. The muscle engaged is not what is sometimes erroneously called the "tailor's muscle," but the adductor longus, which may be affected to any extent, varying from a slight sprain to more or less complete rupture of the muscle and its sheath or tendon. In severe cases the point usually torn is at its insertion into the rami of the pubes. The sheath of the muscle may be completely severed in addition to its tension, and the belly of the muscle forming a large tumor in the upper or inner third of the thigh; more often than not it is in the right thigh that the muscle gives way, and when there is much laceration one often finds very extensive ecchymosis extending in all directions from the part immediately implicated. The cause is usually owing to the extra effort occasioned in keeping one's seat, either in taking a fence, when the horse happens to peck badly, or when in jumping a high wall the horse unexpectedly attempts to change, thereby causing the rider a sudden jar, the extra strain being sufficient to cause the muscle to give way. In the treatment, Ievers advocates a somewhat similar procedure to that of a fractured bone. He has, therefore, advised an appliance for this purpose, formed of the stoutest elastic band made, which should be five inches in width, stiffened by a couple of slips of whalebone let in at intervals, and cut so as to envelop in its circumference the upper portion of the thigh, taking care that the opposite ends do not approximate by two and one-half inches, so as to admit of the required stretch to get a good grip when fastened by means of three straps and double or whole buckles on outer aspects of thigh. Further, it is essential that the upper edge of band be brought right up to the fork. A suitable pad should be inserted inside the elastic band over the seat of injury, and finally a soft leather strap, similar to a bridle rein, should be attached to a stud or buckle on upper and outer edge of appliance, then brought round the body and crossed so as to form a figure-of-eight over hip of side affected, and also fastened to a separate buckle attached to elastic band. By this means the great drawback of most appliances, i. e., the tendency to slip down, is effectually prevented. With this appliance on, the patient is made quite comfortable and could almost at once commence riding.

27. **Enucleation of Prostate.**—Thomson reports on 18 cases in which the prostate was removed by the suprapubic method. The ages of the patients varied from 53 to 76. There were five deaths in this series. One was due to ether bronchitis and occurred in a patient 75 years old, who also suffered from mitral disease. Another man died 14 days after operation from a suddenly developed peritonitis. The third death was due to sepsis and occurred within 24 hours. Another patient died 12 weeks after operation from gangrene of the right lung. The last death was due to a pelvic cellulitis.

32. **Wryneck from Otitis.**—Leroux reviews the history of torticollis resulting from some lesion in the ear or complications, since Gellé first called attention, in 1894, to its possibility. In many cases the torticollis is due to neuritis of the spinal accessory nerve, as he had occasion personally to observe in 2 patients. After a suppurative otitis, the sterno-cleido-mastoid and trapezius muscles showed signs of paralysis and atrophy. In tests in which wax was injected in the cadaver at the points where pus usually presents in a suppurative process in the ear, the spinal accessory nerve was always found encircled by the wax, showing the almost unavoidable involvement of this nerve in such a process. If examination fails to reveal signs of mastoid or glandular suppuration, thrombophlebitis of the jugular vein may be suspected, as the spinal accessory nerve almost forms part of the wall of this vein, or the torticollis may be traced to meningitis. In the absence of signs of any of the above, examination of the blood may reveal latent suppuration or an extradural abscess. When the torticollis is the only symptom observed, it suggests that the nerve is involved only in its cervical portion, and only the external branch. Laryngeal disturbances are liable when both branches are involved. In some cases the patient becomes deaf after or during torticollis without ever exhibiting any symptoms pointing to the ear. In others there are no ear symptoms, but suddenly violent cerebral symptoms follow the torticollis. In every case of wryneck careful examination should be made of the ear.

34. **Radioscopy of Infant's Stomach.**—Among the interesting findings reported was the lack of any time difference between the emptying of the stomach after ingestion of breast milk and of diluted cow's milk. The evacuation proceeds progressively, and with quantities between 80 and 175 c.c., requires from an hour and three-quarters to two hours before it is completed.

35. **Spoons for Medicines.**—Martinet suggests various ways in which physicians can be sure that their patients are getting uniform doses of medicine. Spoons vary widely in size and capacity and cause irregular dosage. A good remedy would be to prescribe only the amount needed for the 24 hours, to be taken in four portions. Graduated medicine glasses, he says, are inaccurate, for mechanical reasons, which he cites. He accepts as the best remedy the use of an inexpensive semi-spherical spoon, 3.82 cm. in diameter, to hold 15 c.c., the handle straight, the spoon to be made of aluminum or something of the kind, and to be presented by the druggist with each filled prescription.

36. **Aneurism of the Subclavian Artery.**—Savariaud reviews the results of operative treatment of aneurism of the subclavian artery during the last 20 years. Treatment differs as the aneurism is exclusively outside of the scalenus muscle, or partly inside and partly outside. In the latter case surgical

measures are too dangerous, as the ligature would have to be applied so close to the heart. The Brasdor technic of peripheral ligature, above and below the aneurism, is preferable. The mortality is nearly zero, while the remote results are often surprisingly excellent. Nine cases in which this treatment was applied all resulted in an operative cure, without any mishap. In 22 cases of extrascalenic aneurism, treated by incision, extirpation or ligature of the second or third part, there was only a single death for which the operation was in any way responsible. In 20 cases of extrascalenic and intrascalenic aneurism there were only 9 operative cures, with 3 recurrences and 8 deaths. Out of the total material of 56 cases in which an operation was attempted, there were 41 operative cures and 10 deaths. Gelatin treatment was unable to effect a permanent cure in the 4 cases in which it was tried. One patient was reported cured by the gelatin, and the case is handed down in the records as cured, although operative treatment was required later, and it figures also as a surgical case. The motor disturbances seemed to be aggravated by the gelatin in Savariaud's own case. Gelatin should be given a trial before surgical measures, without fail, as it certainly is harmless and has quite a number of improvements and cures to its credit. It is especially indicated when operative measures are liable to prove too serious, as, for instance, when the over two-thirds of the subclavian are involved. The details of the various cases are summarized.

38. **Fistulæ Following Gastric Ulcer.**—Patel and Leriche here give the particulars of 6 cases of gastrocutaneous fistula following an ulcer. If the fistula is located high, the discharge from it is intermittent and there is not much disturbance of the general health. Medical measures should be given a thorough trial, and if they fail the best treatment is by resection of the ulcer with suture of the stomach walls. When the fistula is located low, the discharge is practically continuous and the general health soon suffers. Resection and suture are inadmissible, the authors state, for obvious reasons, and palliative operations, such as duodenostomy and jejunostomy, are serious and insufficient. Direct suture should be attempted, although it does not always prove successful.

41. **Pylorogastrectomy for Cancer.**—Leriche gives a detailed description of the technic by which the duodenum is mobilized as a preliminary to resection of the stomach. The various steps of the operation are shown in 8 illustrations.

42. **Dislocation of the Wrist with Protrusion of Bones.**—Couteaud warns against amputation in such cases, as a mutilated hand is worth far more than an artificial one. Resection is better than amputation, and reduction alone is better still. Resection of the dislocated bones of the carpus is necessary, he states, and tardy resection of the bones of the wrist is the last resort. Protracted antiseptic baths are indispensable, with mobilization and massage at the earliest possible moment. Radiograms of patients treated on these principles show excellent healing without ankylosis.

43. **Total Resection of the Saphena.**—The first part of this article by Terrier and Alglave was reviewed on page 156. This part gives the history of 21 cases, with 35 illustrations. The technic includes the total resection of the saphenous veins in treatment of superficial varices and ulcers of the leg and thigh, sometimes of both legs. The results were extremely gratifying.

44. **Cancer of the Rectum.**—Du Pan reviews 123 cases of cancer of the rectum, treated by Kocher between 1873 and 1904. Of this number, 40 proved inoperable and only palliative measures were attempted, but 83 patients were treated by extirpation of the rectum. Kocher does not accept adhesion to the prostate as a true contraindication. About 41.67 per cent. of the patients—a total of 20—have had no signs of recurrence to date, but 5 have succumbed to an intercurrent affection and only 15 are alive at present, some of them 11 years after the operation. His proportion of long survivals is thus 25.75 per cent., while other European surgeons report only from 5 to 18 per cent., with the single exception of Hochenegg, who has 21 surviving out of 84, that is, 25 per cent. Kocher advises as the best technic that which includes fixation of the central stump to the anus with or without invagination in the peripheral stump denuded of its mucosa. The peritoneum should be carefully sutured, not tamponed nor drained. The after-treatment should be extremely solicitous, with constant supervision. At the slightest sign of infection, opening up the wound and irrigating give the best results. He ascribes his freedom from heart failures to the use of ether instead of chloroform. Local recurrence was observed only in 39.7 per cent., generally in the perirectal tissue. Recurrence operated on at once gave excellent results. One of the patients, a woman, is still in good health after fifteen years, although she has been operated on four times for recurrence. Frequent examination is necessary, as recurrences rapidly become inoperable. Metastasis in the liver occurred only by way of the veins, and only when gaping vessels were left into which the cancer cells could then find their way. Hemostasis should be immediate and as complete as possible, avoiding leaving any bone surface in the operative wound. Spontaneous metastasis in the liver was observed only when there had been some complication in the vascular system.

55 Nucleated Red Corpuscles.—Ueber kernhaltige rote Blutkörperchen und deren Entwicklung. C. S. Engel.

48. **Inflammation of Extradural tissue in Meningitis.**—Peters discusses this subject from various standpoints and expresses his conviction that the lesions are induced by toxins in the blood. Direct propagation of the lesions is much less probable.

49. **Surgical Traumatism and Facial Paralysis.**—Jacobsohn states that in the 6 cases of traumatic peripheral facial paralysis which he has encountered in the last few years, there was a history of an operation on the head in every instance. Köster has also reported 6 similar histories in 8 cases of traumatic facial paralysis. Jacobsohn reviews the experience of other surgeons in this line, and gives the particulars of 2 cases in which resection of the trigeminus was followed by tardy paralysis. In one case, at least, he thinks that the paralysis might have been avoided by more cautious technic. Harvey Cushing's modification of the Hartley-Krause technic for removal of the Gasserian ganglion he accepts as a great advance, rendering consecutive paralysis much less probable. Better still would be the avoidance of any operation if equally good results can be obtained by stretching the nerve. This should be given a thorough trial. If an operation is considered necessary, the surgeon should endeavor to refrain from cutting the branches of the facial nerve.

50. **Resection of Nasal Septum for Primary Tuberculosis.**—Onodi gives the particulars of a case of extensive primary tuberculous lesion in the nasal septum cured by radical excision. The clinical picture and exploratory excision spoke for cancer and the lesion was removed by opening the nasal cavity in the median line and turning back the soft parts, not attempting endonasal intervention. The patient shows no signs of recurrence or of a tuberculous affection elsewhere to date, more than a year since the intervention.

53. **Menstruation as Source of Infections and Intoxications.**—Riebold has been making a special study of various morbid manifestations liable to accompany menstruation. He regards it as extremely important in the pathogenesis of numerous febrile affections. He thinks that there is no doubt that the menstruating uterus may occasionally prove the source of infection for actual septic affections. Fever accompanying menstruation is by no means uncommon, and is the result of absorption of bacterial toxins or of products of decomposition through the menstruating genitalia. The action of toxins is also evident in the numerous affections of the skin and nerves which may be observed accompanying menstruation, such as erythema, urticaria, herpes zoster and neuralgias. Still more important is the fact that infection or intoxication from the menstruating genital organs is liable to induce various forms of rheumatic affections, including actual polyarthritis and cardiac affections of a rheumatic nature. The course of the acute menstrual articular rheumatism does not differ in any respect from the classic type except, possibly, in its unusual mildness in some cases. In 8 of the 15 cases observed only the joints of the feet were swollen and painful, and the rise in temperature was slight and transient. The heart was not perfectly sound in any of these 15 girls; in all a valvular defect was apparent, quite serious in some. The changes in the heart were severe, out of all proportion to the mildness of the rheumatic involvement of the joints. The experiences related, Riebold thinks, establish the fact that menstrual infection or intoxication of a rheumatic nature may be the insidious and unrecognized origin of a valvular affection. Some typical examples of this febrile menstrual rheumatoid affection and of septic menstrual fever are related in detail. The only source for the staphylococci found in the blood in one case reported must have been the menstruating uterus. As menstruation ceased the symptoms subsided. In such cases there was none of the usual leucocytosis during menstruation. These septic cases are rare but undoubtedly exist and may explain certain cases of "cryptogenic sepsis." Patients who have had two, three or more recurrences of the menstrual rheumatoid affection have been free from them in his experience when the vagina was regularly rinsed twice a day at least with some antiseptic fluid. This is especially necessary when an odor suggests a putrefactive process. Frequent careful cleansing of the external genitals is important in prophylaxis of all these morbid menstrual phenomena.

64. **Primary Tuberculous Infection in Monkeys.**—Ghedini reports various series of researches with experimental tuberculous infection of different *organs in monkeys. In all the* experiments the lymphatic system constantly played a predominant part in the diffusion of the infection from the primary focus throughout the organism, and especially to the lungs.

67. **Influence of Grippe on Other Infections.**—Livierato found that injection of the bacteria of grippe with other germs favored the proliferation of the latter. The toxins generated by the grippe bacteria lower the resisting powers or act in some other way that promotes the invasion and proliferation of other pathogenic micro-organisms. He found further that the toxins of grippe bacillus injected after the organism has already been invaded by an *infection having usually a protracted* course, has the effect of materially shortening the course of the latter.

69. **Cancer of the Stomach.**—In the first case described the only symptom to call attention to the stomach was occasional slight hematemesis. There were no digestive disturbances nor pains in the stomach and the appetite was good. The pyloric region was slightly tender on pressure. The patient was a man of 56 and he suddenly succumbed with signs of perforation. Autopsy revealed a perforated cancer of the pyloric region. In the second case a man of 40 had suffered for some time from dyspeptic disturbances and gastralgia when acute rapidly fatal ileus developed. Autopsy showed also in this case a cancer of the pyloric region which might have been successfully removed if the warning of the recurring gastralgia had been heeded in time. No tumor could be palpated in either of these cases.

74. **Amputation of Breast.**—Tansini has modified the technic he recommended in 1895, to prevent necrosis of any part of the flap. By cutting the flap so as to include important arteries in the base, there is no danger of necrosis. The pedicle must be 6 or 7 cm. in diameter, and its center should coincide with a point 3 cm. from the posterior axillary line, 5 cm. from the spine of the scapula and 10 cm. from its angle. The flap is an elongated oval, slanting from above downward toward the median line of the back. The anterior margin of the flap starts at the end of the incision where it reaches the axilla, and this anterior margin is sutured to the anterior margin of the defect. The flap contains arteries which insure its nourishment. The technic is illustrated.

76. **Plastic Operations on Bladder.**—Baldassari advocates a technic which has proved very successful in experimental work on dogs. When a small defect in the bladder wall has to be covered he takes a corresponding flap from the bladder wall

itself near by. The flap contains a layer of serosa and a muscular layer, leaving the muscular layer exposed, but this gap can easily be covered by taking up a fold in the bladder wall, freshening the edges if necessary. The muscular layer is split where the flap is cut, leaving the half united with the mucosa intact, and cutting the pedunculated flap out of the other half of the muscular layer with the serosa on its outer side. The pedunculated flap is then drawn over the defect and sutured in place, and the omentum is caught lightly above with a few stitches.

82. **Delirium and Death During Convalescence from Ileus.**—In order to prevent absorption of toxins during recovery from intestinal occlusion, Capasso urges the necessity of purgatives, preferably oil, to free the intestine of foci of intoxication from retained fecal matter. Saline injections, intravenous or subcutaneous, should also be used to help cleanse the organism by "lavage of the blood."

83. **Typhoid Diagnosticum.**—De Rossi announced some time ago that the agglutination test is more sensitive if the cultures of the typhoid or other bacilli are first heated to 60 C. for an hour. A bouillon culture, kept for 24 to 48 hours at a temperature of 27 C., is distributed in test tubes which are fused and heated to 58 or 60 C.—no higher—and kept at this oint for one hour. Bacilli thus treated keep perfectly for ne agglutination test at any time, and the findings are more delicate than with live bacilli, either with the typhoid bacillus, *Bacillus subtilis*, *Bacillus pyocyaneus* or the *Staphylococcus albus*.

85. **Tendon Grafting for Strabismus.**—Monzardo describes his technic for correcting squint due to paralysis of one or more of the muscles of the eye. The principle is the same as in tendon transplantation in case of paralysis of the feet.

87. **Bladder Tuberculosis and Its Cure.**—Rovsing gives illustrations of specimens from some of the 56 cases of tuberculosis of the bladder that have passed through his hands. He also gives in a large picture an outline view of the kidneys, ureters and bladder in each case in miniature, grouping them all on a single plate, the tuberculous portions shaded, and each set marked with the initial letter of "recovery," "extirpation" or "carbolic treatment" as the case may be. In the female cases the outline of the uterus and adnexa is added to each set. It is an effectual method for graphic portrayal of the various conditions, for comparison both of the lesions and of the final outcome under carbolic acid treatment. Primary genital tuberculosis only exceptionally involves the bladder, he says, and it is a still rarer occurrence for the bladder to be alone or primarily affected with tuberculosis. As a rule, the bladder lesions have spread from a tuberculous affection of one or both kidneys. The only certain means of determining the condition of the kidneys is by catheterization of the uterus, and only then when the urine from one or both kidneys is found free from evidences of tuberculosis. Rovsing's cases show that a tuberculous lesion in the bladder may spread upward into the second ureter, toward the sound kidney. The urine from this ureter will then show signs of pus and tubercle bacilli when in reality the kidney beyond is still sound. In such cases, instead of abandoning the patient to his fate, as necessarily doomed by a bilateral tuberculous affection of the kidneys, a double exploratory lumbar incision, with possibly ureterostomy, may reveal that one kidney is still sound, so that its mate can be safely removed, after which the tuberculous lesions in the bladder and ureters are liable to heal spontaneously, if not too advanced. In the advanced and extensive cases, he advises treatment with carbolic acid, which he has found very effectual, having completely cured 13 patients by this means. After the bladder has been cleansed of pus he injects 50 c.c. of a 6 per cent. solution of carbolic acid, warmed to about 35 C. The fluid is retained for three or four minutes and then evacuated, when it flows out, muddy or milky. This procedure is repeated three or four times until the fluid comes away somewhat clear. The whole procedure requires only about ten or twelve minutes. The carbolic acid solution is drawn out from the bladder through a catheter, but the bladder is not rinsed afterward. A suppository containing 2 cg. of morphin is introduced into the rectum immediately after the injection, to deaden the pain which is liable to be quite severe for two or three hours after the treatment. Treatment at first—until the urine of the intervening day becomes nearly clear—is repeated every second day, later with longer intervals, and the cystoscopic findings are compared with the previous findings at first every week, then every fortnight and then each month. The results in his cases were that the tubercles subsided and the lesions healed, leaving a smooth white surface with a mother-of-pearl sheen. Rovsing thinks that the carbolic acid penetrates into the cells and interstices, following the same paths the tubercle bacilli have taken after their toxins have irritated the hyperemic mucosa of the bladder and thus produced conditions favoring the entrance of the bacilli into the bladder wall. A 6 per cent. aqueous solution of carbolic acid soon kills tubercle bacilli in the test tube, and its action in the bladder is probably enhanced by the hyperemia and phagocytosis which it induces. Be this as it may, one thing is certain, he says, namely, that for the first time a local treatment has shown itself capable of curing even very extensive and virulent tuberculosis of the bladder. He has never witnessed any serious by-effects. The urine was slightly discolored in some cases, and two little girls vomited a few times the next day. The only drawback is the pain liable to follow the injection, but this can be kept under control with a little morphin. The length of treatment varied from one to six months, according to the severity of the case. A radical cure is possible only when the bladder process is primary or when the primary focus in the kidney has been removed.

88. **Roentgen Treatment of Neuralgia.**—For four years Faber's patient had suffered from trigeminal neuralgia with two intervals of a few months' freedom from pain after resection of the inferior alveolar nerve and later of the mandibular nerve. As the neuralgia recurred with increased intensity and frequency, ten Roentgen exposures of ten minutes each were made of the upper half of the face within sixteen days. Improvement was evident at once and the patient was soon entirely free from pain. There has been no recurrence during the few months since. Faber remarks that it seems incredible that such an old and agonizing affection could be cured with merely five ten-minute exposures of the upper half of the patient's face, but such was the case.

Hygiea, Stockholm.

91. **Treatment of Epithelioma with Finsen Phototherapy.**—Schlasberg reviews his experience with 19 cases of cutaneous epithelioma treated by the Finsen technic with eminently favorable outcome. The results were much better and prompter when the growth was thoroughly curetted beforehand, and this

combination of curettement and Finsen phototherapy he regards as a distinct advance. It is free from the possible unpleasant by-effects of Roentgen treatment, while it seems to be fully as effectual at least. The prospects are better the less extensive and the more circumscribed and superficial the growth. If the glands in the region are swollen, the epithelioma has probably burrowed too deep for its ramifications to be reached by the rays. The variety of the epithelioma does not seem to influence the results of treatment, with the possible exception of nevus epithelioma. The cure was complete in 14 out of the 19 cases, although a repetition of the treatment for recurrence was required in 2 cases. From 2 to 30 or more exposures were given, but the number was much smaller in the cases with the preliminary curettement. He has not been able to find any record that Finsen or others adopted this combination.

95. **Influence of Goiter on Growth.**—Holmgren examined 17 patients with goiter, mostly of the exophthalmic type, and noticed that all were above the average height for their years. He found further that the epiphyseal cartilage became united at an earlier age than customary, and yet the body grew so rapidly that such persons were unusually tall. He has never heard this fact mentioned, and yet it completes the modern assumption of the functions of the thyroid gland, especially the hyperfunctioning in exophthalmic goiter.

96. **Simple Test for Chlorids in Urine.**—Ekehorn has devised a chlorometer which he has found very simple and practical for daily use by the busy physician. A test-tube about 14 mm. in diameter and 23 cm. long is graduated as follows: The bottom of the tube is marked off for a space to hold 2 c.c. This is labeled U and contains the urine. A space of 1 c.c. above is labeled I for the indicator. The third line corresponds to another c.c. and is marked zero. Above this the tube is graduated to correspond to each additional c.c. up to 15 c.c. He has two reagents, similar to Volhard's method. The first reagent is a solution of iron sulphocyanid; the second is a solution of silver nitrate. The formula for the sulphocyanid is 0.332 gm. potassium sulphocyanid in 40 c.c. distilled water with a saturated solution of sulphate of iron, free from chlorin, to make 100 c.c. The formula for the silver solution is 5.815 gm. silver nitrate; 50 c.c. of nitric acid, free from chlorin, and of a specific gravity of 1.2, and distilled water to make 1,000 c.c. The amounts of the sulphocyanid and of the silver must be equivalent in the quantities taken. Urine to the 2 cm. mark is first dropped into the test-tube from a pipette. The sulphocyanid reagent is then added to the line I, then the silver solution is added, and the tube is corked and shaken from time to time, until the color reaction occurs. The fluid assumes a grayish-white aspect as it loses the tint of the sulphocyanid. When this has happened, the line corresponding to the upper limit of the fluid represents the proportion of sodium chlorid per thousand. Albumin in the urine must first be coagulated by heating. The method is similar to Volhard's, only the nitrate of silver solution is five times weaker than with the Volhard technic.

97. **Traumatic Glaucoma.**—Stalberg reviews 6 cases from the literature and reports one personally observed in which glaucoma developed after an accident accompanied by considerable emotion or nervous strain.

99. **Scoliosis the Result of Asymmetrical Growth.**—Silfverskiöld has had occasion to examine 3,234 girls in the Gothenburg schools and found scoliosis in 416, that is, in 12.8 per cent. To his surprise, none of the factors usually incriminated in the etiology of scoliosis could be detected in many of the cases, and none common to all. The largest proportion of cases occurred in apparently robust girls of 15 and 16. More careful physical examination of 50 girls with scoliosis revealed an unsuspected asymmetry in development which, he thinks, is probably responsible in large measure for the scoliosis. The right leg was found a little longer than its mate in 37 out of the 50 girls, and the left leg longer in 8; that is, in 90 per cent. of the 50 girls inspected one leg was appreciably longer than the other. The difference varied in different children, being seldom more than 1 cm. In one child the left femur was found to be 0.5 cm. and the left tibia 1 cm. longer than the right. As the children developed into symmetrical growth the scoliosis vanished as a rule. His findings suggest the importance of early detection of asymmetry in development and its correction by extra thick soles and heels, as a means of warding off or curing scoliosis. Orthopedic measures may prove useful as adjuvants, but correction of the asymmetry is the main point in treatment in the majority of cases if not in all. It is possible, he adds, that there may be asymmetry in internal structures beyond our power to detect at present.

100. **Motor Neuroses Treated with Hypnotism.**—Six cases of convulsions or tics are described, not relieved by any treatment until daily seances of hypnotism were inaugurated, when improvement promptly followed. The patients were girls between 11 and 17. In the first case the spasmodic contractions occurred in the face, but, in different groups of muscles at different times. They were first noticed in infancy and had always been severe, not choreiform. After ten daily seances of hypnotism, in 1902, the tic was much reduced and had entirely subsided by the eighteenth sitting. The contractions recurred several times afterward in a mild form, but [illegible]e promptly met with renewed treatment, and after several b[illegible] courses the patient has been permanently free from ser[illegible] trouble since January, 1905, although a slight tendency to [illegible] tic still persists and will probably never be entirely eradi[illegible] The father had been mentally unsound and the mother sho[illegible]ne signs of tabes. The patient in the second case was a feeble[illegible]minded girl of 17, who stammered very much, blushed deeply at the slightest cause, and made involuntary movements with the right arm and leg—an actual and severe tic—whenever she began to speak. The effect of some brief courses of hypnotism was striking, especially as there were no indications of hysteria. In the other cases there was a suspicion of hysteria or of chorea minor. The benefit in a case of chronic chorea was so pronounced that a trial of hypnotism in all chronic cases is urged by Geijerstam. Five seances induced great improvement, and a complete cure was realized after 20 more, with no recurrence during the four years since. One patient was a woman of 27 with severe neurasthenic tremor from childhood, a brother also presenting the same tremor. She improved very much after 25 seances, the improvement progressing after 25 more, although slight traces of the tremor still persist. The hypnosis was applied in the different cases until profound hypotaxis was induced, occasionally with amnesia.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

GALLSTONES AND GALL-BLADDER DISEASES FROM THE STANDPOINT OF THE PHYSICIAN.

NORMAN BRIDGE, M.D.
LOS ANGELES, CAL.

These diseases are common, and they usually come first to the knowledge of the physician. He first prescribes for them and sometimes studies them; frequently he makes a diagnosis.

Whether or not he appreciates their character, he has for them a large measure of responsibility which he can not escape. If he believes a given case has become a subject for surgery, he is responsible to the patient that the consultant shall be capable, that he has the skill in surgical technic to do successfully the several steps of an operation; and, far more important, that he has the knowledge of pathology that fits one to deal with unexpected surgical conditions. The physician may recall cases in which a surgeon has found such conditions and, never having considered their possibility, has blundered in a nonchalant sort of way, to the harm of the patient and the regret of all concerned.

Then occasionally the physician finds the surgeon timid and unwilling to do an operation which, the former thinks, is demanded. This is not a fanciful picture, but actually occurs, and it is a very grave, as well as an embarrassing situation. Equally with the surgeon, even more than he, the physician is responsible both for the diagnosis and treatment of these cases. He can not hide behind his ignorance of their pathology and surgery by pleading that the surgeon knows about them better than he. Such a plea deserves opprobrium.

Further, the physician can often present the urgency of an operation to the patient better than the surgeon. Most people dread operations, and many suspect the surgeons of having undue enjoyment in operating and of being biased by visions of money. For these reasons the physician is a more acceptable counselor; but even he, in these days, is not free from the suspicion of seeking a part of the surgeon's fee.

SYMPTOMATOLOGY.

Every case must have initial medical consideration, as every one requires medical treatment, whether or not it ever comes to operation. Although the symptomatology is now fairly well understood, conditions arise now and then that are decidedly puzzling.

No doubt the chief beginning symptoms of gall-tract trouble have for long been attributed to the stomach. Gastralgia was formerly a very common disorder: now it is properly passing as a frequent pathologic entity. Most cases of pain in the bile tracts are still called gastralgia by a majority of medical men. It is only the sudden, awful colic in the right epigastric region (usually so intense as to require morphin) that is yet widely regarded as true hepatic colic, but the attacks of milder pain occurring periodically are nearly as certain to be in the hepatic structures.

It is substantially true that colic is always the result of muscular spasm, and in the bile tracts it is generally due to the grasp of a stone, the colic ceasing when the spasm relaxes, and the stone perhaps falls back or forward into a larger cavity. Stones not in the grasp of contracting fibers rarely, if ever, cause true colic. Pains from the ulceration of stones are usually long continued and rarely attended with spasm, while they are often attended with fever and other evidences of sepsis.

But colic may be due to spasm of other muscles besides those in the gall tracts, and we are in danger of going too far in the current generalization, for we must remember that there are gastric pains from ulcer, irritation by stomach contents, and even from distension. These may cause pains closely simulating the hepatic colic. The following case is illustrative:

Case 1.—A girl, aged 25, was seized with sudden intense epigastric pain, closely resembling gallstone spasm. It fluctuated, was worse and better every few minutes. She had been treated for stomach trouble and had lived on a restricted diet for some time. She had eaten a rather hearty meal three hours before, the pains having begun two hours after the meal. The stomach was found globular, and distinctly palpable at the moment of severest pain, less so as the suffering grew less. The pulse and temperature were normal. An attempt to pass the stomach tube led to prompt vomiting of a large quantity of undigested food, consisting mostly of prunes. The pain ceased immediately and did not return for two months, during which time the patient was under observation.

This was undoubtedly a pure case of gastric pain, due to spasmodic contractions of the stomach in its effort to evacuate its irritating contents through a spasmodically closed pylorus. Yet, in the absence of palpation, it strongly simulated the common gallstone colic.

But a similar experience of relief of epigastric pain from evacuation of the stomach contents obtains in true hepatic colic, and a lull in the suffering is, therefore, no proof of the disappearance of the whole cause of the pain. The causation of hepatic colic by overloading the stomach or by sudden indigestion is so common that prompt evacuation of the stomach is usually in order. The following case is in point:

Case 2.—Mrs. B., aged 50, had for 4 days occasional slight discomfort in the epigastric region. It had once or twice awakened her at night and kept her awake for half an hour. Then severe pain came on with little or no tenderness and no fever. The pain fluctuated but little. Zinc sulphate, 20 grains, promptly brought up a lot of spinach and liquids, with marked although not complete, relief. Then a dose of morphin gave absolute relief, which continued three days. No fever followed, and after a restricted diet for two days she began to eat more freely, when pain of a severe, although not a terrible character, came on, which was nearly continuous for a day, when she vomited a large amount of macerated asparagus tips with prompt relief of pain. But the pain soon returned, lasting another day, when it suddenly ceased. A single small gallstone was found in the stools a day after the subsidence of the pain. During this last attack there appeared slight but distinct tenderness over the gall bladder and a little jaundice the last day or two. Temperature was 101 at times. There was a slight leucocytosis (8,000 whites) at the height of the pain.

Pains below the scapula (right most often) and about the sternum probably do result from irritation of the bile ducts due to stones and otherwise, but, to my mind, they are unreliable as a guiding symptom; at best they corroborate other and more positive indications of biliary trouble. Many a physician has been led by ordinary chest-wall neuralgias, when unsupported by other evidence, to a false diagnosis of hepatic disease. Probably, too, some have ignored these pains when they have been reflex and due to gall-tract trouble.

After the pain, the most important symptom is tenderness over the gall bladder, found best by deep steady pressure, while the respirations move the organ against the fingers, and by sharp percussion over this region at the moment of full inspiration. Then come chills and fever, perhaps very irreguarly, and leucocytosis, with possible jaundice, although this last is never proof of infection. Palpability of the gall bladder and enlargement of the liver may be urgent evidence, and local peritonitis is most urgent of all. The evident peril of the patient depends on the degree of these signs and symptoms; that is, the general evidence of infection from the hepatic region. The hidden peril depends on the uncertainty as to exactly what may be going on behind the wall of the abdomen. Pain is not *per se* evidence of peril, infection is, and this often comes indirectly from the thing that provokes the pain. As to some of these perils we may profitably review our past experiences for instructive, as well as surprising, lessons, particularly our work during the years when we were not thinking of the gall bladder as a large factor in the pathology of the abdomen.

There is certainly one class of gall-bladder affections that has been almost universally misunderstood. Such are certain chronic ones, with profound chills and fever, occurring in an irregular, erratic manner, extending over years of time, often with long intervals of quiescence and with almost no local or focal signs. The following remarkable case[1] illustrates what is meant:

Case 3.—Mr. C., widower, aged 77, well preserved and plump, had lived a regular and moderate life of office business. For fifteen years he had had an occasional sudden attack of chill and high fever. A profound chill would be followed by high temperature for a few hours; then a profuse perspiration. The next day he would feel well and might so continue for six months before another attack. Sometimes he thought the attacks were provoked by slight indiscretions in diet; he was never guilty of a great indiscretion. They grew more frequent with the years.

Course of Disease.—During the winter of 1900-1901, while sojourning in California, these attacks had become rather frequent, coming as often as once a week, then two or three times a week. In some of them he was slightly delirious. An attack lasted about 6 hours and the temperature often reached 104. He now began to feel greatly prostrated for some hours after an attack. The chill would come without any regularity as to time, although it came oftener in the afternoon or evening. There was no pain or tenderness, that he was conscious of, in any part of the body, either during the attacks or between them. The intervals were without fever.

He lost 20 to 30 pounds in weight within 6 months and was growing progressively weak. There was very trifling tenderness beneath the right costal arch, elicited by deep pressure and manipulation, and no other sign of disease. Digestion was fair, bowels were regular, or a trifle constipated, and the urine contained a few hyaline casts, but no albumin, and the solid output was nearly up to the normal. The blood showed no malarial organisms during an attack and there was slight leucocytosis (8,500 whites).

Operation.—Operation revealed a gall bladder contracted to the size of the end of a small finger and, of course, situated deep in the abdomen. Its walls were very thick and the gall-bladder site of the liver was covered with considerable fibrous tissue, evidently the result of chronic inflammation. The viscus itself was found filled with a mucoid material, without a stone. A drainage tube was fastened at the opening of the gall bladder and kept there for several weeks, when it was forced out by the healing of the sinus from the bottom.

The first week after the operations there were two slight chills, followed by a temperature of 101, lasting but a short time. Thereafter, and up to last report, which was April, 1906, no symptoms of his old trouble have appeared. The operation seems to have effected a complete cure. Unfortunately, it was not possible to make a bacteriologic culture from the contents of the gall bladder.

Another case had a similarly contracted gall bladder, without chills and fever, but with years of frequent sharp attacks of diarrhea:

Case 4.—Miss M., aged 26, gave a history of several severe paroxysms of epigastric colic, some 5 or 6 years before. They were without known fever or jaundice, and left no symptoms the patient was conscious of. Later she had periodic attacks of diarrhea that was substantially rebellious to all treatment. This trouble lasted three years or more. Then developed suddenly a localized peritonitis about the gall bladder, with fever and great tenderness. Under medical treatment the acute symptoms subsided, but there was deep tenderness and slight fever remaining a month later, when the case was operated on by Dr. Murphy. A gall bladder, much contracted, thickened and retracted, was found full of pus, and without a stone. It was drained; and it recovered with a complete subsidence of the attacks of diarrhea.

In this case, like the previous one, there was fibrosis about the gall bladder and about its usual place against the liver, showing chronic inflammation to have existed for a long time. In this case diarrhea was as mysterious as the chills and fever in the previous one. Both were clearly produced by gall-bladder disease.

That such cases as these must come to be better studied and given surgical relief earlier goes without saying, and the responsibility lies almost solely with the physician. They constitute his opportunity and his duty. Such cases are numerous in every community, and every physician of large experience has the dubious pleasure of recalling instances of temporizing neglect or complete failure to appreciate what, in the light of present-day knowledge, were very evident gall-bladder cases that projected themselves before him with proof that now seems as plain as day. But he was blind and deaf.

I must mention another case that vividly illustrates the long continuance of gall-bladder symptoms without recognition:

Case 5.—Mr. A., aged about 54, had had for about a dozen years, occasional seizures of intense epigastric pain, lasting one to six hours, and often ending in vomiting. Morphin injections were often required. The attacks nearly always followed a hearty meal of rather indigestible food. Many times the pain was distinctly to the right of the mesial line. Sometimes there was tenderness for some days after an attack. Only once or twice had there been jaundice and then only for a brief time.

---

[1] This case has already been partially reported by Dr. J. B. Murphy who preformed the operation.

I saw the patient, in consultation with a friend (to whom the case was also new), a day after an attack began. Then a localized peritonitis about and below the gall bladder was demonstrable. Fever, tenderness, and constant pain were present, with rapid, weak pulse, and general evidence of desperate sickness. There was no jaundice. It was supposable that a rupture of the gall bladder (or of the stomach at the site of an ulcer), had occurred to produce the peritonitis. The situation precluded the possibility of even an effort at surgical relief and the man died the next day. The postmortem showed a normal stomach, a large gall bladder, partially collapsed, a half inch of its fundus being folded over on itself, and a plastic peritonitis over a space about and below it of 6 by 8 inches. This region was slightly bile-stained near the gall bladder. The gall bladder had evidently leaked from distension, but no gross rupture was discoverable. The contents consisted of mucoid material and a little bile. The cystic duct was not patulous. There can be no doubt that for many days before this attack, the enlarged gall bladder and the urgent need of surgery could have been easily discovered by the most casual examination.

The true significance of enlarged or distended gall bladder is often missed, especially in the presence of jaundice. Long-continued jaundice with large gall bladder rarely means stone, while such jaundice with no distension of the gall bladder means stone with probably more than 80 per cent. of certainty. Long-continued jaundice with distended gall bladder signifies, with a very large percentage of certainty, some tumor obstructing the common duct. Such tumor may be in the pancreas, liver or intestine, and is likely to be malignant. With the distension of gall bladder may come also considerable enlargement of the liver as a whole, without pain or tenderness and without irregularity of its surface such as is often present in carcinoma.

SURGICAL TREATMENT.

Whether operation ought to be done in all cases of proven gallstones or of suppuration or distension of the gall bladder is the same question over again of the misfortunes of the appendix. Patients recover or become quiescent, remain so for years (even with gallstones), and die of other diseases or of old age. Hence one camp of doctors contends that in all such cases we should not operate until forced to by the most exigent conditions. The other camp says that, for the sake of safety, operating should always be done and usually done promptly, since the next attack might be fatal. Both are in part right; neither can prove the other wholly wrong. The unknowable elements of the subject, which are of the nature of a game of chance, that permit so many patients to wait and never come to great harm and that tempt doubters to say, as to some patients operated on, that possibly they might have recovered or become quiescent without operation if they had waited; and that send so many waiting patients to death in surprising ways, who apparently might have been saved by timely and proper operations; these uncertainties put off, and will continue to put off, the day of final, complete agreement among the profession about this class of cases.

One of the elements referred to is the utter impossibility of ever knowing the exact pathologic state until the body is opened; another is the indeterminate measure of the physiologic resisting power of the particular patient until after he is dead.

The fact is that, with gall-bladder infection proved, whoever waits for an operation takes some risk of his life, for he can not know that a hidden avenue of fatal infection is not being formed. It is the right of any responsible person to take that risk if he likes, whatever the hazard may be; and in some cases the hazard does not seem to be much. Certainly the mere presence of stones without infection is not dangerous *per se;* it is the uncertainty as to when the stones may start an infection that constitutes the menace. But a sudden profound chill followed by high fever of short duration, and then by profuse perspiration, are not necessarily proof of an infection that puts life in imminent peril, unless there are also the local signs of a severe character, such as great tenderness, pain and swelling. Case 3 is proof of this proposition.

People are taking great personal risks in manifold ways all their lives and with the lightest thought. But if one suffering from cholelithiasis, to the extent of producing marked symptoms, would minimize to the lowest point his danger of death from it, he probably will have it dealt with surgically; always provided he has a surgeon who is wise in pathology and procedure, as well as expert in technic, and provided he, the patient, has good vital organs. That general statement is still true of the diseased appendix; it is true of gallstones and gall-bladder infection as well.

All cases of chronic cholelithiasis in which the suffering has led to the opium habit should be operated on. Every case of known distension of the gall bladder by fluid of any sort is in constant peril and should be operated on if possible. If there is reason to believe that the bladder contains pus, operation is urgently demanded. And in all cases in which frequent recurrences or the persistence of symptoms indicate the progressive contraction and fibrosis of the gall bladder operation should be insisted on, for in these there is some danger of an explosion of infection that may destroy life and a certainty of the disease getting worse and not better. An operation in the absence of urgent infection (after an attack is over, the so-called "interval"), supposing good vital organs and a good surgeon, is almost devoid of danger; a small fraction of 1 per cent. of mortality.

MEDICAL TREATMENT.

All cases of proven gallstone or gall-bladder trouble are proper subjects for surgical consideration, whether they are to be regarded as surgical cases or ever come to operation. Whether operation is to be done or not, when conditions do not sound the insistent need of an operation, or the patient declines, or the physician sees reasons against an operation, proper medical treatment should be instituted always, and persistently carried out. This is as true of the gallstone troubles as it is of those of the appendix.

What are such measures? In the acute cases there should be absolute rest of the body. Rest of the stomach and bowels to the extent of starvation for some days is best, especially where peritonitis is present or threatened. Nutrient enemas may be allowed tentatively, but never nutrition by the stomach in such cases. The upper abdominal organs must be kept still; not shaken about by peristaltic movements. During the initial pain it is always best to evacuate the stomach promptly, and for this purpose an emetic of sulphate of zinc is perhaps better than the stomach tube, since it tends to relax spasm and often evacuates food contents that could not pass through a tube. Enemas are best to evacuate the bowels in the acute cases. After starvation begins, the bowels accumulate little fecal matter and give little trouble. General measures to sustain the powers of life, as nutrient enemas and perhaps hypodermics of strychnin, are always in order after a few days of the starvation. Perhaps there is some benefit to be expected from hot poultices or ice bags over the epigastrium. It is much to be regretted that our views of the exact effect and value of these measures should not be more settled and unanimous than they are; some of us prize the hot applications, some use the cold, while others deny the value of either.

In the subacute and chronic cases the daily full flushing of the bowels by alkaline laxative waters is useful, but it is irrational to suppose that gallstones are thus washed away. Nor do olive oil or any other of the pretended expulsive agents have the smallest effect. The thing that happens is probably merely the elimination of effete matter from the body, thus increasing the physiologic resisting power. This process is aided by a restricted diet of the most proper foods and by general good hygiene. It is the custom in Europe to send patients with chronic gall-tract diseases to some of the spas (mostly to Carlsbad) for a course of the waters, to see if an operation can be avoided by the appearances of recovery. These measures are all useful, for the patient gets the benefit of an abstemious regimen, for a time at least, in addition to the waters, and thus is frequently able to improve in a marked manner.

To go to the springs, drink freely of water and live on a low diet, be much out of doors, and rest from work and perhaps from cares is always wholesome for these cases. Such a vacation can be taken once or twice a year with great propriety, but it has little power to postpone the day of a final surgical operation or death, if, on returning home, the patient goes back to his former habits of overfeeding, irritation of stomach, lack of depuration, and generally unhygienic life. This latter is just what a large number of patients are constantly doing. By this course they invite infection from irritating things in their gall tracts and so hasten surgical intervention. This last is no misfortune if the surgery can be done at the right time and under the best conditions; but they usually regard it as a misfortune and think they are fighting it off by their occasional water cures.

The only proper course for such patients, who would be fairly well and avoid surgery, is to live lives of absolute regularity and abstemiousness, rigidly temperate in everything except the use of water, and hygienic and moderate in every day's living. One day of overdoing, overeating or overdrinking, or of severe chilling of the body, may start an infection and precipitate an acute attack that will destroy life unless prevented by timely surgery.

If a chronic gallstone patient who refuses surgery wishes to manage his health in the usual erratic manner and so make an operation or death certain, it is perhaps his privilege as a citizen to do so. But it is only common fairness that he should know the inevitable tendency of his ways, and it is for the physician to show him this and to point out a wiser course, and then leave the responsibility with the patient, where it really belongs.

Operative Treatment of Lung Cavities.—According to J. Berry, in the *Clinical Journal*, June 6, 1906, incision and drainage constitute the only operation on lung cavities that is of practical importance. This is more feasible in cavities at the base than at the apex or deep seated in the lung. It is indicated in abscess where the results are good (mortality 20 per cent.) and in gangrene (mortality 35 per cent.). In bronchiectasis and tuberculosis the results are not encouraging. A patient with abscess due probably to the bursting of a liver abscess into the lung made a good recovery after operation.

NEPHROLITHIASIS.

A. H. CORDIER, M.D.
KANSAS CITY, MO.

In the searchlight of that greatest of all beacons, pathologic and surgical experience, new territory is being invaded and taken possession of by modern surgery, and fewer and less debatable grounds remain along the border line of internal medicine. In no locality is this better settled than in nephrolithiasis. Stones in the pelvis of the kidney or ureter, when known to exist, are looked on as dangerous foreign bodies and dealt with accordingly. Occupation, locality, or age does not, in my opinion, have any direct etiologic bearing on these cases. As a matter of fact, we do find more cases in persons between the ages of 20 and 50 years, but we find more people between these periods. I have found this condition to exist about equally in the two sexes. High living and sedentary habits are said to predispose to the formation of stones in the kidney, but my experience does not sustain this claim. The separation of the solids from the urine in the pelvis of the kidney gives rise to the condition known to the layman as "gravel" and produces only mild symptoms of mechanical irritation of the ureter, bladder and urethra. This condition may be transient, or it may lead to more serious stone formation by these little particles becoming agglutinated, by the presence of an infection, blood, mucus or pus, yet it is possible for a stone to form without the evidence of bacterial invasion or structural changes in the kidney. The nucleus of a stone may be composed of one salt of calcium, or uric acid, while the body of the calculus is made up of another. Carbonate of calcium stones are rare in man, and are deposited in alkaline urine, while the uric acid and oxalate of calcium are found to have their origin in acid urine. The chemistry of these cases, while very valuable and interesting from a scientific standpoint, is overshadowed by the diagnostic and surgical phases, to the busy practitioner and surgeon.

Oxalate of lime calculi are found most frequently, and usually produce the severer types of symptoms and pathology.

The right kidney, like other structures on the right side of the median line in the abdomen, is the one most frequently affected by stone, yet in rare instances both organs have calculi.

VALUE OF EARLY SURGERY.

To appreciate thoroughly the value of early surgery in these cases, one must understand the pathologic changes wrought by time in the ureter and kidney.

It is only a question of time in every case of renal calculi until an infection is developed, and, when once started, a nephritis is the result; if the ureter is occluded, dilatation of the pelvis takes place, and a pressure obliteration of the parenchyma is sure to follow unless quickly relieved. Perinephritic abscess, with extensive burrowing of the escaped fluids, takes place in some cases. The source of the infection may be from the bacteria in the blood, but usually is from an ascending ureteritis. A surprising number of infectious cases have their origin from the *Bacillus coli communis*, probably by direct invasion through an aseptic adhesion of the kidney to the ascending colon.

The number of stones and their sizes present a wide range, from one to dozens, from a mere speck of sand to a stone weighing many ounces.

I have found that the cases of uric acid stones, as a rule, have only one small, irregular, angular, speculated stone, while the oxalate of lime stones have been large, multiple stones, with roughened surfaces, taking the shape of the kidney pelvis and calices. The phosphatic variety is usually an irregular, friable, semi-mushy stone found in old suppurative cases (Fig. 1). The carbonate of calcium stone, a rare variety, is smooth, multiple, irregular and very hard, producing kidney structural changes only slowly.

The range in weight of stones removed in my own work has been from a few grains to nearly four ounces. The calculus, as a rule, is found in the pelvis of the kidney or in one of the calices, yet it is of no uncommon occurrence to find a good-sized stone imbedded in the parenchyma. These are the cases that so often give rise to postnephritic abscess. These imbedded stones are often overlooked at the time of the operation.

Morris estimates that both kidneys are affected in about 10 per cent. of the cases. In none of my cases have I found both organs with stones in them.

The uric acid and oxalate of calcium stones form more easily than the pasty, semi-solid, phosphatic deposits.

A small stone may pass from the kidney and give rise to no symptoms, and a very large calculus may be found as a surprise in the pelvis of the kidney at a postmortem. Several subjective symptoms may be absent in the presence of a stone easily palpable externally.

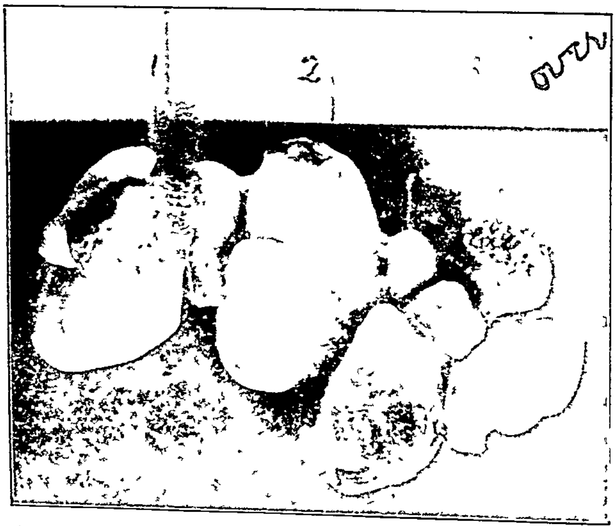

Fig 1.—Nephritic calculi, carbonate of calcium Weight, 1,540 grains.

A healthy kidney is sooner or later converted into a diseased one by harboring these foreign bodies. This change usually takes one of the three courses: Interstitial sclerosis, atrophic changes in parenchyma due to calculous hydronephrotic pressure or suppurative pyelonephritis, and rarely carcinoma or sarcoma as the result of chronic mechanical irritation. These pathologic changes have all shades of variation from a mild microscopic change to a complete destruction of the kidney with death of the patient from coma, amyloid changes in other organs, with a hectic accompaniment and death. While a stone remaining in the kidney is of much danger to that organ, the hazzard is materially increased if the calculus, in its endeavors to reach the bladder, becomes lodged in the ureter. A stone thus situated may cut its way out of the ureter and lead to urinary infiltration, or completely block the flow of urine from that kidney and destroy the functions of the organ by pressure of retained urine, or it may be the source of a calculous anuria by interfering with the function of the opposite organ. The persistence of pain is a matter of no small consequence in such a case.

DIAGNOSIS.

In making a diagnosis of stone in the kidney, it might be well for us always to remember that there are a number of other maladies producing symptoms misleading in character, and, again, a stone may exist without producing the typical stone history, or the symptoms may be manifested in a remote locality. We know that many obscure febrile symptoms are produced by a stone in the gall bladder; the same is true of nephrolithiasis. A stone that disturbs the surface epithelium and permits absorption may give rise to a urinary (septic) chill, the source of which may puzzle the diagnostician. I have seen a number of such cases.

If at a nephrolithotomy a large stone is found and there is a short symptomatic history, we all know that the stone was a long time forming; hence must have had a long quiescent period. I am firmly of the opinion that in such a case symptoms were present, but not correctly interpreted. The use of the microscope and the sifting of obscure evidence will often lead us to make a correct diagnosis where others have failed. Lumbago, a pain referred to the glans penis, or clitoris, increased desire to urinate, retraction of testicle, etc., all, as a rule, are sympathetic manifestations. A carefully compiled clinical history extending over a period of years will often clear the way to a correct deduction. An attack of pain in the side, or back, ten or fifteen years ago, may have been an attempt to expel a calculus that has remained quiescent in pelvis or kidney ever since, the patient being in danger all the time of the development of a suppurative process. Tenderness, as a symptom of renal calculi, is often absent, and too much reliance should not be placed on it. Tenderness, as a rule, is found only in those cases in which there exists a marked enlargement from inflammatory involvement of the kidney. Pain is present in the great majority of these cases. Of much diagnostic value is hematuria, as with few exceptions blood can be detected in the urine unless the ureter is completely occluded. In that event the presence of renal colic or pain, with an enlargement of the kidney, would aid in the diagnosis. The referred pains are often present during the passage of the stone along the ureter. The ilioinguinal, iliohypogastric and genitocrural are the nerves most frequently affected.

In renal colic the typical diagnostic symptoms will depend on the size and shape of the stone, as well as on its consistency and surface condition and on the elimination and nature of the attack, which lasts from a few minutes to several days, and disappears as suddenly as it appeared, the stones reaching the bladder or dropping back into the dilated pelvis of the kidney. These attacks may recur at any time, depending on the number of stones or the ability of any stone to block the ureter.

A feature that is noticeable in many cases is the increase of the pain and colicky spells from riding on a rough road. The pain during the passage of the stone is the most intense of any suffering and is usually accompanied by vomiting and profuse diaphoresis. If much blood or pus is present, a chemical test for albumin may be misleading unless the microscope be used also. Hyaline casts are found in a certain percentage of these cases and are evidence of stone irritation to kidney structure.

operation. On two or three occasions I have resorted to the use of rubber tubing carefully tightened about the pedicle of the kidney to limit the loss of blood. This will rarely be necessary.

After the stones have been removed, the kidney irrigated and the patency of the ureter established (if the case was not one of severe infection), the kidney may be closed as with any other wound, using chromicised gut for that purpose, taking care that the sutures do not go through the pelvis and thus act as a nucleus for further stone involvement. If it is a suppurating case the pelvis should be packed with gauze and a rubber drain put in. The gauze will aid in controlling the bleeding, especially if good firm pieces of gauze packing are put in around the kidney also. The wound is dressed in the usual way. This gauze should remain in place for several days, as a too early removal will induce a troublesome hemorrhage. Do not become discouraged at the duration of the drainage, as many of these old cases will drain for months, ultimately closing for good.

The removal of the kidney in any case is a matter that should receive very careful consideration. The indications for a nephrectomy are becoming fewer and rarer, as we understand the dangers of such a removal, and the recuperative powers of a crippled kidney if the source of irritation is removed.

When possible, the stone should always be removed through the parenchyma, as an incision into the upper ureter or pelvis will incur more risk in the development of an unhealed urinary fistula.

CONCLUSIONS.

1. Nephrolithiasis is more prevalent than is generally supposed.
2. A stone having formed in the pelvis of the kidney, if too large to pass, will sooner or later produce symptoms demanding its removal.
3. Suppuration in stone cases as a rule is a late process, and should be prevented by early surgical treatment.
4. There exists a special cause for stone development in the right kidney; 80 per cent. of my cases have occurred in the right kidney.
5. With a carefully obtained clinical history, the diagnosis of stone in the kidney is easy.
6. Obscure, persistent pains in the region of the kidney, in a patient who had a renal colic years ago, should lead to an exploration of the organ.
7. A wound in a healthy kidney heals quickly.
8. The operation of nephrolithotomy has a very low mortality.
9. Hemorrhage from a kidney is generally easily controlled.
10. At time of operation, the patency of the ureter should be established.
11. The kidney should not be removed if it has a patent ureter or unless it be practically destroyed by the disease.
12. Postoperative patience and faithful effort on the part of the surgeon, will result in the saving of many organs; otherwise removal will be necessary.

Typhoid Strumitis.—Inflammation of the goiter is described by Baradulin in a man 36 years of age who had had a goiter for 29 years. During the fourth week of typhoid fever an abscess developed in the right half of the goiter, which was opened, and bacteriologic examination revealed typhoid bacilli. —*Russky Vrach.* No. 14, 1906.

THE SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCER AND ITS RESULTS.*

WILLIAM J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

The contributions to the literature of ulcer of the stomach and duodenum have become so numerous that it will be impossible in a paper of this character to give credit for the many valuable advances which have been brought out by individual workers. I wish in this connection, however, to express my appreciation of their labors.

For more than twenty years the complications of this malady have received attention. Operations for benign stenosis of the pylorus and some acute secondary manifestations have occasionally been performed, but not until the last five years has there been a surgical invasion into the field of unhealed ulcers with a view of giving relief from pain, under-feeding and chronic disability which so frequently accompany the disease.

Acute ulcer of the stomach and duodenum properly belong to the domain of internal medicine, and surgery has to do only with the complications such as perforation, hemorrhage and obstruction.

The surgical treatment of acute perforations of the stomach and duodenum is now on a sound footing, the results depending on speedy diagnosis and prompt operative relief. Patients operated on within the first five hours usually recover; after ten hours the majority die. We have had 7 gastric with 2 deaths and 9 duodenal with 3 deaths.

Suture of the perforation and pelvic drainage with or without irrigation, the patient being subsequently maintained in the semi-sitting posture (exaggerated Fowler's) for several days, gives the best results.

One mooted point concerns whether or not a gastrojejunostomy shall be done at the same time, as a considerable percentage of patients following perforation will develop stricture, adhesion, or other deformity in the healing process. If the perforation lies in the duodenum or close to the pylorus it should be sutured transversely to avoid interference with the lumen of the part involved. Generally speaking, if it seems probable that stricture or other secondary condition will result and the patient is in good condition, gastrojejunostomy should be performed providing it can be done without spreading the already present infection. If in doubt, a living patient is better than a completed operation at a greatly enhanced risk.

Hemorrhage from the stomach occurs in two forms, acute and chronic. Recurring acute hemorrhages are best treated by opening up the stomach or duodenum, locating the bleeding point and suturing the part firmly with catgut on a curved needle from the inner (mucous) side. The outer surface is then exposed and protected over this area by a few mattress musculoperitoneal sutures of linen (modified Andrews method). We have not found gastrojejunostomy for acute hemorrhage a reliable procedure. Out of 6 cases we have had 1 patient bleed to death within two weeks after gastrojejunostomy and a second saved by opening up and securing the bleeding vessel, while 5 who have been treated by primary operation on the bleeding point with or without excision of the ulcer; all recovered.

---

* Read in the joint session of the Sections on Practice of Medicine and Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Chronic hemorrhages, on the contrary, can be cared for by gastrojejunostomy, especially if the ulcer is situated in the duodenum or near the pylorus. In a number of instances we have, however, excised the ulcer and closed the defect by plastic operation planned in such way as not to interfere with drainage by subsequent contraction. Several of these cases amounted to gastric resections with end-to-end suture.

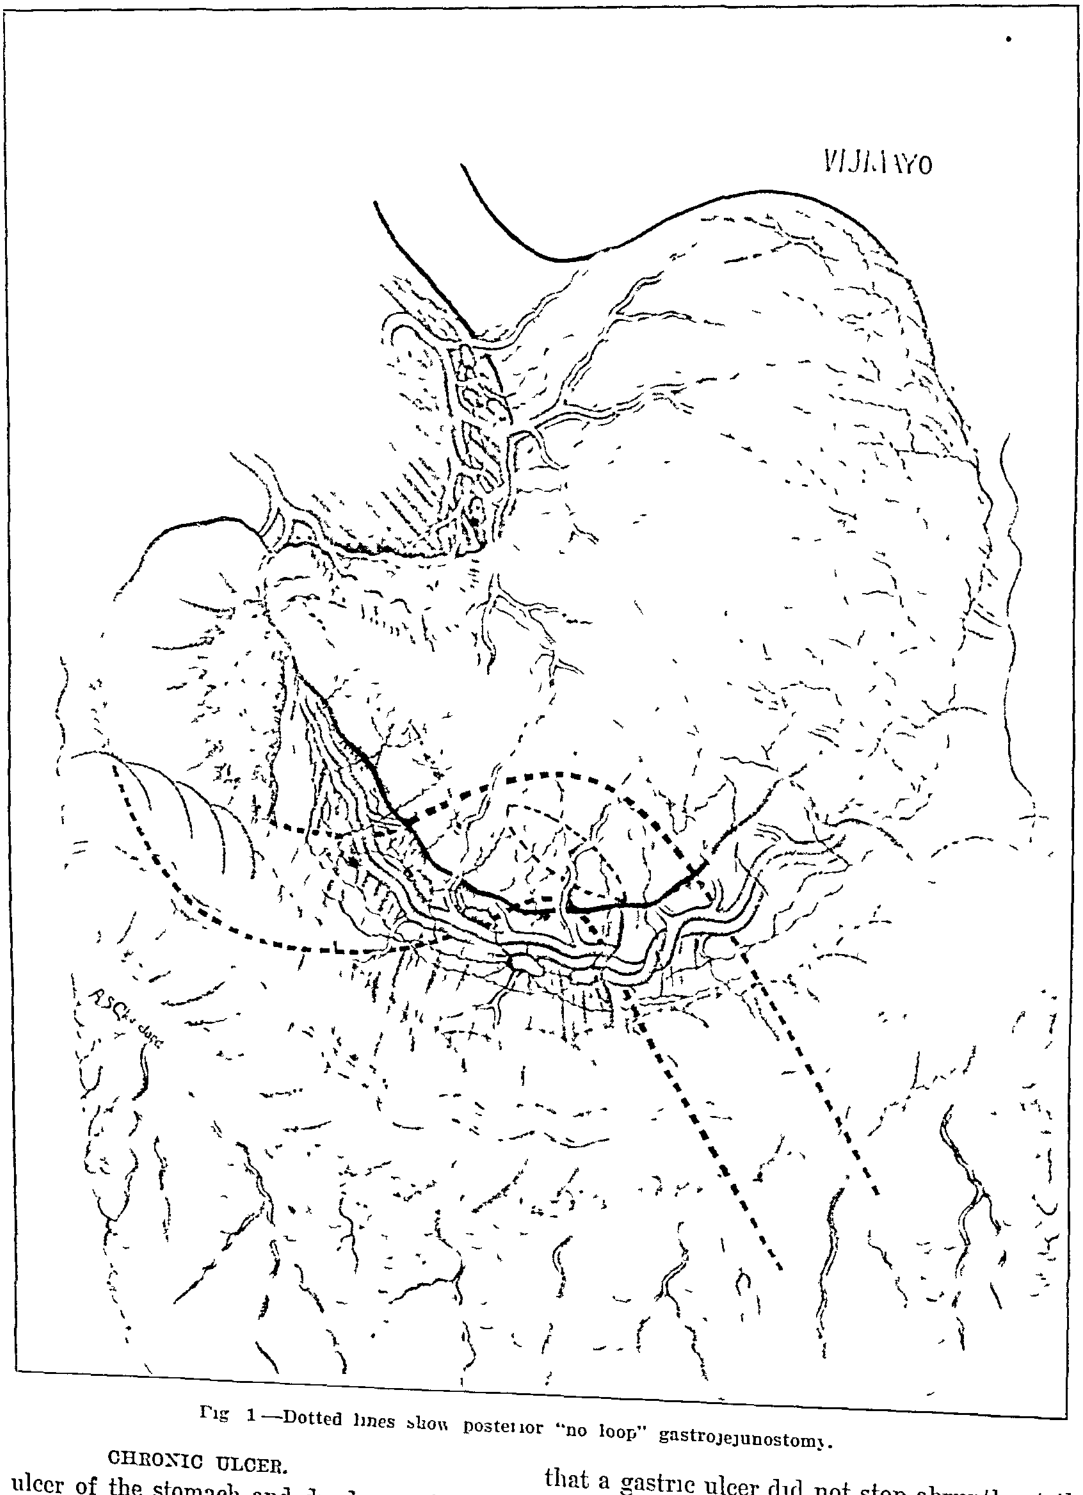

Fig 1—Dotted lines show posterior "no loop" gastrojejunostomy.

CHRONIC ULCER.

Chronic ulcer of the stomach and duodenum is most common in men and is essentially a disease of adult life. It entails years of invalidism on the victim and in fully 25 per cent. is the direct cause of death, while indirectly through anemia it permits of general infections, tubercular or otherwise, and thus doubles the mortality. Surgical interference should be considered when the failure of medical treatment is made manifest by a continuance of the symptoms or frequent relapses.

Our experience (W. J. and C. H. Mayo) covers 600 operated cases up to May 1, 1906, 436 stomach, 135 duodenal and 28 stomach and duodenum. In 46 classified as duodenal the duodenum was primarily at fault, the stomach being involved only at the pyloric ring. It was rare that a gastric ulcer did not stop abruptly at the pylorus.

Gastric ulcers were multiple in less than 15 per cent. of the indurated and estimated at about 20 per cent. of the mucous lesions. The most common form is the saddle ulcer of the lesser curvature above the pylorus extending flap-like down the anterior and posterior wall (prepyloric).

Duodenal ulcers involve the two inches immediately below the pylorus and extend up to within at least three-fourths of an inch of it. In all but 5 cases the bowel lesion was single.

Of the 163 duodenal ulcers, 77 per cent. were males and 23 per cent. females and in all but 7 cases the site of the ulceration was indurated, the thin intestinal wall enabling ready identification. In the stomach, on the contrary, the thick tissues sometimes prevented accurate localization of a mucous lesion, the proportion being 70 per cent. indurated and 30 per cent. non-indurated. Three of the acute hemorrhagic cases were of the mucous variety, while all but one of the acute perforations occurred through the scar of a partially healed ulceration.

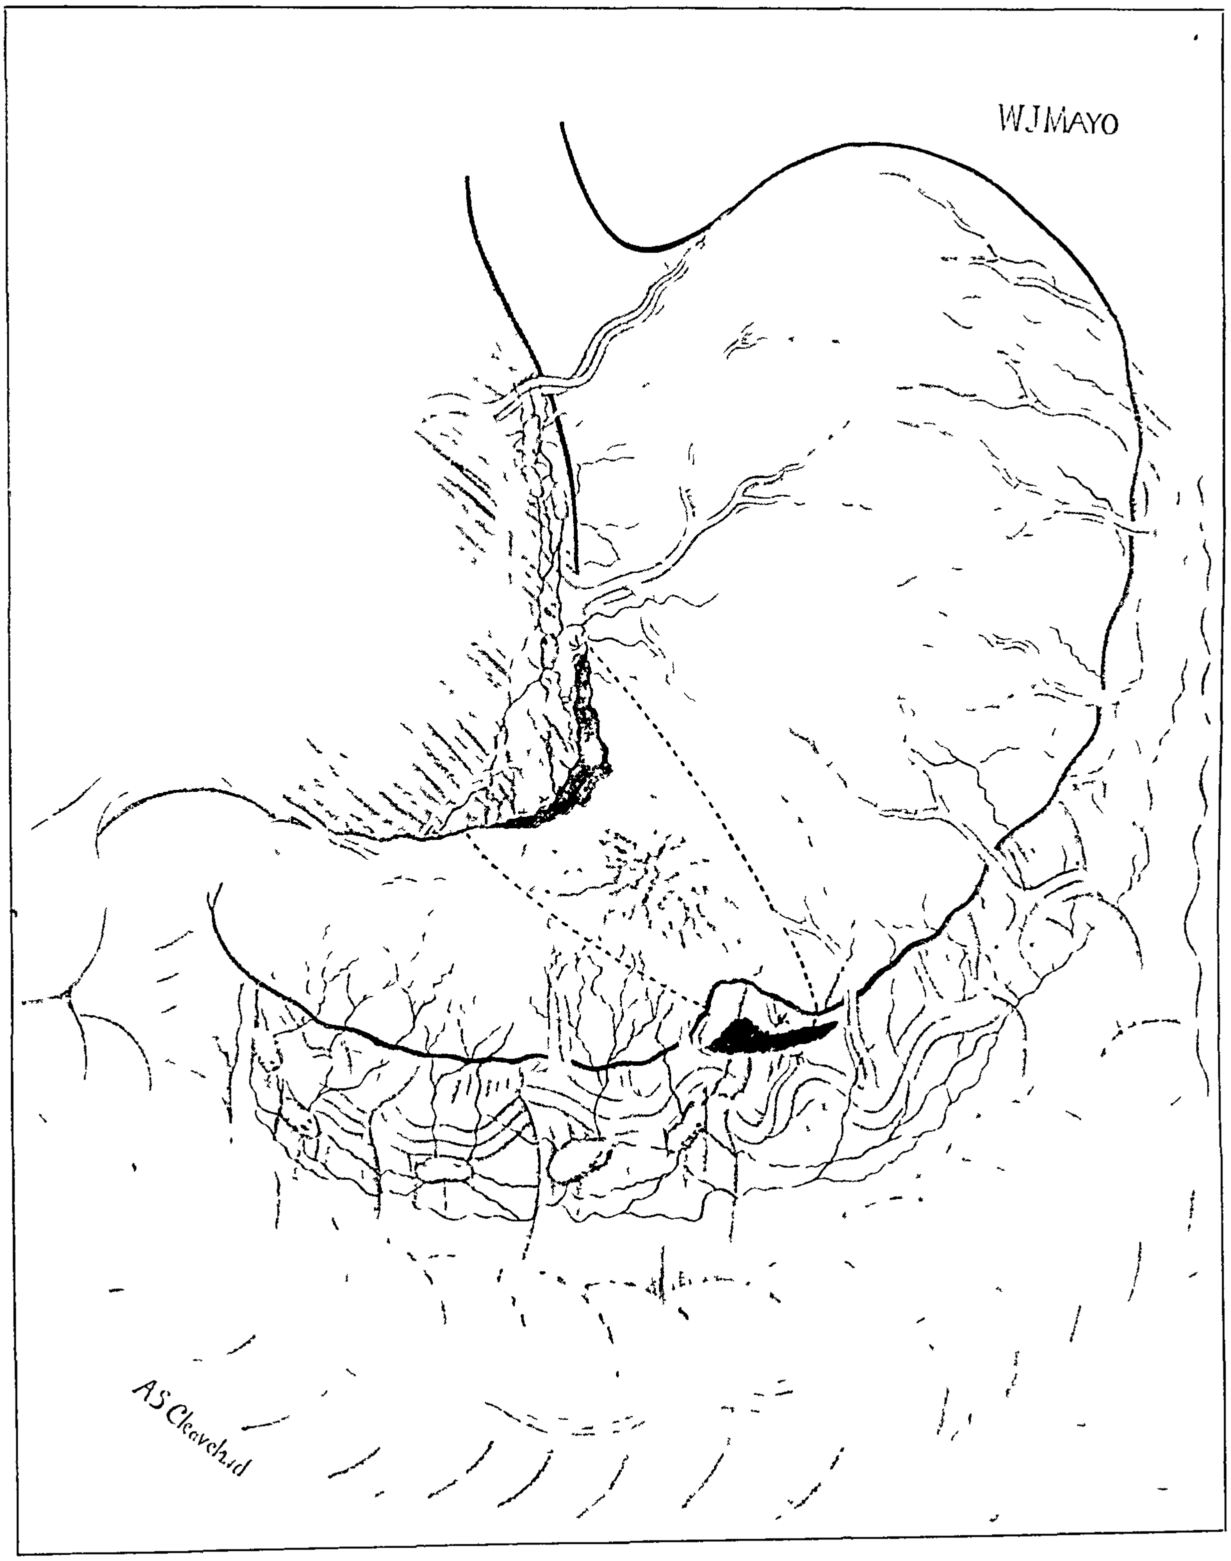

Fig 2 —Resection of hour-glass stomach with fields in gastrohepatic and gastrocolic omenta ligated Dotted lines show site of proposed resection

The predominence of the indurated over the non-indurated is even greater than would appear from these percentages. During the past year more experienced surgical examination has shown that over 85 per cent. of the stomach ulcers coming to operation have been indurated and less than 15 per cent. non-indurated. There is no question but that the frequency of non-indurated mucous lesions in the stomach and duodenum has been and still are greatly exaggerated. The very large majority involve all of the gastric coats and are capable of demonstration at the operating table. Gastric ulcers were found with nearly the same frequency in males and females. In this connection I would again call attention to the fact that ulcer of the duodenum is nearly as common as in the whole of the stomach and as more than three-fourths are in males the increased frequency of occurrence of gastric and duodenal ulcer in the male sex is accounted for. In our earlier work duodenal ulcers in the vicinity of the pylorus were classed as pyloric and added to the gastric group. In the past two years we have learned to differentiate more accurately and in the last 100 gastric and duodenal ulcers operated on, 47 were duodenal, 44 gastric and 9 had an independent ulcer of ach organ.; 62 were males and 38 females; 87 out of he 100 were of the indurated variety.

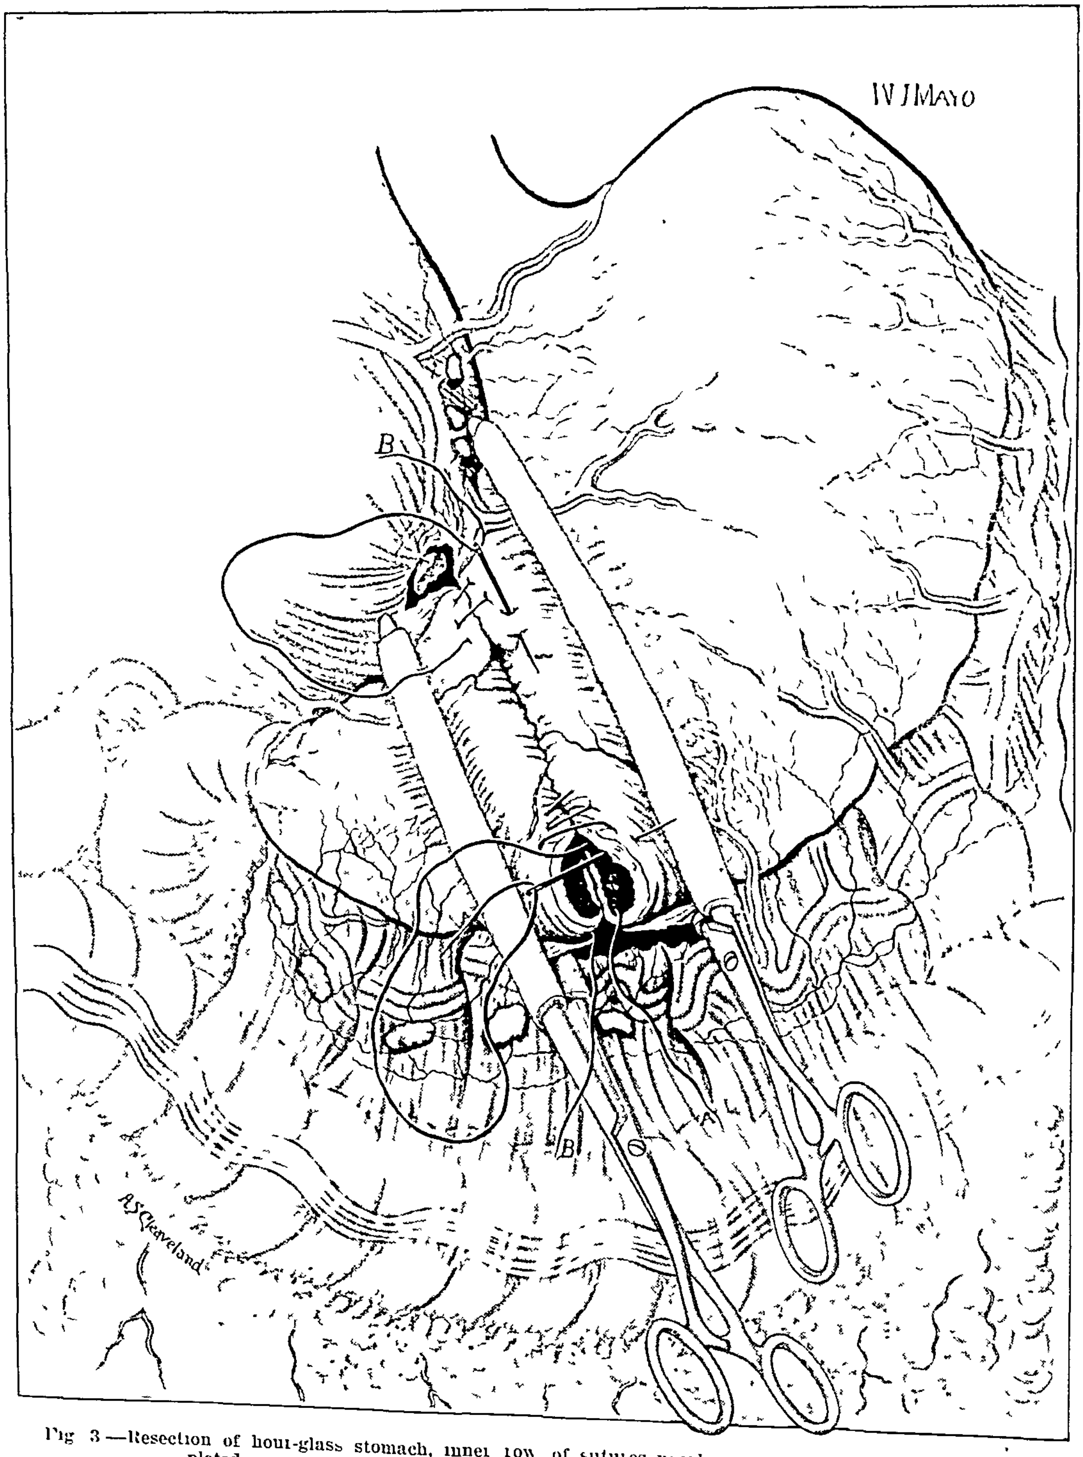

Fig. 3.—Resection of hour-glass stomach, inner row of sutures nearly completed (catgut), outer row completed on posterior surface and beginning on upper anterior surface (linen)

That a very large proportion of chronic ulcers are nedically incurable is recognized by the majority of unprejudiced investigators. It now remains to be shown whether operative treatment is justified by its results.

GASTROJEJUNOSTOMY.

Gastrojejunostomy is the operation which has justly earned the most prominence in the treatment of gastric and duodenal ulcers. It is based on the common sense principle of giving rest to the diseased part by diverting the food and gastric secretions to a new outlet which should be on the storage side of the stomach at its lowest point under the cardiac orifice. The method of choice is the one without a loop made on the posterior surface through an opening in the transverse meso-colon. The distal end of the jejunum is attached to the lowest point and to the left, the proximal part to the right three-

SOME PATHOLOGIC FEATURES OF THE PULP.*

V. A. LATHAM, M.D., D.D.S., F.R.M.S.
CHICAGO.

In offering for consideration a few ideas on the diseases of the pulp, I do not mean to infer that its pathology is different from that of any other part of the body. As a general rule, inflammation presents the same set of phenomena wherever it is situated, subject to the variations peculiar to the organ in its especial location. We must never forget that disease of an organ is seldom or never a local affair; in other words, its effects are far-reaching and other structures must always become involved. In teaching the subject, this point is one that is very difficult to impress on a student's mind, for collateral anatomy, physiology and pathology seem to be forgotten in studies in the special structure under consideration. A simple carious cavity is not the only thing by which to diagnosticate a patient's suffering.

HISTOLOGY OF THE PULP.

In former papers given in this Section[1] will be found a general résumé or compilation of both the histology and the bibliography of the pulp. It will be noted that as yet very little, if anything, is absolutely proved in its structure, and it is essential for our science that more work should be done along these lines of research. The histology and pathology of the pulp are simple, in some ways, yet at the same time very difficult. The structure of the pulp is not analogous to any other permanent tissue of the body. It has been likened to the umbilical cord or Wharton's jelly. Certainly the varieties of cells are many and their anastomosing processes are very difficult to demonstrate with the ordinary stains. If they are true connective tissue, Van Gieson's method should give the red reaction, but it does not, even with the coarser fibers for which it is best applicable.

[1] THE JOURNAL A. M. A., 1901, 1902, 1903. Especially "Résumé of the Histology of the Pulp." THE JOURNAL, July 12, 1902

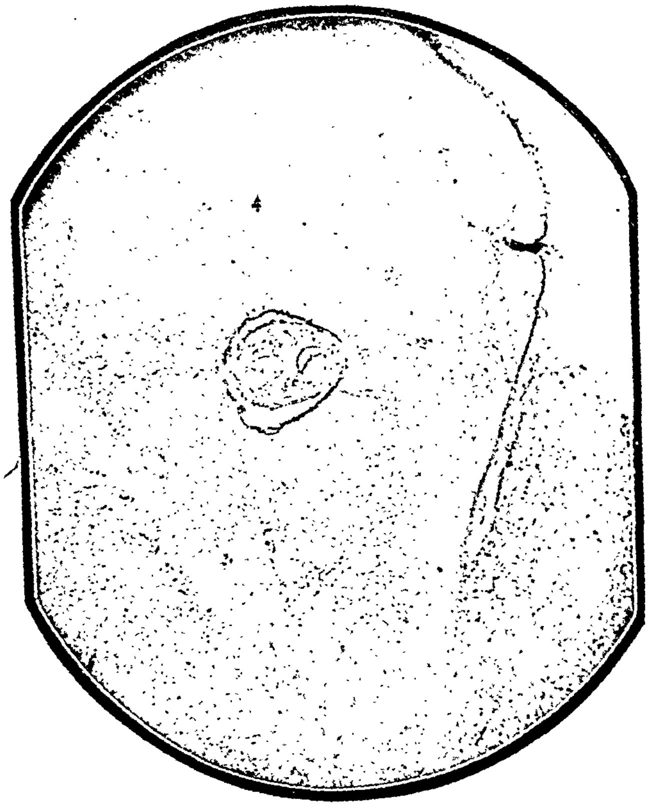

Fig. 5.—Pulp and peridental membrane, showing calcification around pulp or nerve. Note the many minute canals in same section often a cause of repeated attacks of pain after so-called pulp extraction in pyorrheal teeth.

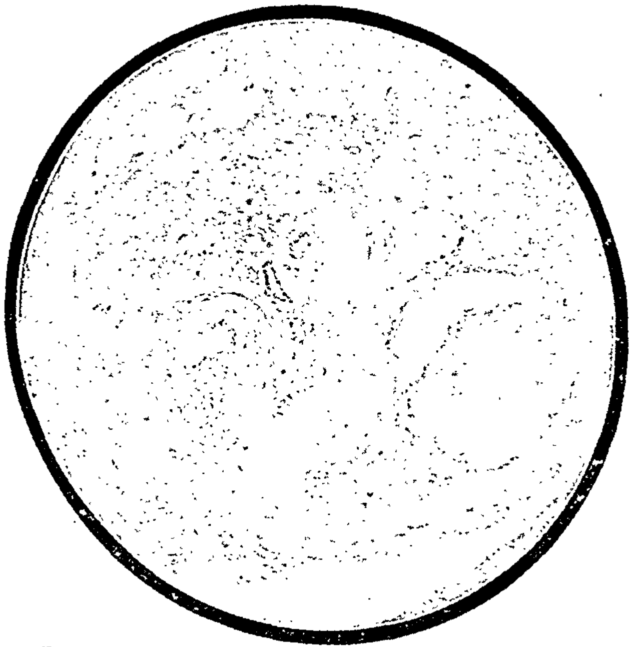

Fig. 6.—Same as Fig. 5, but magnified to show the condition of the pulp vessels. Arteriosclerosis. Venous thrombus.

In some special cases in which the pulp is of a more firm structure, almost fibroid, it is excellent. In earlier cases, as in the growing pulp, I have had better results with Ribbert's phosphomolybdic-acid-hematoxylin stain after alcoholic fixation which shows the finest fibers of connective tissue, if present. In fetal sections, the method of staining with sulph-indigotate of sodium and carmine is excellent.

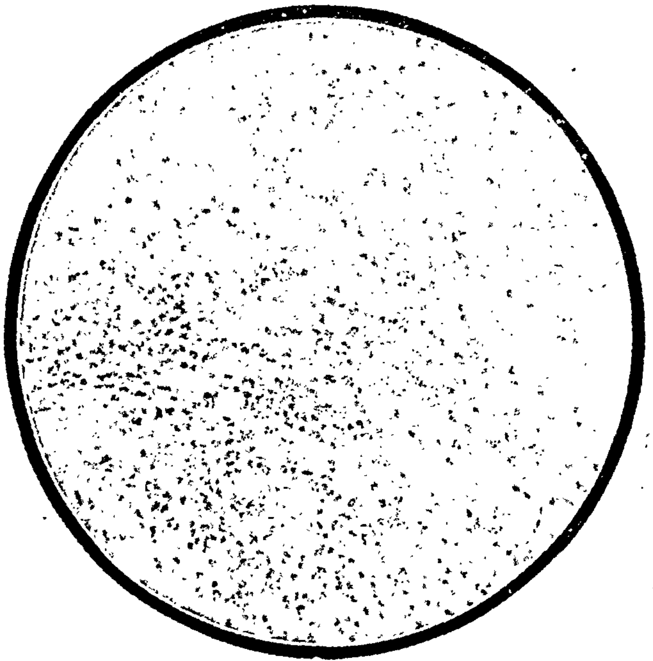

Fig. 7.—Proliferation of round cells; early fibrous tissue formation; resolution of pulpitis.

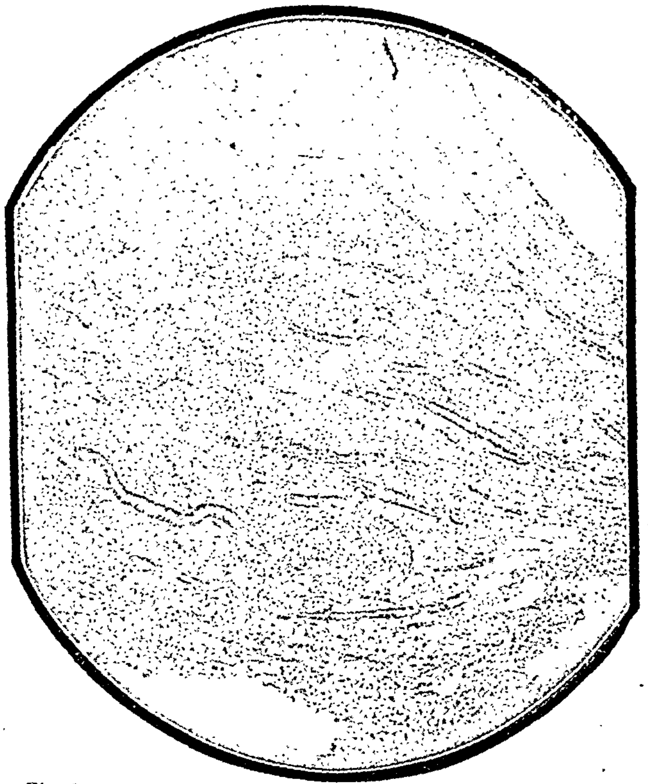

Fig. 8.—Coagulation necrosis. Areas of early suppuration. Capillary embolism.

The great difficulty that I have encountered in my work has been to determine what comprises a normal pulp. As yet the histology is incomplete, and if we compare structures in sections taken at different periods of life we find a difference in them, especially in the first molars, which have non-striped muscle fibers. So far it has not been easy to obtain freshly extracted teeth at stated periods so to make a study from an average of a number of cases of healthy persons. According to Dentz, those extracted for irregularities are abnormal in many cases. From this it will be seen that it is sometimes difficult to find a particular pulp showing some early pathologic condition, and nowhere is this more true than in the different forms of pulpitis as classified by Arkövy. Again, so little case-recording has been done in a systematic way that we are far from sure of clinical signs as yet given; certainly they do not agree with the pathologic findings.

SYMPTOMS OF PULP DISEASES.

Our text-books show that a whole series of diverse diseases of the pulp produce like symptoms, and that a whole series of diverse symptoms have for their basis a like pathologic picture. The location, the physiologic disturbances and the diseases to which the pulp is subject are more destructive and far reaching than in any other organ of the body where we have an outlet by the anastomoses present. The only method of relief in many cases lies in lessening the circulation through the vasomotor system and depletion through the excretory organs so often evidenced by the sudden stoppage of the pain when a patient is frightened on reaching a dentist's office.

CHANGES IN THE PULP.

In the case of the pulp we must consider the following facts: a. The delicate structure of the pulp is apt to undergo rapid secondary changes after an inflammatory attack whether from a constitutional or a local cause. b. Its location and poor methods of egress for exudations and dangers from compression. c. Fissures and lesions of dentine and enamel are not always able to recuperate for perfect repair. d. If a pulp has been exposed it is difficult to disinfect and hermatically to seal it under artificial methods, for chemicals act differently in different teeth and individuals. e. The small surface, the many enemies of both a bacteriologic and anatomic nature, together with almost invisible cracks in the enamel (only seen when the teeth are dry) render the occurrence of inflammation, even before decay has apparently reached the surface of the pulp, almost a sure occurrence. (f) The position and relation of the pulp, for in ill-developed teeth the pulp chamber may extend by minute processes abnormally near to the surface or even to the enamel. In such teeth many interlobular spaces are usually seen in the dentine, and the ready absorption of oral fluids and growths of yeast organisms soon cause caries. This is especially the case in the temporary incisors and the first permanent molars in early childhood and after infectious or gastrointestinal diseases followed by chemical abrasion and erosion and hyperemia of the pulp due to irritation of the nerve mechanism of the pulp. g. The question of whether lymph spaces are in the pulp or if the dentine may not act as an analogue through the tubules is still under discussion. The lymphatic supply of the jaws and teeth has not yet been determined.

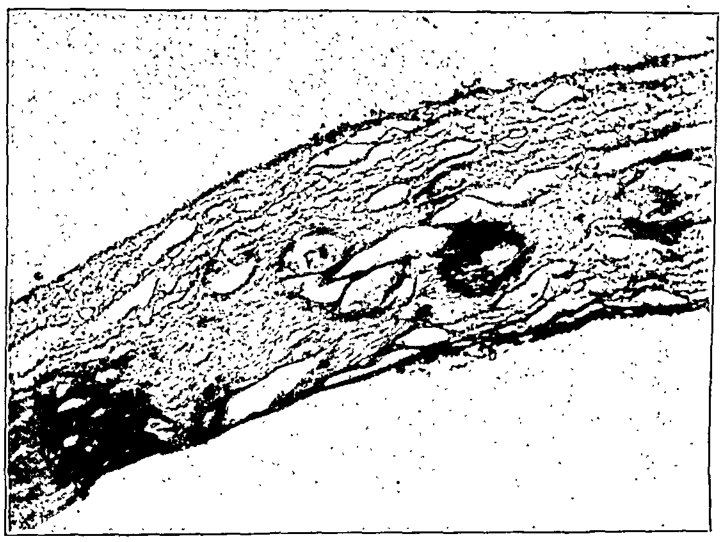

Fig. 11.—Reticular atrophy of the pulp (fibroid). Myxomatous reticulum nuclei at points of intersection and calcareous degeneration.

PULPITIS.

Let us now review the most common disease of the organ, viz., inflammation, and follow the stages.

Definition.—The definition given by the late Sir John Burdon-Sanderson is perhaps one of the best to cover so many processes and variations in different cases. "Inflammation is the succession of changes which occur in a living tissue when it is injured, provided that the injury is not of such a degree as to destroy at once its structure and vitality." To follow the pathologic changes Podwyssozki's definition is good. "Inflammation is a local reaction of the living tissues against the irritating substance. This reaction is chiefly produced by a phagocytic activity of the mesodermic cells, and it may precipitate not only changes in the vascular system, but also the chemical action of the blood plasma and tissue fluids in liquefying and dissolving the irritant agent."

Etiology.—The causes of inflammation are usually:

A. Predisposing:
  1. Deficient blood supply through walls.
    (a) bad air, (b) food,
    (c) hemorrhage, (d) anemia,
    (e) heart disease, etc.
  2. Presence of impurities or poisons in the blood, as in:
    (a) chronic alcoholism, (b) Bright's disease,
    (c) diabetes, (d) gout,
    (e) syphilis, (f) lead, phosphorus and mercury poisoning.
  3. Deprivation of healthy nerve influence by injury of a nerve center or trunk.
  4. Strumous diathesis.
  5. Old age.

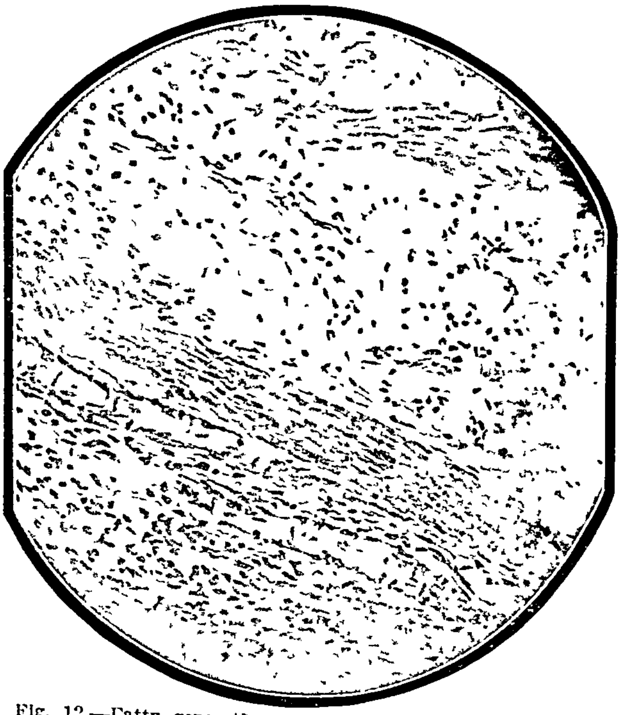

Fig. 12—Fatty generation of pulp. Sclerosis of nerve bundle Interstitial pulpitis.

B. The exciting cause is always an irritant, which may be:
  (a) *traumatic*, direct violence.
  (b) *chemicals*, acids, alkalies, caustics, vesicants.
  (c) *bacterial* fermentation, irritants, putrefactional, ptomains, leucomains.
  (d) *electric*, battery, lightning, non-insulated wires.
  (e) *thermic*, heat and cold.

Symptoms and Signs.—These may be:

1. Irritant.
2. Granulation.
3. Determination or active hyperemia.
4. Disturbance of circulation.
5. Increased motion, oscillation, retardation.
6. Stasis (partial or complete).
7. Vascular dilatation.
8. Exudation—migration, diapedesis, rhexis, etc.
9. Swellings, edema.
10. Terminations and sequelæ.
  (a) Resolution, absorption, or organization.
    1. Vascularization,
    2. Granulation.
    3. Scar tissue (cicatrix).
  (b) Chronic inflammation or sclerosis, fibroid thickening, interstitial pulpitis, cirrhosis.
    1. Hyperplasia,
    2. New formations (neoplasm).
  (c) Suppuration.
  (d) Abscess, necrosis.
  (e) Ulceration.
  (f) Gangrene.

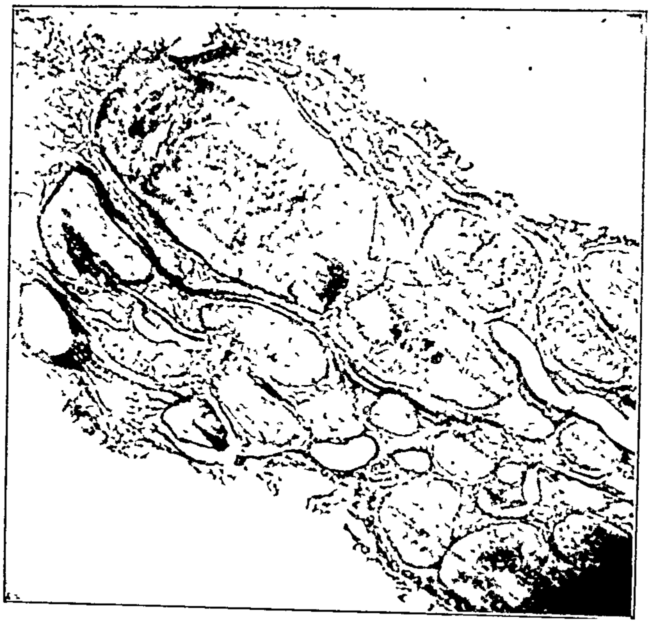

Fig. 13.—Colloid degeneration. Calcification not present of reticular or fibroid degeneration.

Chemical products of putrefaction are the chief agents in producing spreading inflammations. For fermentation or putrefaction (sepsis) there must be (a) dead animal matter, (b) some water, (c) oxygen, (d) a certain temperature, (e) presence of a ferment, which is the product of living micro-organisms. Species *Schizomycetes* (bacterial) known as saprophytes.

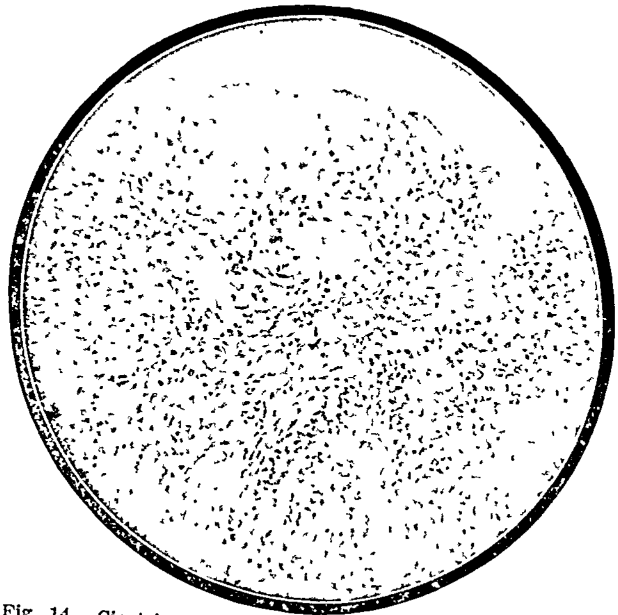

Fig. 14.—Cicatrix of pulp. Dense hyaline cell areas simulating granulation of epithelium.

The inflammation is caused not by the bacteria, but by the chemical products (sepsin and ptomains) which form in putrefactive processes, soak all the tissues and act like any irritant fluid or poisonous alkaloid.

The Bacteria of Inflammation.—Infective micro-organisms are important in cryptogenic or so-called idiopathic inflammations. Erysipelas and some forms of periostitis, pulpitis, periodontitis seem to depend on these germs and malignant pustule is proven to do so. These bacteria multiply and produce irritating products called ptomains which set up inflammation. Saprophytic bacteria live only on dead animal matter and are incapable of existing in live tissues. Some species by protoplastic activity obtain food from dead organic material, multiply and cause changes in the fluids in contact with their surface, known as fermentation. To this process are due: (a) Decomposition of serum and pus in a wound; (b) conversion of milk sugar into lactic acid in souring of milk in the stomach; (c) conversion of urea into ammonium carbonate, and so formation of ammoniacal urine in the bladder, causing cystitis, etc.

Albumin of dead organic matter in contact with these bacteria decomposes into peptones, then into ptomains and so into alkaloids.

Mode of Entrance of Bacteria.—Bacteria may effect an entrance (1) by a wound, thus producing local inflammation; (2) by lymphatics, whence they proceed to the nearest lymphatic glands, where they may be arrested; (3) by the circulation; (4) they may get into small veins and so gain the circulation at once and lodge in capillaries of the various organs; (5) from mucous membranes, as in gingivitis and diphtheria; (6) by migration from one point to another, as by extension of pulpitis gangrenosa to the submaxillary glands, as phthisis spreads from the larynx to the intestines or bronchial glands to lungs and so into the circulation. Influenza is often a cause of otitis media, oral infection and death of a pulp; (7) diseased tissue produced by one kind of bacteria may be secondarily infected by another kind. For example, croupous pneumonia is frequently infected by the tubercle bacillus and the tuberculous tissue by the pyogenic micrococcus (mixed infection). Influenza bacilli in the blood reach the pulp and cause pulpitis, ending in gangrene and cellulitis.

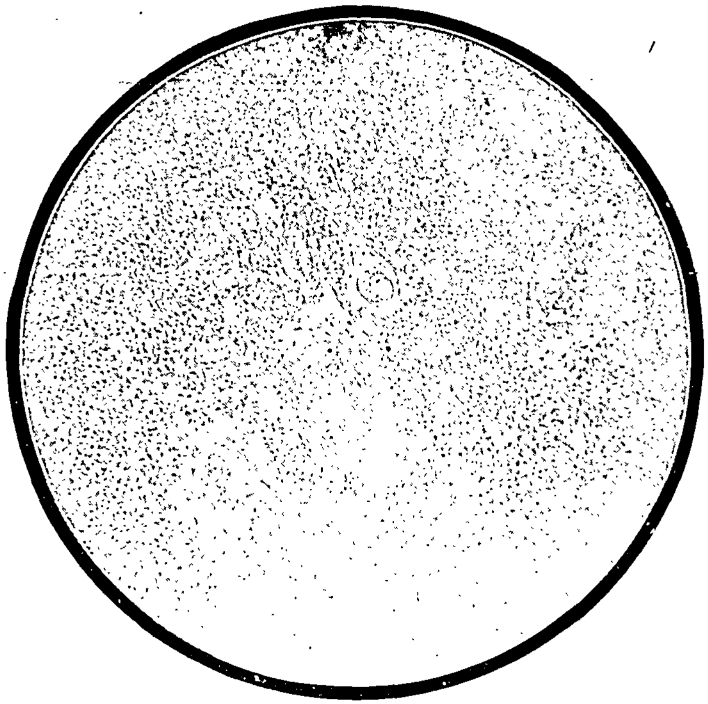

Fig. 15.—(Neoplasm). Epithelioma of pulp.

PROTECTION OF TISSUES AGAINST BACTERIA.

The tissues may be protected against bacteria (1) by exhaustion of the soil or acquired immunity, as one attack usually exempts from a second (example, variola); (2) by chemical products formed, *pari passu*, with the bacteria acting as a poison to the bacteria and preventing their development (chemotaxis). Toxins are repellant, producing a "negative chemotaxis:" (3) By tissue cells collecting around the bacteria and so killing them; (4) by phagocytosis, the cells absorbing and destroying bacteria.

Reaching the Pulp.—The irritant may reach the pulp in several ways: (1) By direct exposure as a sequel to caries, erosion, abrasion, fracture, etc. (2) Exposure of the dentinal tubules through trauma, filling, etc., and transmission by the fibrils of irritating stimuli as acids, metal fillings too close to the pulp. (3) Through the apical foramen as sympathetic depressions which may pass from the seat of injury in one part of a nerve tract and produce symptoms at a different terminal. For example, irritation by pulp stones in the third molar may cause hyperemia of the pulp in a premolar. Pulp stones in a third or second molar may cause a neuritis in the infraorbital nerve at its foramen of such a character as almost to indicate antral involvement. (4) By contact with the periodontium, especially in connection with constitutional effects as infectious diseases, mercurialism, rheumatism, malaria and especially when much arteriosclerosis is present.

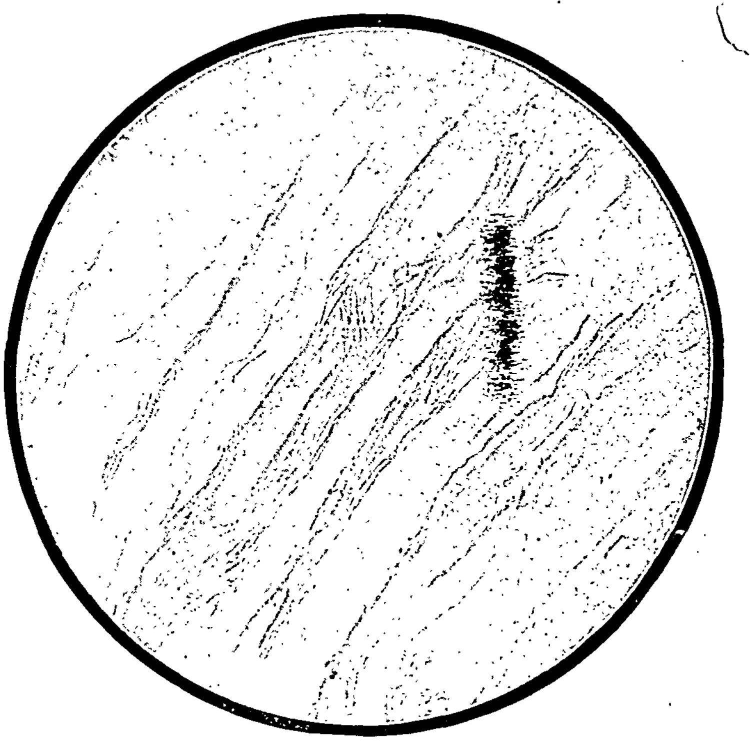

Fig. 16.—Vasomotor system, pulp, nerve degeneration slight, myelin, nodes of Ranvier.

PATHOLOGY.

When any sufficient irritation is present an active hyperemia follows, partial or complete, as in one of the cornua or radicular portions or all (Fig. 1). The cause if quickly removed may result in the pathologic symptoms abating the leucocytic migration stops, the cells are reabsorbed and no evidence is left. This is the so-called. but erroneous, "irritation of the pulp," for irritation is not the actual disease, but the cause. So far as caries is a cause of hyperemia we must recall that clinically we have a difference in the signs as presented by the type of cavities. There is, first, the cavity as seen at the cervical margin due perhaps to chemical erosion or mechanical abrasion, being sensitive to touch and conveying sensations, and, second, the further advanced type of caries, insensitive, which hardly, if ever, admits the slightest impulses to the pulp. If we study the tooth structure in these two classes we shall find different changes as regards the pulp tissue, the odontoblasts and the dentinal-enamel region, with a possible increase of interglobular spaces, and in the odontoblastic zone, an excess of calcoglobulin about the germinal odontoblasts, which latter are increased in number in the hyperemic area. Some cell proliferation is also present, (Fig. 2), showing that Nature is trying to protect herself and to protect the pulp as long as she can, thus cutting off the trophic sensations by increasing the resistance to stimuli and filling in the cavity by new if imperfectly organized tissue. Whether the odontoblasts have more to do with the vasomotor system than with dentinification is as yet an open question, but clinically it would seem as if they have, or at least that they assist more materially.

Pulpitis is the common termination of hyperemia, and histologically the pulp shows very different degrees of interest Cases should be taken from teeth, first, in which caries has not penetrated into the cavity and, second, in which there is exposure. We find in some specimens a well-marked cell infiltration, dilated vessels on account of the stasis of the circulation and evidences of edema which may be seen by the poor staining of the tissues which look water-logged (Fig. 3). This distension shows the clinical evidence of pain by pressure of the odontoblasts against the dentine and the constriction by the alveolar dental membrane through inflammation of the vasomotor nerves scattered through the pulp and constriction of the vessel walls (Fig. 4). The endothelial cells are easily lost by the dissolution of the cement substance, and with the cell changes we obtain clotting, thrombosis and embolism (Figs. 5 and 6). This condition I have often seen in teeth extracted for interstitial gingivitis or pyorrhea.

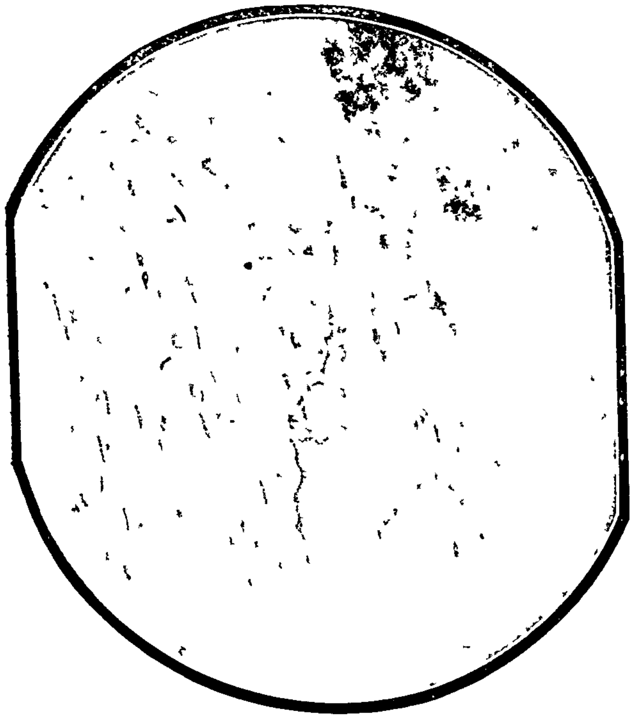

Fig 17—Nerve degeneration, thickened fibers Nuclei well marked

A CASE OF PULPITIS.

Let us take for examination a tooth which has been the subject of periodontitis followed by a pulpitis and then quieted down. Note, first, the thickened membrane and that at certain places there are absorption areas or excavations with large giant cells;[2] in another place in this root are older absorption spots and a layer of new tissue filling them up and increasing the size of the tooth (hypercementosis). The pulp cavity shows that there has been a change in the layer of odontoblasts which form the attachment and act as a source of nourishment from the pulp to the dentine. It is from this layer (the connecting link between the hard calcified dentine and pulp matter) that the so-called secondary dentine is formed, but under certain circumstances the characters of the cells forming this layer change both in size and shape (Fig. 5). If we have a hyperemic condition or slight pulpitis, a great amount of blood is brought to the pulp blood vessels. These cells lose their shape, swell up, the nuclei become active and new cells are rapidly formed by mitosis (Fig. 7). As these new cells proliferate, a thickened membrane-like layer is seen pressing on the dentine and so causing an absorption of the latter in order to gain more room for growth (Fig. 6). Just so long as we have an abnormal blood supply to the pulp, a long or short time of pressure on the hard walls, so long do we have few or many absorption areas which may be superficial or deep. If the tissue is imperfectly calcified around the pulp canal, the giant cells will more easily penetrate and pass out in all directions continuously or intermittingly, depending on what changes are going on externally on the tooth or in its cemental layer. If extracted about this period nothing is found of the pulp or only a thickened membrane on the pulp canal walls These changes are produced by the odontoblast layer of the canal, and if not extracted we find the pulp congested, odontoblasts altered or destroyed and no connection with the tubuli (Fig. 8). In the dentine, giant cells are becoming formative agents, building a new tissue resembling a poor type of dentine, cement or bone-like material with its lacunæ and canaliculi in the en-

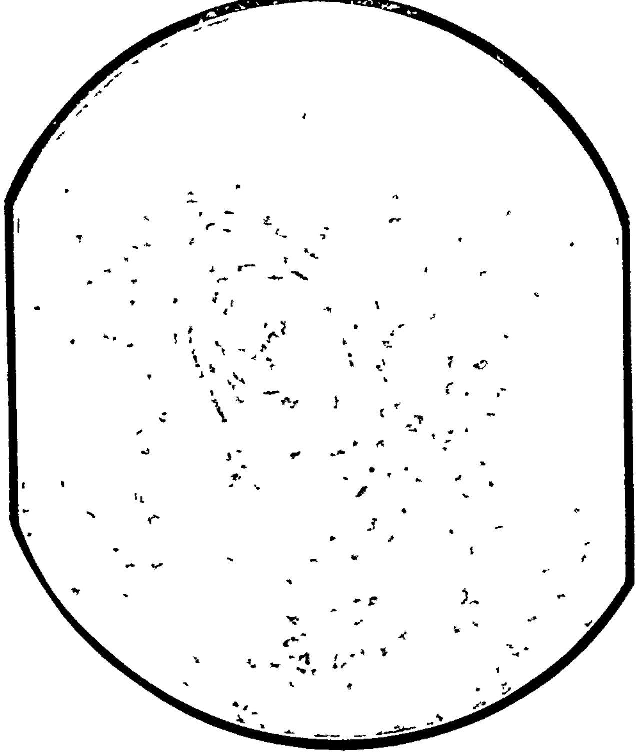

Fig 18—Arteritis obliterans of pulp Parenchymatous degeneration Thickened nerve bundles in pyorrheal tooth

larged pulp, developed from a membrane very similar to that of the periodontium. These same changes may be seen in the incisors of horses, cows and dogs. The vascular system returns to the normal. Clinically the tooth is tender to percussion almost as in periodontitis; this gradually subsides until another inflammatory attack recurs, then interstitial periodontitis with resorption and loosening of the tooth. If this continues we may have to extract the tooth, for through this calcific degeneration we may have many reflex conditions as well as gingivitis, even to suppuration (Figs. 10 and 11).

[2] Coyne and Cavallé: Anat. Anzeig., 1905, vol. xxvii, p 205

In the more chronic cases we really see the influence of the defective ways of egress. Everything in the way of pathologic histology which belongs to the retrogressive disturbances of nutrition may occur, as interstitial pulpitis, suppuration, necrosis, gangrene and the various degenerations (Figs. 8 to 13). When a tissue is dead we never hear of its recovering. But just previous to death we may have a line of demarcation in the healthy tissue in the body, as in gangrene of the extremities, but this is a rare sequel in the pulp on account of the peculiar anatomy in the radicular part of the tooth, and because its apical entrance provides no way of egress or ingress. Cases do occur in which cicatrization has been seen both in so-called healed caries and in pulps in which punctures have been made intentionally for hyperemia, or accidentally (Figs. 7 and 14). I feel that as soon as we can secure aseptic or even antiseptic cavities, and tissues, especially in the dentinal tubules, and freedom from enamel fissures we may expect a greater number of pulp recoveries if the patient be in good general health.

As a termination by hyperplasia from a chronic pulpitis we need only note the so-called polypus of the pulp which has been ably studied by von Römer.[3] We all know the comparatively non-sensitive mass consisting of rather thick granular tissue in three layers, the outer having white blood or pus cells beginning to break down, the second the capillary vessel layer and endothelial cells almost like granulation tissue, and the third connective tissue with enlarged vessels and many round cells. He especially noted an entire absence of nerves or only a few nerve fibers. In the pulp cavity itself and in the canals numerous nerve bundles were seen degenerating. Such can be best seen in pulps which have been laid bare by fracture in attempts at extraction and in which the superficial pulp is cicatrizing. The differences between pulp hypertrophy and *pulpitis chronica hypertrophica granulomatosa* as quoted by Rothmund and Arkövy[4] may not exist, says Dr. von Römer. Certainly a growth which follows the type papilloma is usually different to the interstitial pulpitis or fibroid form by having a richer supply of blood vessels more dilated like an angioma and less fibrous tissue.

With regard to the other termination as a possible result of pulpitis, neoplasm or true tumor growth (Fig 15). I refer to my paper in which the literature and work has been discussed.[5] In order of frequency in a series of cases taken from the records of the Dental Hospital of Budapesth (Anton Kozma)[6] it was determined that acute periostitis is rarer than any other inflammatory disease, next maxillary affections. and then acute pulpitis. then follows chronic periostitis and. as borne out by my own histologic studies. chronic inflammation of the pulp, or. as I prefer to designate it, interstitial pulpitis. A peculiar circumstance is that the frequency *of all inflammatory diseases* in the upper jaw increases to the first molar and from thence decreases. The same order also occurs in the lower teeth. It may be said that in the first molar there is hardly any disease that one has not the opportunity of investigating.

If the teeth are considered individually, the inflammatory conditions in the upper premolars, incisors and cuspids occur more frequently than in the corresponding lower ones. But this is not so with the molars, the inferior of which suffer more than the superior, and this corresponds with the statements of Magitot and Kay, J. Tomes, S. Cartwright and Hitchcock.

In studying pulpitis there are specimens in which the most careful work by staining for bacteria does not show them to be present in the tissue of the pulp, more especially in the chronic or interstitial forms. Sections may show the dentinal tubes carrying some, and in others the pulp and odontoblast layers show them and also degenerative changes in the cells themselves. An interesting study could be made by examining sections of the pulp. especially stained to show the probable distribution of the micro-organisms, if they penetrate the basal layer of Weil and the probable routes of invasion into the pulp.

NERVE DEGENERATION.

Nerve degeneration so far has been little worked out in the pulp, but that it is present is evident. The degeneration of a severed nerve is well known in surgical practice, but it is not often remembered that simple contusion may have the same effect as severing the continuity of a nerve trunk. A contusion may abolish the function of a nerve for some hours, but if the function is not restored within a reasonably short time degeneration of the nerve may follow just as if it had been severely injured (Fig. 17). The peculiarity of nerve contusion is that it leads to neuritis and so may give what is really a pressure paralysis owing to the histologic structure.

As we know, a nerve trunk is made up of a number of bundles of nerves, each surrounded by a connective tissue sheath. This strong fibrous sheath plays an important rôle in the pathologic study of neuritis. The nerve has its own lymphatic, vascular supply and a special nerve supply to give it local sensibility. A contusion may, and in some cases does, set up a secondary neuritis. congestion, cloudy swelling, edema and distension of the nerve sheath which is an unyielding connective tissue. and if the inflammation is severe the compression of the nerve fibers gives us pressure paralysis and very soon the nerve degenerates. The symptoms may be obscured at the time of the pain and swelling. Micro-organisms may follow and infect the nerve fasciculi, as they usually arrange themselves along the blood vessel walls.

Whether the odontoblasts have a phagocytic function as suggested by Arkövy[7] is not proved yet. Figures 16 and 17, if compared, show degenerative changes in the ground work and very slight swelling at the nodes of Ranvier, some collection of the myelin substance, while Figure 12 shows a sclerosis, fatty degeneration and (Fig. 17) thickened fibers.[8]

[8] In addition to writers cited in the text, the following were consulted in the preparation of this article: Andrews, "Calcoglobulin." Dental Digest, December, 1904; Dental Cosmos, November, 1904. Talbott, "Vasomotor System of the Pulp," THE JOURNAL A. M. A., Dec. 9, 1903; "Constitutional Causes of Tooth Decay," Dental Digest, December, 1903; "Pulp Degeneration," THE JOURNAL A. M. A., Aug. 6, 1904, p. 385; "Endarteritis Obliterans and Arteriosclerosis in the Alveolar Process," Dental Digest, 1904; Scheff's "Handbuch," No. 2, p. 297; "Ein Beitrag zur Statistik der Zahn Caries," Inaug. Dissert., Kiel, 1886; Rothman, "Patho-Histologie der Zahnpulpa und Wurzelhaut," 1889; Wedl, "Atlas zur Pathologie der Zahne," p. 68, 1893.

The loss of control of the vascular system of the pulp and obstruction in the vessels followed by inflammation are probably factors in interstitial gingivitis which may be a cause of the gingivæ losing their normal function and so aiding in the progress of the disease (Fig. 17). The interference with the vascularity of the bone, the arteritis obliterans in the pulp and peridental membrane (Fig. 18) producing venous hyperemia of the gums. (acute or interstitial), changes in the mucous glandular structure and functions, and finally atrophy and osteomalacia.

DISCUSSION.

Dr. M. I. Schamberg, Philadelphia, said that for a long time dentists were prone to regard the pulp as merely a bundle of nerves. By the work of Dr. Latham we are made to believe forcibly that there are many pathologic conditions which are prevalent in other parts of the body and at the same time found to exist in the pulp. When he saw Dr. Latham's slides about a year ago he was much impressed with the fact that it would probably be best to remove all pulps which were even closely approximated by decay, if not entirely exposed. He was glad to hear Dr. Latham give evidence of the fact that some of these conditions might be alleviated or improved by the proper treatment, because the conservation of that organ prevents numerous complications which arise when we attempt to fill canals which are very minute and which are extremely important.

Dr. E. S. Talbot, Chicago, said that Dr. Latham held the opinion that it was difficult to say when a pulp is in a healthy condition, or to demonstrate a healthy pulp. It is a singular thing that in the evolution of a pulp from the lower vertebrates up to man, a general degeneration of the pulp occurs, and as we ascend from the lower vertebrates we find that the pulp gradually grows smaller and smaller, until in man the apical end of the root is almost entirely closed, so that we have a pulp mass consisting of blood vessels, nerves and connective tissue inside of the tooth. He believes that the pulp is at its highest physical development when it commences to form dentine. The mere fact of its growing smaller and smaller at that time would lead one to believe that degeneration was going on. Why we ever have a healthy pulp he did not understand. Dr. Latham had demonstrated almost every pathologic condition that is possible to be found in the human body. Ten years ago Ramón y Cajal of Madrid, Spain, found a stain by which he was able to show a nerve-end degeneration, and for the last eight or ten years the members of this Section have been using it along the line of research work. He, himself, had been studying the pulp for the last ten years with Dr. Latham, and some beautiful work had been done showing nerve-end degeneration in the pulp tissue. Arteriosclerosis, as well as fatty degeneration, had been noticed. The question naturally arises then, where so many primary diseases are found in the pulp, is it not better under most conditions to extract or to remove the pulp and to fill the root of the tooth, rather than to try to cap and to preserve it.

Dr. V. A. Latham added that one point was not made plain in regard to pain in teeth after pulp extraction. There are two photographs (Figures 5 and 6) which show the center pulp chamber being occluded by arteriosclerosis and beside that the amount of dentin forming around has practically obliterated the chamber. Six or eight exceedingly minute but distinct pulp canals are seen. This is a case in which one may extract the pulp and think the work is done, but on careful manipulation a condition will still be found to remain, and the patient will return day after day, saying: "Doctor, that tooth still hurts." Dr. Latham had another case in which the nerve, instead of going through the central chamber, actually came through the cemental surface into the peridental membrane. On passing a probe down at the side, pain was felt which nearly made the patient jump out of the chair. After extraction the nerve was found coming out at the lingual side of the tooth, to the gingival margin. It was not a case of hypersensitive cement or dentine as diagnosticated by several. The erratic position of the pulp and its terminal fibers is a matter of considerable importance to stomatologists and physicians in the matter of reflex disturbance.

CEREBRAL DECOMPRESSION.

PALLIATIVE OPERATIONS IN THE TREATMENT OF TUMORS OF THE BRAIN.

WILLIAM G. SPILLER, M.D.
AND
CHARLES H. FRAZIER, M.D.
PHILADELPHIA.

(Concluded from page 853.)

Case 11.—Tumor of cerebellum.

History.—F., aged 16, was referred to Dr. Spiller, July 16, 1904, by Dr. J. S. Baer and Dr. R. G. Curtin. The father of the patient possibly had had syphilis. The menses ceased about two years ago; having begun when she was 14, they had, therefore, been present only a short time. For about one year she had had a severe sensation of pressure at the back of the head, as though some one were pressing her brain out, but this sensation is not felt now. She has had headache, not localized to any one part of the head, and has had "neuralgia" in the left side of the forehead about a year. Before December, 1903, the headache was severe. About a year ago she began to have nausea and vomiting, at first about every six weeks, but these symptoms gradually became more frequent until they occurred every two or three days. The vomiting had no relation to eating. About a year ago she began to be dizzy, but has not been dizzy since February, 1904. Dr. Risley has recently discovered optic atrophy, secondary to choked discs. She has never been unconscious. She has had difficulty in lying on her right side, but this sign seems to have disappeared. Lying on the right side caused her head "to kind of draw." She has never had convulsions. Sight has been fail-

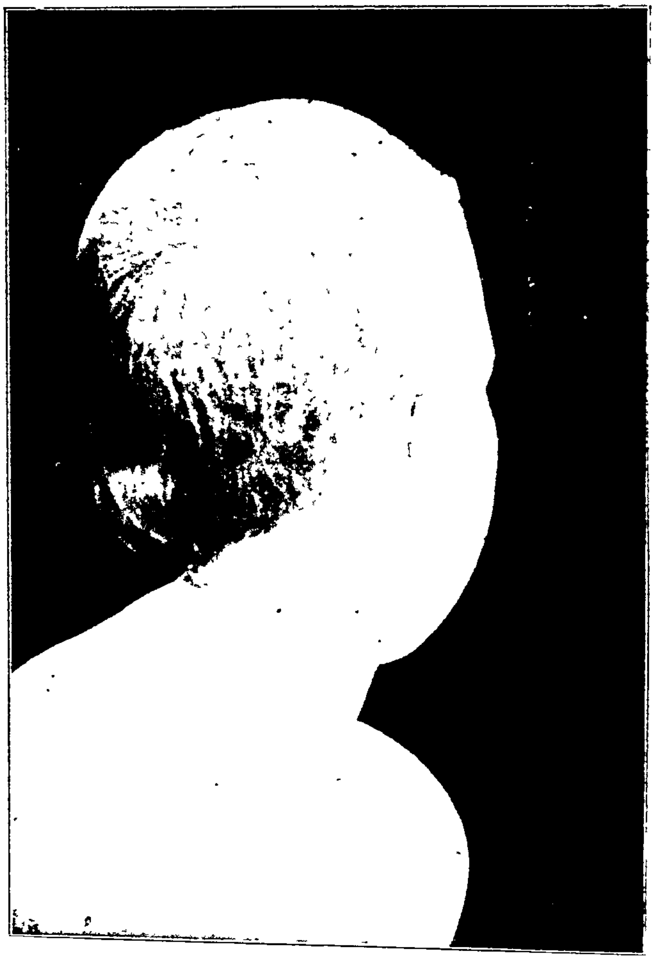

Fig. 4.—Showing a hernia cerebelli after a unilateral suboccipital craniectomy. The patient prior to the operation had been bedridden for over a year, is now able to be up and about and has been relieved almost entirely of her pressure symptoms (Case 11).

ing about two years. Difficulty in walking was noticed about November, 1903; she staggered, and the staggering seemed to be more to the left.

Present condition, July 16, 1904: There is no involvement of either seventh nerve masseter contracts well on each side, tongue protrudes straight, not atrophied and shows no fibrillary tremors. Movements of eyeballs are free in all directions, but distinct nystagmus is observed in turning the eyes far to the left or right, and probably is more intense in turning the eyes to the right. The right pupil may be a trifle larger than the left. The reaction of the pupil to light is preserved, also in convergence. Accommodation can not be tested because of poor sight. She can count fingers with either eye, but the sight is more impaired in the left eye. She hears a low-ticking watch one or two feet from either ear, and has not noticed any deafness. She has had buzzing in both ears, especially in the left, but Dr. Baer states that she has had accumulations of wax in the ears. The face is somewhat puffy and expressionless. The exit points of both fifth nerves are sensitive, but the left supraorbital foramen is more sensitive than the right. She now holds her head straight, but says she formerly inclined her head to the left. Sensations of touch and pain are normal in each side of the face.

Upper Limbs: All the movements are free; the grasp of each hand is normal. The biceps and triceps reflexes are not distinct on either side. Sensations of touch and pain are normal in each upper limb. The finger-to-nose test with eyes closed does not show distinct ataxia.

Lower Limbs: Voluntary power is normal. The patellar reflex may be a little prompter than normal on each side. She staggers a little when standing erect with eyes closed, and the gait is uncertain, with a tendency to stagger more to the left. The gait is cerebellar in type, but the staggering is not intense. The Achilles jerk is not distinct on either side, nor is the Babinski reflex. Sensations of touch and pain are normal in the lower limbs.

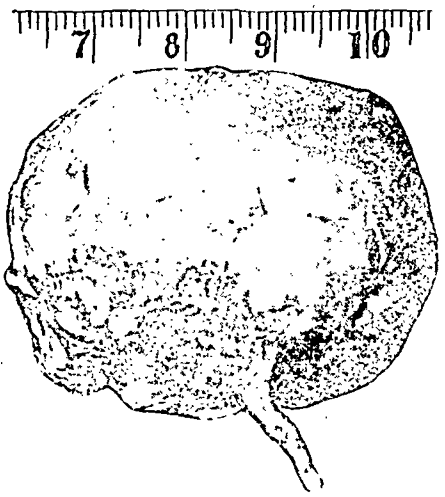

Fig. 5.—Fibroma removed at operation (Case 12). The patient lived five days after this operation.

Dr. W. H. Powell first examined the eyes in November, 1903. Vision of the right eye, 20/50; of the left eye, 20/50. Pupils react to light and accommodation. Peripheral vision normal, media clear, but fundus suggests a low grade of neuritis. In July, 1904, vision of the right eye was 20/100, of left eye 4/200, and she had optic atrophy and markedly contracted fields.

Chiefly because of the history of probable syphilis in the father I employed mercury and iodid, and by Aug. 16, 1904, her gait had become less ataxic. By May 5, 1905, headache had disappeared, but about once a month she still had a drawing sensation, as though the brain were being pulled out. Ataxia was slight. The patellar reflexes were about normal.

Feb. 22, 1906, Dr. de Schweinitz found typical postpapillitic atrophy.

Operation.—March 9, 1906, suboccipital craniectomy was performed by Dr. Frazier under ether anesthesia. The operation consisted in removing that portion of the occipital bone overlying the left cerebellar hemisphere.

Subsequent History.—March 28, 1906: Since the operation was performed the condition of the patient has improved, but only to a moderate degree. The pain referred to the arms has been very much less severe and at times she has had none at all. Her headaches also have been less severe and less frequent. Although confined to bed for the past year, she is now able to get up in a wheel chair. Although the dura was neither incised nor removed at the operation, there is quite marked bulging over the left cerebellar hemisphere, showing that the dura has yielded to the pressure from within and that it is possible for a hernia to develop without opening the dura.

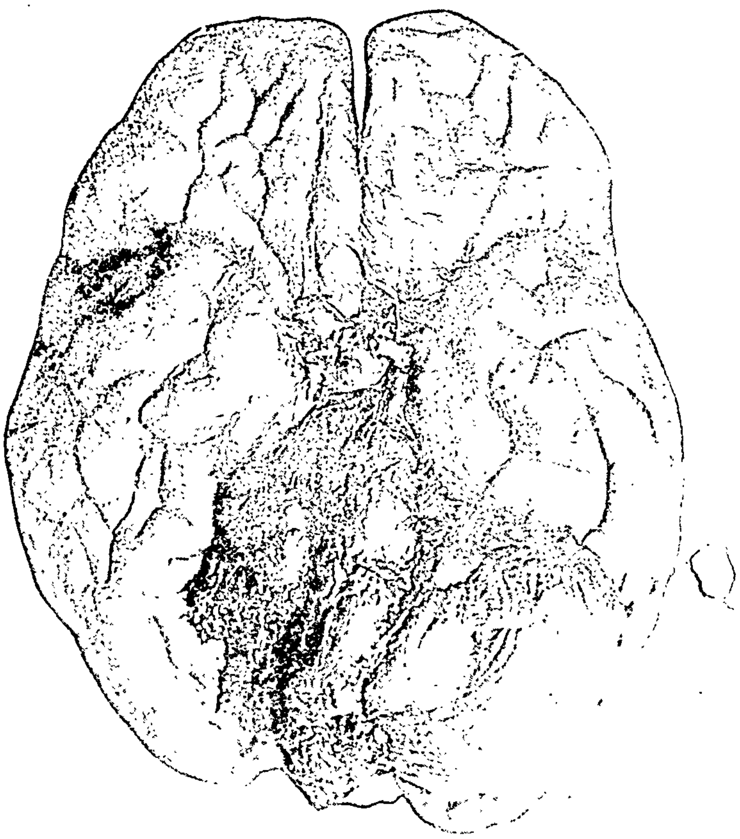

Fig. 6.—Brain from Case 12, showing portion of tumor in right cerebello-pontile angle not removed at the operation.

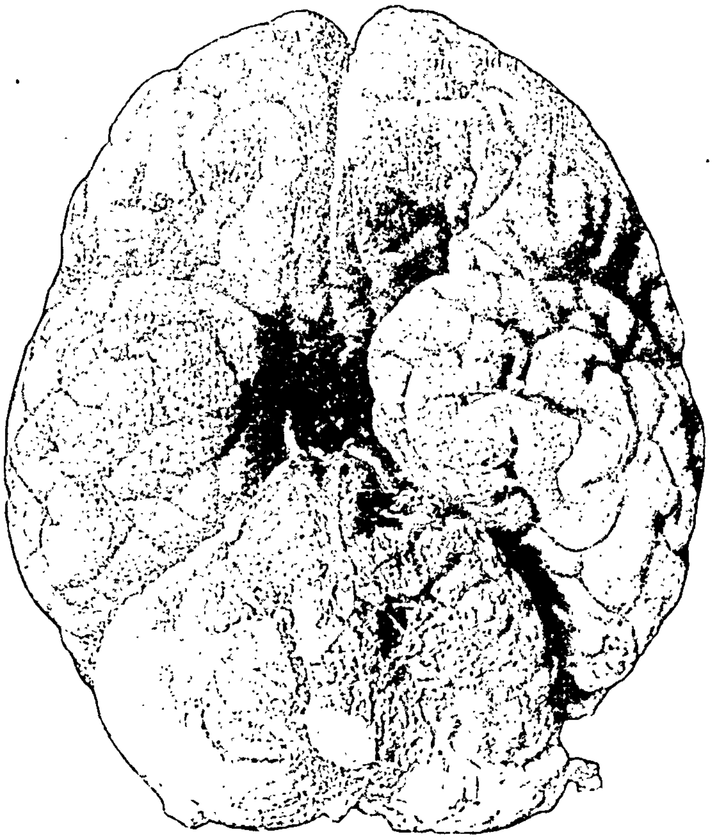

Fig. 7.—Tumor, probably a fibroma, of the left cerebello-pontile angle (Case 14).

Second Operation.—April 4, 1906: After consultation with Dr. Spiller it was decided that, owing to the fact that the headache and pain in the arms had not been entirely relieved, it would be advisable and afford greater relief to the increased tension to split the dura. Following an injection of 1-6 gr. of morphin, and under ether anesthesia, the left cerebellar hemisphere was exposed by a muscle-splitting operation. A vertical incision was made through the middle of the original flap, the edges of the wound retracted and a crucial incision made in the dura about 1½ inches in either direction. The cerebellar tissue bulged considerably through the opening, but the exposed tissue was normal in appearance. The musculo-aponeurotic layers of the wound were closed with catgut sutures and the scalp with interrupted silkworm gut sutures.

April 16, 1906: The following notes were made by Dr. Spiller: The paralysis in the lower distribution of the right facial nerve supply is distinct, although the upper distribution of the nerve does not seem to be affected. She has light weakness of the right upper and lower limbs. The patellar reflex is prompt on each side, but more prompt on the right, and there is slight tendency to ankle clonus on the right side. The Babinski sign is present on the right side, but uncertain on the left side. There is no disturbance of sensation for touch or pain in any part of the body.

May 23: For the first few weeks after the second operation the patient had occasional headaches and pain in the upper extremities. For the past two weeks, however, she has been almost entirely free from both these symptoms. She has gained in strength and is able to be up a considerable portion of the day. A hernia cerebelli has increased somewhat since the second operation (Fig. 4). She has recovered sufficiently from the effects of the operation and is sufficiently relieved to warrant her being discharged from the hospital. Her gait is still ataxic. She menstruated in May, 1906, the first time within a period of four years.

Case 12.—Cerebellopontile tumor. Decompressive operation, followed by disappearance of headache, vomiting, and by subsidence of choked disc.

History.—E. D., aged 24, was referred to Dr. Frazier by Dr. Sherman Voorhees, of Elmira, N. Y. She was seen in consultation also by Dr. Spiller. About two years ago the patient noticed that her limbs were weak, that she would stagger in walking, although she did not feel dizzy. About one year ago she began to notice that her vision was failing. At this time she would have attacks, when for a few minutes everything before her would seem black; following the attacks she could see perfectly well again. At the same time she began to have attacks of nausea and vomiting, and noticed that she was becoming slightly deaf in her right ear. For the past three months she has had considerable headache, sometimes dull, at others sharp and shooting in character. At the time of her admission, Feb. 16, 1905, she is practically blind and unable to walk.

Examination.—February 17: It was noticed that in showing her teeth the right corner of the mouth is not drawn up nearly so well as the left, and in drawing up each corner separately the movements on the right side are distinctly less than the left. On closing her eyelids forcibly the resistance to passive movements is less on the left side than on the right side; the masseter muscle seems to contract equally well on one side as on the other. The ocular movements are normal and there is no distinct nystagmus. There is no disturbance of pain and tactile sensation in the face, although she complains of a "queer" feeling on the right side of the face and right side of the mouth and of the face feeling numb, as though it were asleep. Further examination gives the impression that both the left temporal and masseter muscles contract a little more than the right, although it was subsequently found that on both sides the muscles respond equally well to Faradic current. The tongue is protruded straight and there are no fibrillary tremors. The right eyelid seems to be slightly more prominent than the left.

In the upper extremities the grasp of each hand is normal. Biceps reflex is normal on each side; the triceps reflex and wrist reflexes are not distinct on either side. Sensations for touch and pain are normal on both sides. There is slight ataxia on each side, a little more on the right.

In the lower extremities the patellar reflex is a little prompter than normal on both sides. There is no ankle clonus. The Babinski sign is uncertain in each side, as she resents any attempt to irritate the sole of the foot. The Achilles jerk is absent on both sides; there is no hemiasynergy and no weakness of any of the limbs; gait is slightly ataxic, specially noticeable when she turns; in walking the patient staggers more to the left than to the right. She staggers when her feet are together almost as much when her eyes are open as when they are closed.

Examination of Ear: Dr. Randall finds little hearing in the right ear by air or bone, except for the Galton whistle. Tests are slightly contradictory, but indicate middle ear trouble on the right side, complicating semi-complete right acoustic paresis. Hearing on the left side is not impaired.

Ophthalmic Examination by Dr. Shumway: Pupils are dilated; right pupil responds when light is thrown in from the temporal side, in which position it is recognized. The left pupil does not respond to light and the eye is blind. There is choked disc on both sides; elevation on the right side is about 6 D. and on the left 7 D. The nerves are beginning to atrophy. The eye movements are carried out in a jerky manner, the muscles acting feebly, and the eyeballs return to primary position immediately. There is no paralysis of the ocular muscles.

Operation.—February 23: Under ether anesthesia Dr. Frazier performed a suboccipital craniectomy, removing the bone overlying the right cerebellar hemisphere. Owing to the fact that bleeding was so profuse, it was decided to discontinue the operation at this stage until the patient had fully recovered from its effects.

A radical operation was performed two months later and was followed by death within five days (Figs. 5 and 6). After the decompressive operation the choked disc subsided from 7 D. to 3 D., although, unfortunately, the optic atrophy was so advanced that it precluded the possibility of restoring the vision. The hearing improved somewhat after the operation and the nausea and vomiting ceased. Headaches disappeared almost entirely and the patient was able to get up and walk about the ward with but little assistance.

Case 13.—Inoperable tumor of brain. Decompressive operation, followed by little or no amelioration of the symptoms, although prolonging the patient's life.

Patient.—R. C., aged 30, was referred to Dr. Charles H. Frazier by Drs. Thomas O. Nock and Wharton Sinkler, March 15, 1906, the latter having seen the case in consultation.

History.—There was a history of the patient having had an attack of vertigo while walking about three months ago, and had she not been caught by her husband she would have fallen to the ground. At the same time she had some numbness in the left upper and lower limbs. Since that time she has had two attacks of numbness of the limbs, but no vertigo. She has had more or less persistent headache for the past year, occurring about three or four times a week, usually in the mornings. There have been no convulsions. Three weeks ago the symptoms became much more severe, headache more intense and numbness in the left extremities more marked. At this time it was noticed that the muscles of the left side of the face were gradually becoming weak, the muscles becoming paralyzed within a period of from four to five days. Up to this time there was no weakness in the extremities, but about a week after the involvement of the facial muscles was noticed the grasp of the left hand became weak, and about the same time weakness was noticed in the left lower limb. The upper extremity sometimes is flaccid, at other times spastic, but the lower extremity has never been spastic. The pulse has varied between 44 and 60. The respirations have been alternately shallow and moderately full, the respiratory rate ranging from 16 to 30 a minute. For the past four or five days her temperature has been subnormal. About eight days ago for the first time the patient became stuporous for variable periods of time. These periods of stupor have gradually increased, and during the past two days the patient has been almost comatose. This condition of mental hebetude was first noticed about two weeks ago.

Examination.—March 15, 1906, by Drs. Nock, Sinkler, Frazier and Spiller: Stupor is so great that the patient can be roused but slightly. She lies in bed with her head turned to the right, but there is no deviation of the eyeballs. There is no tenderness on percussion of the scalp. She is able to move the eyeballs well to the right, although there may be slight impairment of the left eyeball to the right, but probably not of the right eyeball to the left. The right pupil is larger than the left. Neither pupil reacts to light. It is impossible to tell whether there is any deviation of the tongue or to test the muscles of mastication.

Left Upper Extremity: The left extremity is very weak, although she has a little voluntary power in it and can flex the limb feebly at the elbow. She can not make a fist with the left hand. The biceps tendon and triceps tendon reflexes are present, but weak. Sensation is not disturbed.

Left Lower Extremity: The lower extremity is very weak, although she can move it slightly. The patellar reflex is present on the left side, but not very prompt. The Achilles tendon reflex is present on each side and about normal. There is no ankle clonus and the Babinski sign is very typical on the left side, as it is on the right, although not so pronounced. Pin prick is perceived in the left lower limb.

Examination of the Blood: Systolic pressure, 165; hemoglobin, 65 per cent.; white blood corpuscles, 21,240.

Urinalysis: There is slight albuminuria, no sugar and a few granular casts.

Ophthalmic Record by Dr. de Schweinitz: This examination was made a week or more before the patient came to the hospital and disclosed a moderate optic neuritis of each eye, most marked on the right side. There are also a few hemorrhages in the neighborhood of the optic disc. The neuritis appears to be in an early stage of its development; on the left side it is just beginning. The pupil reacts normally. There appears to be a divergent strabismus, usually more marked on the right side and probably dependent on paresis of the right internal rectus. Some examinations appear to indicate that there was failure in the movement of the eyeball upward, therefore some involvement of the right superior rectus. This was not certainly determined, as there did not appear to be much difference between the two sides; both lids droop to about an equal extent, but the droop is one probably due to weakness and not to paresis. The visual field, roughly taken by the hand, appeared to be undivided; at least there was no hemianopsia.

Operation.—March 15, 1906: The date the patient was admitted to the hospital an osteoplastic operation was performed, in which the motor region was exposed. It was noticed when the flap was reflected that there was some bulging of the dura at the lower and posterior angle of the opening. An exploratory incision about 1½ inches long was made at this point, at which the dura seemed very much thinner, as though undergoing atrophy from pressure. The brain contents bulged through the opening thus made, and an exploratory canula was introduced for about 1½ inches, as there was some reason for suspecting the presence of an abscess. It seemed as though the canula entered a cavity; at first some brownish fluid flowed from the canula and afterward pure blood. The exploratory incision was made about one-half inch behind the anterior margin of the opening and a small section of tissue removed for examination. Concluding the lesion was a subcortical one, we decided to discontinue any further exploration. A considerable portion of the bone in the flap was removed and the dural incisions and the incisions in the scalp closed.

From the date of the operation until the time the patient left the hospital, ten days later, the patient manifested but little, if any, improvement as a result of the operation. There were times when she seemed to be a good deal brighter than she had been in the immediate past, and also times when she had a little more movement in the left upper extremity. Mental condition, on the whole, was better, but apart from this there was very little, if any, change. It might be noted that the leucocytosis which existed before the operation continued afterward, and at one time the white-blood corpuscles numbered 36,000. In a differential count that was made March 25, 1906, there were 94 per cent. of polymorphonuclear cells. The persistent leucocytosis in the absence of any wound infection was strongly suggestive of the presence of an abscess.

Postoperative History.—May 24, 1906: A letter recently received from the patient's physician, Dr. Nock, says that her present condition is about the same. There is complete paralysis in the left upper and lower extremities, and now gradual weakening of the muscular power in the right arm and leg. When awake the patient talks intelligently and is interested in what is going on, although there is a tendency toward confusion of ideas at times. Her appetite is good and she takes enough food to maintain her nutrition. Her temperature varies from 99 to 99.3. Pulse is regular.

We include the following case, which was in the service of Dr. Mills and Dr. Martin and was studied also by us:

Case 14.—Stafford, male, aged 46, was under the care of Dr. C. K. Mills in the University Hospital in 1902. He was seen also by Dr. Potts and Dr. Spiller.

The patellar reflexes and Achilles tendon reflexes were lost; the gait was ataxic. Headache, dizziness, optic neuritis, nystagmus and paresthesia of the left side of the face were present among other symptoms. The diagnosis of cerebellar tumor was made. A palliative operation over the cerebellum was performed by Dr. Edward Martin in 1902. The patient's condition was much improved. He died in 1906 and a tumor was found in the left cerebellopontile angle (Fig. 7).

THE PRESENT STATUS OF BRAIN SURGERY.*

M. ALLEN STARR, M.D., LL.D.
Professor of Neurology, Columbia University.
NEW YORK.

It is twenty years since the first operations on the brain for the relief of tumors, epilepsy, and abscess were undertaken, and the data for final conclusions in regard to the propriety of such operations in various conditions are now available.

The enthusiasm with which these operations were performed at the outset has subsided and it is now possible to take a broader and calmer view of the entire subject; to realize the limitations of such operations; to appreciate their true value and to determine with considerable exactness the class of cases in which brain surgery promises success.

In this review I shall endeavor to present conclusions derived from an extensive experience in this field, and when statistics are cited too great stress will not be laid on them, as I realize that very many cases, both of a favorable and unfavorable kind, have not been published. I shall take up in succession the surgical treatment of epilepsy, of brain abscess, of brain tumor, of cerebral hemorrhage, and of operations for the relief of imbecility and idiocy.

I. SURGICAL TREATMENT OF EPILEPSY.

The cases of epilepsy which are open to surgical treatment are those in which it can be determined that there is a localized focus of disease in the brain, which acts as a starting point for irritation, and thus causes the epileptic attack. Such a local focus of irritation may be caused by an injury to the head, in some cases producing fracture of the skull, but in many cases not attended by external evidences of injury. It may also be produced by internal causes, such as the growth of small local inflammation of the meninges. A plaque of sclerosis in the brain, the origin of which may be wholly unknown, is capable of producing epilepsy and our experience in the treatment of abscess and tumor has shown that the necessary cutting of the brain for the relief of these diseases is liable to result in the production of gliomatous scar tissue which subsequently becomes a focus of irritation leading to epileptic attacks.

The essential difference between epilepsy produced by these local lesions and idiopathic epilepsy consists in the fact that in the cases open to operation the epileptic fit is uniformly preceded by a single kind of aura, either a sensation of numbness in one extremity, or an hallucination of sight, sound, smell, or taste, or by a sensation of muscular twitching, which is immediately followed by a localized spasm confined at first to one extremity, or to one side of the face, and extending (if it does extend) in a definite manner to the other parts of the body. The fit is rarely attended by a loss of consciousness. Such a localized epilepsy, generally recognized as Jacksonian epilepsy, is always due to a definite focus of disease in the brain. Furthermore, this disease is cortical, and hence accessible to the surgeon, and by following the well known guides to localization such diseases can be excised either from the meninges or from the cortex when these parts are laid bare.

---

*Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

It must be distinctly stated that these are the only cases of epilepsy which are open to a cerebral operation. Epilepsy is a widespread disease among the community, one person in five hundred being affected. In my experience not more than 2 per cent. of the cases of epilepsy are in any way open to operation, the other 98 per cent. presenting none of the characteristic symptoms of localized disease in the brain. It is useless to trephine in idiopathic epilepsy, even though it may have been apparently caused by a fall or blow on the head, unless the attacks present the characteristics here named.

The prognosis in the cases of focal epilepsy open to operation is not so favorable as was at first anticipated. Even when a focus of disease can be excised from the brain, a cyst removed, or a plaque of adherent meninges loosened and taken away, some cicatrix is inevitably left, and this too often remains as an adequate focus for the recurrence of the epilepsy. In only about 20 per cent. of the patients operated on has permanent cure been the terminal result. In very many cases relief for a certain time has followed the operation, but after one, two, or three years these patients have returned with a renewal of the symptoms, and second and third operations have not been followed by permanent cure. Such unfavorable results might possibly lead to the conclusion that in the majority of these cases of focal epilepsy an operation should be refused. As a matter of fact, however, it is often found that the focal epilepsy is the first symptom of the growth of a tumor, or the development of a cyst in the cortex of the brain. And if the histories of cases of brain tumor are carefully studied it is surprising to see in how many cases focal epilepsy was the earliest sign of the development of this disease. It seems imperative, therefore, to operate in these cases of focal epilepsy as soon as the diagnosis is made: First, because of the possible relief of epilepsy, and, secondly, for the possible discovery of a more serious and fatal disease just beginning.

I have had operations performed for the relief of epilepsy of a focal nature in about 60 cases. In a few of these cases conditions have been met at the operation which rendered any relief impossible. In a few of the cases (about one-fifth), a permanent cure has been obtained. In the remainder the epilepsy has returned and has been in no way affected by the operation. I have seen many cases of ordinary idiopathic epilepsy, supposed to be due to a blow on the head, operated on, the blow having left some scar that has guided the surgeon. I have never seen in these cases any tangible disease in the brain when it was exposed, and I have never seen any improvement or relief from the epileptic attacks.

A review of this experience convinces me that the operation of trephining in epilepsy is of very limited application and is only to be recommended in a few selected cases which present the necessary guide to both physician and surgeon.

Case 1.—This is a good example of Jacksonian epilepsy in which the finding at the operation justified surgical treatment.

Patient.—A boy, aged 10, began to suffer from attacks consisting of tingling and numbness beginning in the right wrist and passing up the arm, invading the right side of the face. He then felt unable to speak, would feel weak in the arm and drop anything he was holding, and occasionally he would have some twitching of the entire arm. He did not lose consciousness and the entire attack was over within five minutes. Such attacks continued at frequent intervals until the age of 23, when at my suggestion an operation was undertaken by Dr. Hartley.

Operation.—On exposure of the brain a firm adhesion between the dura, pia and cortex about the junction of the middle and lower third of the anterior central convolution was found, and as the brain at this region was manifestly hard after the membrane had been stripped off a portion of the cortex, ½x⅝ in. in size was cut out. The Faradic current was applied to the cortex in this region and produced movements of the wrist, elbow and shoulder, and above the shoulder area it caused movements of flexion of the trunk and back towards the right side; this being a complete confirmation of Sherrington's localization of the trunk centers at the junction of the middle and upper thirds of the anterior central convolution in the orang. It was evident in this case that the localized sclerosis of the cortex and adhesion of the meninges to it, probably the result of some unrecorded fall in childhood, had for many years existed as a cause for the Jacksonian epilepsy, and it was also evident that nothing but an operation would have given radical relief. I had recommended the operation when the boy was 11 years old, but it took twelve years of useless medical treatment to convince the parents of its necessity.

II. THE SURGICAL TREATMENT OF ABSCESS OF THE BRAIN.

Abscesses of the brain of traumatic origin, following injuries or fracture of the skull when located in parts of the brain, diseases of which produce definite cerebral symptoms, can usually be diagnosticated without much difficulty, and should be operated on early. In cases of fractures of the skull or concussion of the head, followed within two or three weeks by the development of symptoms suggestive of abscess, it is imperative to trephine even though the indications are purely those of a surgical kind, there being no localized cerebral symptoms, for there are many districts in the brain, disease of which does not produce known effects. Patients with abscess of the brain developing subsequently to chronic otitis media, should be operated on as early as it is possible to make the diagnosis.

The diagnosis of abscess of the brain is comparatively simple in cases in which the usual causes have preceded the development of cerebral symptoms. Headache, vertigo, vomiting, slow pulse, marked change in the mental state, sensations of dullness and hebetude, slowness of thought, irritability of temper, defective memory and depression, tenderness of the head to percussion, irregular pupils and optic neuritis, constitute sufficient evidence of a cerebral complication. When meningitis occurs, as a rule, lumbar puncture will reveal an increased number of leucocytes in the cerebral spinal fluid, and the existence of micro-organisms in that fluid. Lumbar puncture, therefore, is an important means of differential diagnosis between meningitis and cerebral abscess. Examination of the blood is also a means of diagnosis, for a sudden and great increase in the leucocytes is an indication of a cerebral complication, and the leucocyte count in meningitis is usually higher than that in abscess. As soon as the diagnosis of a cerebral abscess is made, under any circumtances it is imperative to operate. And while the percentage of recoveries from the nature of the case is at present only about 60 per cent. in statistics I have collected[1] covering about 500 cases, yet there is every reason to believe that in cases that are diagnosticated early and the operation is undertaken as soon as the diagnosis is made, the percentage of recoveries will be much greater.

III. THE SURGICAL TREATMENT OF TUMORS OF THE BRAIN.

The diagnosis of brain tumor is usually easy from the combined presence of headache, worse on waking, vomiting of a projectile type, not connected with the taking of food, and worse on waking, vertigo developing on change of position, optic neuritis and mental dullness. When to these symptoms there are added either Jacksonian epilepsy, paralysis at first limited to one limb and extending to other parts, some form of aphasia, hemianopsia, astereognosis, cerebellar staggering and sudden loss of balancing power, or the combination of cranial nerve symptoms due to involvement of the tissues on the base of the brain, the diagnosis of the position of the tumor is reasonably certain. In these cases operative interference may be warranted. In the far larger number of cases in which localizing signs are absent operation promises nothing.

A careful review of a large number of cases of brain tumor, examined postmortem, shows that about 10 per cent. of tumors are open to surgical treatment. The most recent statistics of results in such cases have been published by Dr. Philip Coombes Knapp,[2] whose tables I reproduce, as they are most instructive. Of 828 tumors operated on up to July, 1905, it was found that in 471 cases the tumor was found and removed; in 189 cases the tumor was not found, in 104 cases the operation was a palliative one only, and in 64 cases the tumor, though found, could not be safely removed. Further analysis of the cases, 471 in number, in which the tumor was removed, shows that the diagnosis was correct, the removal easy, and the recovery or improvement most satisfactory in those cases in which the tumor lay near the Rolandic or Sylvian fissures, while the mortality was greatest in the cerebellar cases.

RESULTS IN OPERATIONS FOR TUMORS OF THE BRAIN.

	Recovered.	Improved.	Not improved.	Died.	Result not stated.	Total.
Removed	112	122	78	123	36	471
Not found	4	24	61	87	13	189
Impossible	0	11	11	40	2	64
Palliative	0	48	36	15	5	104
Total.	116	205	186	265	56	828
Frontal	15	6	3	8	2	34
Central	52	82	43	54	5	236
Parietal	7	5	5	12	0	29
Temp.	2	4	6	5	1	18
Occip.	3	3	2	2	1	11
Cerebellum	7	16	8	23	1	55
Not stated	26	6	11	19	26	88

These statistics are quite in accord with my own experience. It is evident then that out of 100 brain tumors we may expect success in surgical treatment in but five only. Yet there is no doubt that even if the number of lives saved is small it is our duty to study every case with our minds fixed on the question of possible surgical relief.

It has been proposed by Horsley and recently urged by Cushing, that in inaccessible tumors some relief of symptoms may be attained by making a large opening in the skull for the relief of pressure. In one of my patients recently operated on by Cushing the removal of two portions of bone over both lobes of the cerebellum, has apparently cured the child, the blindness has subsided, the headaches have ceased, and although he staggers some still in walking, he lives in comfort and is able to go to school, while at the time of operation in July, 1905, he was at the point of death. Such cases encourage one to believe that palliative operations are justifiable. It is only right to state that I have seen two other cases in which they did not succeed.

Case 2.—This case shows the importance of early operation in brain tumor.

Patient.—In January, 1905, a healthy business man began to suffer from severe frontal headaches, sometimes attended by vomiting, and it was soon noticed that he misplaced words and had difficulty in expressing his ideas. These symptoms increased steadily during February, and early in March he had a temporary attack of right hemiplegia and aphasia, which, however, passed off entirely in two days, but left his speech more defective. This was followed by recurring attacks of twitching in the right hand and in the right side of the face, attended and followed by numbness in these parts. By the middle of March his speech defect had become constant an he could no longer write, though he could read; and he had become very dull and drowsy.

Examination.—On March 25 he went into a semi-stuporous state in which I first saw him. I found an extreme choked disc in both eyes, worse in the left; no paralysis, but a flatness of the right side of the face and increased reflexes in the right limbs. I concurred in the diagnosis of brain tumor made by his physician, Dr. Rutz, and located the tumor in the left third frontal convolution, and recommended operation.

Operation.—On March 27 Dr. Hartley operated, making a large bony flap over the left ear four inches in diameter. When the dura was opened the tumor was visible, lying in the middle of the third frontal convolution. It was easily shelled out by a spoon, and some small discolored parts of the white matter of the brain about it were also taken out, leaving a clean cavity.

His recovery was rapid. The day after the operation he was still speechless, but within a week he had regained his speech, could read aloud, and could write, and had no paralysis. On April 16 he was up and the wound had healed. On May 16 he went back to business in apparently good health. In November, 1905, he had had no return of brain symptoms.

IV. SURGICAL TREATMENT OF CEREBRAL HEMORRHAGE.

In cases of extradural hemorrhage following contusions or fracture of the skull the slow development of symptoms of intracranial pressure, slow pulse, steady rise in the blood pressure, deepening coma, Cheyne-Stokes respiration, and increasing hemiplegia, afford sufficiently clear indications for trephining. The symptoms develop within six hours of the injury. It is usually from the middle meningeal artery that the hemorrhage occurs; hence it is the area just above the ear which is to be exposed, a large trephine opening or a large bony flap being made. All surgeons of experience have treated such cases successfully, and the literature is full of reports of clots removed, with recovery.

It requires much courage to suggest an operation in the head in a patient who is comatose from an apoplexy. A considerable number of these patients recover, at least in part, when left alone, and the depth of the coma, or the degree of the paralysis affords no indication during the first twenty-four hours, of the eventual result. It is due to Harvey Cushing to state that he has applied successfully in hospital cases the test of the condition of the pulse tension in determining the need of surgical intervention to prevent death. When the blood pressure

---

2. Knapp: Boston Med. and Surg. Jour., Feb. 1, 1906.

rises steadily to 250 mm., measured on the Riva Rocci apparatus, in a case of apoplexy, and coincidently with this rise there is a slow pulse falling to 50 a minute, we may say that the case will be fatal. It is in such a case that we are justified in resorting to surgery.[3] The object in view is to relieve the intracranial pressure. This is to be done by turning down a large bony flap or making a large fenestrum in the skull, irrespective of any attempt to find or to remove the clot. The best place to open is over the motor area on the side opposite to the paralysis, for in some cases the clot may be found there. The dura is to be exposed and divided. If the clot is on the surface it will then be seen. If the clot is within the brain the brain will bulge and division in the depth of a fissure may succeed in reaching and evacuating the clot. Even if the clot is not found and removed the relief of the intracranial pressure stops the alarming symptoms and recovery is much hastened, as Cushing's cases have proved. The pulse tension falls as soon as the skull is opened. The pulse becomes more rapid, Cheyne-Stokes respiration ceases, and consciousness soon returns. The operation thus saves life in a formerly hopeless condition.

There is another class of cases of cerebral hemorrhage n which Cushing has also operated successfully. A cerain number of infants are born in a state of asphyxiaion. and it is evident that the delayed or difficult labor has caused not only a large caput succedaneum, but an intracranial hemorrhage, either extradural or intradural. Lumbar puncture usually shows a bloody cerebrospinal fluid in these cases. These infants usually die, or if they live they will remain hemiplegic, idiotic, or epileptic all their lives. a burden to their families or to the community. Any measure for their relief is justifiable. It is comparatively easy in a newborn infant to expose the brain by opening the sutures of the parietal bone with scissors. This operation has been done in asphyxiated paralyzed infants. when the ordinary methods of resuscitation have been applied in vain; large clots. both extradural and intradural, have been found and removed, and recovery has followed. The child's life is saved and the brain in its gradual development throws off the effects of the temporary pressure.[4] It seems true that the success of Cushing in these cases warrants us in urging on obstetricians their duty to consider this operation in asphyxiated infants. It is they who see these cases, and if they can be persuaded that delay in them is dangerous, and the prospect of relief is good, the percentage of idiocy and hemiplegic epilepsy will surely be reduced.

The last class of cases of cerebral hemorrhage open to trephining is the class in which the hemiplegia or aphasia or hemianopsia develops slowly after an injury and does not come to its height for three or four days. In these cases it is probable that a surface hemorrhage has been due to the injury of a vein of the pia mater. A lumbar puncture will reveal bloody cerebrospinal fluid. The symptoms may increase and threaten life, as shown by the slow pulse, Cheyne-Stokes respiration, and increasing blood pressure, or they may come to a standstill. leaving the patient permanently incapacitated. In either case surgical treatment is indicated. I believe the case reported by Dr. McBurney and myself in 1889,[5] of the successful removal of a clot from the lower third of the fissure of Rolando, was one of the first of this character. The man was a physician who was thrown from his buggy, and in the course of three days after developed a motor aphasia and right hemiplegia. The operation was done four months after the injury. The clot was found semifluid and organized, and was easily taken out. His recovery was progressive, and he eventually returned to his practice, though he remained slightly hemiplegic until his death in 1897. I could cite many other cases equally successful.

V. SURGICAL TREATMENT OF IMBECILITY.

It will be remembered that much interest was excited as far back as 1891 by some results reported by Lannelongue in which he had attempted to cure imbecility due to microcephalus by making large exsections in the skull and thus allowing for an increased expansion of the brain. A wide segment of bone was cut from the frontal through the parietal to the occipital region on both sides, and in some cases the parietal bones were pried out a little, thus giving ample space for the brain to grow. Lannelongue reported these cases from the surgical standpoint as recoveries, intending to imply that the children had survived the operation. It was mistakenly supposed that he had implied an improvement or recovery from the condition of imbecility, and hence his operation was repeated by many surgeons in many lands—Dr. Keen in this country and Dr. McBurney and I having done a number of such operations. The subsequent histories of these cases, however, has demonstrated conclusively that no marked mental improvement ever follows this operation. It is evident that the microcephalus is not the cause of the imbecility, but that the imperfect and rudimentary development of the brain, which does not grow in proportion to the rest of the body, prevents the normal expansion of the skull over a normally growing brain and leads to an early closure of the fontanelles, though, as is well known, such a closure in no way affects the growth of the size of the head in a normal infant, granting that the brain within it be normal. All imbeciles improve gradually under proper instruction as they grow older. In some cases they even develop rudimentary speech spontaneously, hence the slight improvement which in some cases has appeared to follow the operation in no way differs from a corresponding improvement in patients equally affected but equally trained, who have not been operated on.[6] For this reason I no longer recommend any operation on the head in cases of idiocy, imbecility, hemiplegia and epilepsy dating from childhood, and it may be stated incidentally that these operations have no effect whatever on the painful condition so often associated with these conditions, namely, athetosis.

I may record one case in particular in which a hemiplegic child with very extreme athetoid movements in the paralyzed limbs was operated on by Dr. McCosh at my suggestion, and a thick organized clot, more of the nature of a thin connective tissue membrane was stripped off from the motor-centers of the arm and leg without any subsequent benefit either to the hemiplegia or to the athetosis. In two other cases of the same nature in which operation was performed, a peculiar connective tissue structure was found occupying the motor zone of the cortex, which resembled in appearance honeycomb, the interstices being filled with serum. The removal of this structure which was regarded as the terminal organized relic of an early hemorrhage, produced absolutely no permanent cure in the child's condition.

...of pulsation is very interesting. He did not
...lly agree with Dr. Dercum that the absence of pulsation is due to increased intracranial tension. He has seen cases in which there was absolutely no pulsation of the brain over the tumor and in which the pulsation was around the edges of the tumor. This was the very best indication that the tumor was there. In one case there was a subcortical tumor two or three inches deep, and there was the absence of pulsation, which was an indication that there was a tumor below the cortex. On the other hand, sometimes there is normal pulsation of the brain, in, around and above the tumor. Therefore, tumors may exist with pulsation, and they may exist without pulsation, and it is not possible to make any definite statement with regard to the presence or absence of tumors from the condition of pulsation of the brain in operations.

Dr. W. G. Spiller, Philadelphia, said, in regard to Dr. Mills' statement that the location should be accurately determined and the skull carefully measured, that he knew of an instance in which the tumor was missed by a quarter of an inch, owing to its being inaccurately localized. He was rather doubtful of the value of operation for removal in cases of glioma. He doubted if there is much benefit to be expected from the attempted removal of glioma, and whether the patient would not have lived as long, if not longer, without radical operation, as he believes there is a tendency of the glioma to grow faster after partial removal, for it becomes congested, better supplied with blood, and space is afforded for its growth. In one of the cases under his own observation, relief for a time was obtained by repeated operation. It is, however, almost impossible to distinguish at operation a glioma from a sarcoma. The former is infiltrating and it is probably impossible to remove the whole of the tumor. In one of the cases reported in which symptoms suggestive of brain tumor were present, a sudden gush of fluid occurred from the nostrils, possibly through the cribriform plate of the ethmoid bone, and afforded great relief. It seemed to be a palliative treatment by natural means. Dr. Knapp spoke of his very hopeful views. He tried to be conservative; if he was hopeful, it was because in the majority of cases palliative operation had been of benefit. By no means, did he believe that in every case there will be marked improvement. He is in favor of the dura being opened in every case of palliative operation. It should not be left open, nor should it be cut away, but it should be opened and the brain examined to see if there is any tumor. Recently he had seen a small tumor, half an inch in diameter, that could easily have escaped detection.

...stal end of the jejunum be attached as it naturally lies that it may at once drop to the left and posteriorly in its normal anatomical position.

The operation thus briefly outlined has a nominal mortality. We had but 1 death in 135 "no loop" operations. The anterior method preferably with a Murphy button or McGraw ligature, is occasionally demanded by reason of posterior adhesions or abnormalities in the meso-colon or duodeno-jejunal juncture; but as it sacrifices 18 to 20 inches of the most important part of the upper jejunum it can not be considered a close rival to the posterior operation. We have for the past year and a half abandoned all "loop" operations unless forced to them and in no case practice enteroanastomosis as a primary procedure. Of the total 600 gastric and duodenal ulcers 383 were subjected to gastrojejunostomy (64 per cent.).

The question arises—What results can be expected from gastrojejunostomy? In the early stages of any subject certain procedures gain a great reputation which later experience does not always bear out. While gastrojejunostomy is by all odds the most useful means of relief it is not a cure-all. It is purely a drainage operation and as in a large majority of cases the ulcers are situated in the grinding pyloric end of the stomach or upper duodenum, the alleviation afforded is certain and speedy. But if the lesion does not involve permanent interference with natural drainage the food will eventually pass out the normal opening rather than the gastrojejunostomy and a certain amount of shrinking of the anastomotic stoma or angulation may follow.

The dangers from this source are reduced to a minimum with a "no-loop" operation. The more serious the interference with the normal motility the greater the relief afforded by gastrojejunostomy, so that for indurated ulcer it is the method "par excellence." On the contrary in mucous lesions where the interference with gastric drainage is intermittent and due to muscular spasm the results are less certain.

GASTRODUODENOSTOMY.

The only operation on the stomach of any consequence which involves a new principle in surgery since the time of Billroth is that of Finney. It leaves the opening at the natural situation and the enlargement is downward along the greater curvature away from the ulcer area. Gastroduodenostomy is especially applicable to those mucous lesions which interfere with drainage through spasm. It supplements gastrojejunostomy admirably as its scope includes those cases in which the latter method has been less certain of cure and it has superseded pyloroplasty. We have had 72 cases with 4 deaths and the very large majority of those who recovered have remained well.

EXCISION OF THE ULCER.

Theoretically, excision of the ulcer is the logical procedure but it must be shown by careful examination that the one excised is the only one present.

The saddle ulcer of the lesser curvature, if it does not interfere with drainage, should be excised if practicable because, as has been pointed out, if the stomach is not dilated and the pylorus is open, muscular action will continue to force the food along the normal channel rather than out of the artificial stoma. Therefore, a direct attack on the diseased area under such circumstances, especially when the margins of the ulceration are hard and calloused, would seem to be sound practice. We have excised ulcers 14 times, 6 times of the lesser curvature and 8 times in connection with pyloroplasty and gastroduodenostomy, with no deaths.

RODMAN'S OPERATION.

Some four years ago it was suggested by Dr. William L. Rodman that as ulcer of the stomach in the large majority of instances was in the pyloric portion it would be wise to resect as one would do for cancer, closing both duodenal and stomach ends completely and reestablish the gastrointestinal canal by an independent gastrojejunostomy. We have performed this operation nine times with great satisfaction. All of the cases recovered and have remained well. It has its chief indication in indurated lesions in the vicinity of the pylorus.

RESECTION OF THE STOMACH.

The treatment of hour-glass stomach by some form of plastic gastrogastrostomy has been a popular operation but in the majority of instances the ultimate results are unsatisfactory as it leaves a large amount of scar tissue and if it happen that the pylorus is involved to any extent adequate drainage is difficult to secure.

Gastrojejunostomy on the proximal pouch does not prevent a certain amount of food passing into the distal loculus where it stagnates on account of loss of motility. Multiple gastrojejunostomies, one for each loculus with enteroanastomosis beyond, is an unnecessarily complicated procedure, especially if more than two loculi are present.

We have in 12 cases without a death resected the affected portion of the stomach in the following manner (Figs. 2 and 3): The gastrohepatic and gastrocolic omenta are divided and separated from the diseased area, a straight elastic holding clamp is placed on the proximal side across from the greater to the lesser curvature about one inch back from the proposed line of resection. On the distal side the clamp is applied obliquely from above down, right to left, to increase the diameter of the cut surface, saving from the greater curvature. In this way we have been able to secure on the distal side an opening two-thirds the size of the proximal one for suturing. By having one inch or more of the tissue projecting beyond the clamps the slack on the large or proximal side is taken up with each suture, the bite of the thread taking only two-thirds of the amount of tissue on the distal portion, a difference of diameter of one-third being disposed of in this manner without seam or noticeable pucker.

If the ulcer is situated close to the pylorus an end-to-end union is quite easy to obtain. In two cases we have been able to excise an ulcer of the duodenum close to the pylorus with direct union of the amputated end of the duodenum to the stomach, the pylorus being removed in both instances.

The last word on ulcer of the stomach has not been written and it is evident that no one operation will be applicable to all varieties. At the present time it would seem that gastrojejunostomy has the largest field of usefulness, especially in those cases in which there is permanent interference with gastric mobility by reason of obstructive lesions in the pyloric end.

For those cases in which obstruction is due to spasm or other non-mechanical cause the gastroduodenostomy of Finney is the operation of choice. In connection with this latter procedure the excision of an ulcer of either the stomach or duodenum in close proximity to the pylorus may be done with great satisfaction.

Gastric ulcers which do not interfere with drainage and in which there is no loss of motility should be directly excised if possible.

Calloused ulcers of large size and thick hard margins whether hour-glass or not, are best treated by some form of gastric resection as we have frequently found carcinomatous degeneration taking place.

The large majority of duodenal ulcers give indication for gastrojejunostomy. There are few exceptions in which excision or resection will give better results.

It can be shown that more than 90 per cent. of patients suffering from gastric and duodenal ulcer who have been subjected to operation have been cured. Failures are more often due to technical errors resulting in bad mechanics than to the inability of a properly executed operation to cure the disease.

To one who expects to practice surgery of the stomach we would strongly recommend a close study of the gastric manifestations of the neurasthenic state. Atonic dilatations, prolapse of the stomach and the various gastric neuroses may simulate ulcer very closely and a careful differentiation is absolutely essential for all of these latter conditions are unimproved and often accentuated by operation, bringing discredit on surgery as a whole.

DISCUSSION

ON PAPERS OF BILLINGS, LAMBERT, RODMAN AND MAYO.

Dr. John C. Hemmeter, Baltimore, stated that the recognition of gastric ulcer depends very largely on the exercise of the sixth sense. It is largely a diagnosis by exclusion. Recently he reported before the American Gastroenterological Association *a method of diagnosing gastric ulcer* which he hopes to be able to lift out of the sphere of speculation into that of absolute recognition and surety. He had a number of surgeons make experimental ulcers in dogs by removing the gastric mucosa. The incision was allowed to heal, and a suspension of bismuth subnitrate in 500 c.c. of water was placed in the dog's stomach, the dog being placed in the posterior position. He found that eight to ten hours afterward the bismuth could be recognized by means of the *x*-ray and the fluoroscope. In a case of very severe gastric hemorrhage in a human patient, whose stomach had been washed out with bismuth subnitrate and ice water, it was found at the necropsy by Recklinghausen that the bismuth had everywhere disappeared, except from the site of the gastric ulcer. There seems to be a peculiar form of exudate in ulcer which holds the bismuth, and the latter is shown plainly by the *x*-ray. In three instances he succeeded in diagnosing ulcer by this means. The patients were operated on and the ulcers were found. If the ulcer is located behind a rib, the rib will obscure the ulcer. Dr. Hemmeter stated that at times it is very difficult to differentiate between gastric ulcer and gallstones. There is not one symptom of cholelithiasis that does not occur also in gastric ulcer. The patient may even have jaundice in gastric ulcer and hemorrhages in gallstones when there is no ulcer present. To narrow down the diagnosis between gastric ulcer and gallstones, he advised giving eight grains of orthoform in one ounce of hot water. It will arrest the pain if it is due to gastric ulcer, but not if it is due to gallstones. As to the treatment, Dr. Hemmeter is convinced that the uncomplicated gastric ulcer is no object for surgical treatment. It is only when complications arise that more strenuous measures in the way of surgical intervention are indicated. When there is a perigastritis, or a stricture due to a cicatrix, a perforation, an intractable hemorrhage, in cases of persistent excess of hydrochloric acid, when there is a progressive atony of the stomach, then the patient should be operated on because there is something at the pylorus that is preventing the exit of food.

Dr. Max Einhorn, New York, thought at one time that all cases of pyloric obstruction had to be operated on. Among eight of his first patients operated on, four had to be treated medicinally for quite a while after the operation, and two died. This made him a little backward about recommending the operation; because the patient can get along tolerably well without operation, this procedure should not be recommended until the stage is reached where there is nothing else to be done. If the operation could be done without danger, with no mortality at all, then he would urge that all cases of pyloric obstruction be operated on, but not otherwise. As a matter of fact, benign pyloric obstruction, if not too far advanced, can be greatly ameliorated, and sometimes cured, by rational medical treatment.

Dr. A. P. Francine, Philadelphia, has been particularly interested in the incidence of gastric ulcer as found at autopsy. From the analysis of over 3,800 consecutive postmortems held at the Philadelphia Hospital, he found that chronic gastric ulcer occurred in 1.35 per cent. of the cases. This figure is almost identical with that obtained by Dr. Campbell Howard, of Baltimore, from a similar study. But Dr. Francine is inclined to believe that there may be error in figures gleaned even from this source, and this percentage is, if anything, too small. This comes about from the fact that a certain number of chronic ulcers heal and leave no scars, or the scars are so slight as to be overlooked in routine work. It is also true that small ulcers with minute openings on the gastric mucous membrane, which might during life have given rise to very definite symptoms, may in a similar manner be overlooked unless careful search is made for them. The great majority of acute ulcers heal and the diagnosis of acute ulcer rests with the clinician. Chronic ulcer is, as a rule, chronic from its inception. For the above reasons he feels that a fairer percentage, even for chronic ulcer, would be 1.50 per cent., or about three in every two hundred autopsies.

From the above studies Dr. Francine was much struck by the presence of tuberculosis and nephritis in these cases. In 76 per cent. of the autopsies these conditions were associated, and he was inclined to feel that in some way, possibly by reducing the general nutrition, and particularly the nutrition of the stomach, thereby creating a more favorable nidus for the action of the more direct or exciting causes of ulcers, tuberculosis and nephritis might be indirect factors in the etiology. With a larger experience, however, he has come to modify this view and to look on them as playing little, if any, part in the etiology. For of one hundred and forty-three cases of advanced pulmonary tuberculosis dying at the Phipp's Institute, in Philadelphia, there was not a single case of true gastric ulcer. In one case there was multiple, superficial ulcerations, evidently tuberculous.

As to why tuberculosis does not more frequently affect the stomach, Dr. Francine thinks it possibly owing to the powerful motor action of the stomach in rapidly passing on the contaminated food and sputum mass, and it is probable, too, that the glandular action of the stomach plays an important rôle in both hydrochloric acid and pepsin secretion. Clinical records of the incidence of gastric ulcer are, in general, subject to such error in diagnosis that he considers them of comparatively little value in estimating its true frequency. One condition which has come under his observation and which may lead to confusion is the hemorrhagic tendency or diathesis manifest in certain chronic dyscrasic diseases. He has known this to lead to error in cases of chronic nephritis, where antemortem there were definite symptoms simulating gastric ulcer, associated with the vomiting of pure blood, and yet at autopsy no sign of ulcer was found. Discounting, however, errors in diagnosis, he thinks that gastric ulcer is much more common clinically than pathologically.

Dr. Stanley P. Black, Pasadena, Cal., said that there is one test used extensively in the past, but which has been given up largely at present, and unjustly so, and that is the occurrence of peptonuria or albumosuria. Albumoses occur in the urine from ulcer in any part of the intestinal tract. In certain cases this may be of importance in arriving at a diagnosis, especially in obscure cases of gastric ulcer. He differed with Dr. Billings as to the advisability of putting the test for occult blood last. He would put it first, because it is a most important test; it is the test of last resort. Therefore, it is better to make that test first. The presence of occult blood in the stomach contents or feces does not mean necessarily gastric ulcer, but it is one found present almost invariably in gastric ulcer.

With reference to the treatment of this condition. Dr. Black would do as in any other case of ulcer, place it absolutely at rest; that is, keeping the stomach in an empty condition, excluding even ice, and relying entirely on rectal injections for nourishment. The physician ought to have a competent surgeon in consultation in every case to share the responsibility and to decide when surgical intervention is necessary. He believes with Dr. Rodman that excision is the ideal operation, but the technic of the surgeon is not perfect enough to avoid the great risk. However, the ideal operation of the future, the operation of the coming surgeon, will be complete excision of the ulcer and the entire ulcer-bearing surface.

Dr. John C. Munro, Boston, referred to 250 cases operated on at the Carney Hospital. Of these, approximately 70 were malignant, a half dozen only coming early enough for radical operation. The remaining cases were benign, and for these different types of operation were performed. In the typical gross ulcers the results have been so satisfactory that there is no longer any question in his mind as to the advisability of surgical treatment. Occasionally there occurs a disappointing result, the reason for which is not yet clear. For instance, in two cases of duodenal ulcers for which he performed a posterior anastomosis, there followed a perfect, immediate and persistent relief of all symptoms. Suddenly, at nine and fifteen months respectively, a sudden hemorrhage took place, from which one of the patients died. The fatal case was operated on by Roux's method; the other by Moynihan's. Progress up to the time of the recurrent attack was all that could be desired. It is only possible to speculate as to the true pathologic cause. Peptic ulcer comes to one's mind, first of all.

As to the type of operation. In the gross lesions Dr. Munro prefers the no-loop operation, as recently described by Mayo, and as used by him before Mayo established its logical value. These cases have remained complete successes, one of them being a congenital pyloric stenosis. Moynihan's method has proven far less satisfactory than either Finney's or Mayo's. The results from Finney's operation, when used judiciously, have been good, although the immediate benefit is slow to show itself, and for a while may lead to disappointment. Later reports from patients are reassuring and he has returned to this method for certain cases.

Dr. Munro has tried every type of operation on about 20 so-called neurotics, with, for the most part, visible, but insignificant evidences of past lesions, but without definite mechanical interference with the stomach functions. Almost without exception the results of drainage, no matter what method was used, have been disappointing or even fatal. The pathology of those cases is obscure. He thinks some are probably types of hysteria. Others are not wholly explainable on that hypothesis. The pathologic department of Harvard is working in conjunction with the hospital staff on these and other cases, and they hope soon to obtain some definite data that will help to clear up the confusion that surrounds this class of sufferers. Careful preliminary analyses and examinations do not clear up the diagnosis in many of them. If, at exploration, no sufficient cause for the symptoms is found, even though the relics of old-healed ulcers are discovered, he abstains from doing anything to modify the drainage of the stomach. Dr.

Munro is inclined to believe that it is this type of case, pathologically speaking, which gives the brilliant results obtained by medical treatment. He questions whether similar results are ever obtained in the medical treatment of gross infiltrated ulcers.

Dr. John M. Finney, Baltimore, referred to a surgical procedure suggested by him a few years ago, namely, pyloroplasty, a term to which some objection has been raised. The operation is essentially a gastroduodenostomy, but it has to do really with the enlargement of the pylorus. There are other methods of gastroduodenostomy, e. g., Kocher's subpyloric method, but the essential principle in Finney's operation is the enlargement of the pylorus itself. The proper term would be gastro-pyloro-duodenostomy. But on account of the length of the name he decided to retain pyloroplasty. His experience with this operation in the four years since he first performed it has been confined to thirty-five cases. He has used the method in all cases that have come under his care in which he felt justified in using it. In many cases he made use of other procedures. Of these thirty-five cases, two are of such recent occurrence, being still in the hospital, that he has eliminated them from the statistics. Therefore, only 33 cases are cited. Of these, four patients died. Autopsies were secured in these four cases, and in none of them could death be attributed to the operation. The first patient was a diabetic, who died on the fifth day after the operation from diabetic coma. The next patient was tuberculous, and in the fourth week after the stomach symptoms had been relieved by the operation, died of pneumothorax, developed while still in the hospital. The third case was one of those interesting cases of gastromesenteric ileus. The fourth patient was pregnant. Some days after the operation she developed a grave toxemia from which she died. Autopsy showed no peritonitis, but an intensely fatty liver.

The results, so far as the operation itself is concerned, in all the cases shown by the autopsy, were entirely satisfactory. Those cases in which Dr. Finney performed the operation cover practically all the conditions which one meets with in connection with acute and chronic ulcer. Of acute ulcers there were five cases: three were bleeding at the time. Four recovered and are well. One he has not heard from. The end results have been traced in all but two of the cases. Of healed ulcers, where there was simply a stenosis, he had sixteen cases. Of these he has heard from all but one. The others are all well.

Of dyspeptics there were nine cases; four well; one improved; two died; one not heard from, and one too early to report on. Of the obstructions where gastrosuccorrhea was present, there were two cases. Both patients are improved. In the large class of neurotic cases Finney performed six operations, against his protest in four cases. Three were unimproved. One has been improved up to the point where she is able to live in comfort.

Dr. D. S. Fairchild, Clinton, Ia., thought that the history of ulcer of the stomach in the future must be somewhat different from what it has been in the past. The early diagnosis of ulcer of the stomach has been shown to be difficult, only those who are skilled in diagnosis are able to determine with any degree of accuracy the existence of ulcer until certain organic changes have taken place in the stomach, such as contraction of the pylorus. In the future, when the diagnosis is made earlier, the statistics will be changed on account of the fact that a large number of cases will be distinctively medical. In the West the cases have not been regarded as ulcers of the stomach until the disease has become chronic, and then it has been too late for medical consideration. A very large percentage of these cases must be surgical in their character. Therefore, with earlier diagnosis in the future more of these cases will be medical ones. The fact of surgeons accepting medical treatment of ulcer of the stomach is based on the failure to find anything pointing toward chronicity or any considerable degree of contraction of the pylorus. When the stage of chronic ulcer of pyloric contraction is reached, then surgery must be resorted to.

Dr. Fairchild believes that ulcer of the duodenum is more distinctively a surgical condition than is ulcer of the stomach, because the walls of the duodenum are thin, and it often happens that symptoms are not very distinctive until the very dangerous condition of perforation has arisen. Therefore, it seems that the rule in the treatment of ulcer of the duodenum should be different from the rule in the treatment of ulcer of the stomach on account of these serious dangers arising in an unexpected manner.

Dr. C. S. Williamson, Chicago, called attention to the fact that a considerable number of ulcer cases run their entire course with almost the precise symptoms of the most frequent neurosis of the stomach, namely, hyperchlorhydria. In this group of cases there is no pain after eating, but, on the contrary, a sense of discomfort one or two hours after eating, often relieved on taking food or some alkali. Again, the tender spot so characteristic of ulcer may be lacking. There is instead a diffuse hyperesthesia over the entire stomach area. The dorsal pain point also is lacking. In fact, a considerable number of cases of ulcer of the stomach may run their entire course without any symptoms, except those of hyperchlorhydria. This is important because there is absolutely no way of making a diagnosis in the early stage in these cases, excepting by the presence of blood in the stool, the presence of blood in the gastric contents being of much less importance owing to the possibility of trauma from the stomach tube. Dr. Williamson urged that in this group of cases one should never omit to examine by means of the Weber test for occult hemorrhages. The persistent presence of occult hemorrhages, coupled with the symptoms already mentioned, make a diagnosis of ulcer of the stomach in the highest degree probable, although by no means certain. Occult hemorrhage is not a pathognomonic symptom, but simply one which adds greatly to the probable correctness of the diagnosis. A case coming under observation early, with persistent symptoms of hyperacidity and the repeated occurrence of blood in minute quantities in the feces makes the diagnosis of ulcer highly probable.

As to the negative significance of occult hemorrhages, almost no number of examinations for occult blood justifies a positive conclusion. On more than one occasion examinations were made repeatedly, two or three times a week, without finding any blood, and yet ulcer was present. In one case seventeen negative examinations were made, and the eighteenth was strongly positive. So that it is clear that every ulcer does not bleed, at least not at all times. If it does bleed, then it is a distinctively positive sign. If, on the other hand, occult hemorrhages are not found, then we should not jump at the conclusion that ulcer is absent. We should examine repeatedly and continuously. The situation is exactly the same as for examination of tubercle bacilli in the sputum. No number of negative examinations have any great weight, unless they are made with the greatest care and thoroughness and under the most favorable conditions, and even then the examination is never conclusive. There are a few cases where the Weber test, a very reliable test, will leave one in doubt. Under those circumstances one should never fail to make a corroborative test. The best corroborative test in Dr. Williams' judgment is the modified hemin crystal test of Strzyzowski.

Dr. A. J. Spivak, Denver, speaking of the treatment of gastric ulcer, especially the test treatment, said that not even water should be allowed, because water is also expelled from the stomach by peristaltic action, and, therefore, the ulcerations will not be benefited. In fact, to secure absolute rest of the stomach not even nutrient enemata should be given because they also produce peristalsis of the intestines, if not of the stomach, and peristaltic movements of the intestines produce a certain vibratory movement of the stomach, and, therefore, absolute rest of the stomach is not secured. Dr. Spivak does not understand why we should try to give these patients food. It has been seen from Dr. Ochsner's treatment of appendicitis that a patient can live ten or even twenty days without a particle of food. Why then should we want to give these acute ulcer cases food or anything at all that will irritate the whole or any part of the gastrointestinal tract of the patient. He is positive that we should have had greater and better results if the appendicitis treatment of Dr. Ochsner would be carried out, not only by not giving food by stomach, but also not by the intestines, in any case of acute gastrointestinal disorder.

Dr. George W. McCaskey, Fort Wayne, Ind., stated that he considered the work of Dr. F. B. Turck to be the greatest advance yet made in working out the pathology of gastric ulcer. Not only that Dr. Turck succeeded in producing typical ulcers by the feeding of colon bacillus cultures to dogs, but he has obtained this result not as an exception, but with remarkable uniformity in a large number of instances. If the histologic changes which Dr. Turck showed are to be credited, then we must minimize the importance of the gastric juice as an early factor in the production of gastric ulcer, because his examinations showed that the initial process is not one of self-digestion, but that it is one of autocytolysis. Dr. McCaskey has no doubt of the correctness of Dr. Billings' conclusion that the gastric juice is one of the principal factors in the grosser and later changes of gastric ulcer, but in the early changes it seems probable that the process is one of autocytolysis and not one of digestion.

He does not believe that it is safe to lay down a hard and fast rule in the matter of early feeding in gastric ulcer. He referred to two series of cases occurring in the Massachusetts General Hospital. In one series no food was given for some time. In the other series feeding was started almost immediately, and the difference in results was very small, indeed. The proper thing to do, he said, is to individualize the cases; to discriminate; to study. Take, for instance, a patient suffering from repeated hemorrhages. The emaciation may be extreme; the nutritive processes at the lowest ebb, and reparative processes can not go on in ulcer anywhere under such circumstances. Therefore, he believes, that in many cases we ought to feed these patients at once in order to restore those properties and constituents of the blood which permit the reparative processes to go on. He is generally in favor of the routine treatment of starvation for a limited period of time, with rectal feeding and the gradual use of stomach feeding later on, but in some cases the nutritive processes are so low that the patient should be fed even at some hazard.

With reference to the use of the stomach tube, he is highly in favor of its use in all cases where there is persistent débris in the stomach. It is absurd to talk about giving rest to a stomach that is full of débris and irritating secretions. Every day or, at least every other day, we ought to cleanse the stomach; and then introduce a bismuth suspension. The mortality from gastroenterostomies, he thinks, does not express all of the hazard and injury incurred from such an operation. He is heartily in favor of operation in properly selected cases, but it seems among other things that objections to adhesions formed between the stomach and bowel must cripple the peristalsis of these organs ever afterward.

Dr. W. E. Anderson, Farmville, Va., referred to a case of acute gastric ulcer occurring in a young woman to show what rest can do. After persistently trying various remedies recommended and accomplishing but little, he determined to stop all medicines and to give the stomach complete rest. He allowed no food or water in the stomach for twenty-one days, but during that time saline enemata were given to supply the body with necessary liquids, and also nutrient enemata every eight hours. The patient began to improve promptly under this treatment. On the twenty-first day a little hot water was given by mouth, but it was returned promptly. Dr. Anderson then concluded to let the patient wash out her stomach herself with a quart of saline solution twice every twenty-four hours. After a day or two the fluid was returned clear and the patient is on the road to recovery.

Dr. William H. Wathen, Louisville, Ky., referred to the error in the statistics of gastroenterostomy by the internists who oppose the operation to the extent that the surgeons advise it. He said we are as yet too young in the work of gastroenterostomy to draw accurate conclusions as to what will be in the future the ultimate or final results from this operation. This operation was performed but relatively a few times until about five years ago, and the literature on the subject shows that there has been an entire change by the leading surgeons of this country and of Europe in the method and technic of gastroenterostomy during that time. In this country, until about one year ago, most surgeons were either making the anterior anastomosis with an entero-anastomosis between the afferent and efferent limbs of the loop, or a posterior retrocolic anastomosis with a loop, and also an entero-anastomosis, frequently with obstruction or division of the proximal end of the jejunum, or with obstruction or division of the pylorus. Now, no surgeon would be considered modern in his methods, who did not as an operation of election eliminate the loop and the entero-anastomosis. Dr. Wathen never believed in or practiced any other method, claiming that the numerous immediate and ultimate bad results were all caused by a faulty technic. In the practice of Moynihan and Robson it was first noted that these complications did not follow the operation when the anastomosis was made posterior near the duodenojejunal junction to the lowest part of the stomach.

Dr. Charles G. Stockton, Buffalo, N. Y., said that while there are cases in which there is hemorrhage and no ulcer, there are also cases with cachexia in which hemorrhage is profuse and repeated and in which no ulcer and no cancer is to be found, either at the operation or at the postmortem. That class of cases should be borne in mind as being a source of disappointment to the surgeon and to the internist.

Dr. J. M. Anders, Philadelphia, stated that the surgeons and postmortem records of large hospitals have taught the internist that many cases of both gastric and duodenal ulcer go unrecognized. This fact renders it clear that diagnostic methods must be improved. In this connection, a point of first importance is that the internist follow the individual case to the operating table, if surgical intervention is required, with a view to confirming or disapproving his previous opinion with reference to the question of diagnosis. This is a means of improving one's diagnostic powers, which has scarcely been appreciated to the extent it deserves. From the statements made by Hemmeter and others, he said, it is obvious that the profession should inform itself in certain directions; it needs to be enlightened on the relation of pain, vomiting and other symptoms to the particular site of the gastric ulcer; also on the effect of ulcer according to its site on the bodily weight, and finally, by the special location of an ulcer on the development and character of the complications and sequelæ. Until information on these points is forthcoming, the ability to recognize these conditions and discriminate them from other affections, which simulate them, must remain imperfect.

Dr. Anders heartily endorsed what was said with reference to the importance of periodic occult bleeding as a diagnostic symptom of gastric and duodenal ulcer, but called attention to the fact that this valuable feature is often overlooked for the reason that in chronic ulcer the stools are often passed into the modern water-closet, hence are never observed. It should be an invariable rule in cases of gastric and duodenal ulcer to employ a bed-pan or other vessel, and a systematic, routine examination of both the dejecta and vomitus should be carried out.

It must be admitted, he said, that there is a surgical treatment and also a clearly-defined medical treatment of gastric and duodenal ulcer, but he emphasized the fact that the combined medical and surgical treatment can not fail of giving the best results, and by that he means observation of cases by both physicians and surgeons. The majority of the cases first fall into the hands of the internist, who, he thought, is inclined to procrastinate, as a rule, in the matter of procuring surgical advice.

Dr. Frank Billings, Chicago, said that he was glad to hear Dr. Hemmeter say that the Roentgen ray will always reveal a gastric ulcer. That has not been his experience. The Roentgen ray, in his estimation, is an instrument more at fault in its interpretation than any other diagnostic aid in use. The instruments used and the ray itself are all right, but they are operated by individuals who do not know how to use them and who do not know how to interpret shadows. If he had to rely on the Roentgen ray to prove, finally, that a patient had an ulcer of the stomach, he fears he could not do it.

As to the use of orthoform as a differentiation between gastric ulcer and cholecystitis, he has found that orthoform does not always stop the pain of ulcer.

Concerning the treatment, Dr. Billings emphasized what Dr. McCaskey said, to study the individual case and treat it individually. There are two varieties of ulcer, the acute soft and the chronic indurated ulcer. Physicians all are of the opinion that the former may heal under rest, whereas the spontaneous healing of a chronic indurated ulcer is always in doubt. The physician who has such a patient in charge and attempts to cure by the use of medical treatment for six months, must test results of the treatment by constant attention to all the symptoms recognized as ulcer. The motility of the stomach, the presence of pain and the presence of occult blood must be considered. The continued loss of blood in the stool goes on many times in cases that are under the rest cure, and such patients have anemia and continued loss of weight in spite of all attempts at rectal or other forms of feeding. This, in his opinion, is one of the chief reasons why such people are surgical patients. In other words, chronic indurated ulcer of the stomach is a surgical disease. That does not mean that it is going to be a cutting treatment. It is a mechanical treatment, and if the rest treatment can heal these patients it should be done, but it must be proven that the ulcer is healed. His experience has been that a majority are not healed. They are simply latent and usually are finally referred to the surgeon.

As to the end results of surgical treatment. The last word has not yet been said, and it means that the physicians and surgeons are not to quarrel over this matter. They must work together. The surgeons will let the internist have the opportunity to examine and to attempt to cure these patients in any way at his command, but failing to accomplish this, the surgeon shall have the patient. The surgeon should keep a record for several years, so that in five years we may have valuable data.

Dr. Alexander Lambert, New York, said the question that seems to be the most disputed is whether the patient should have water and ice during the rest treatment. What he said was that they may have it. Dr. Black, he thinks, is perfectly right when he says that some patients will do better without it because they are nauseated by water or ice. But it is impossible to lay down any hard and fast rule in that regard. These patients must be treated as individuals and not as a class. Make rules for each patient and not for all cases of gastric ulcer. The importance of absolute peristaltic rest was, he thinks, overestimated. The stomach should have complete rest from digestion and the mere giving of rectal enemata will not seriously disturb that rest. Absolute starvation may be wise in some patients, but it is certainly very unwise to take a half-starved patient, one who is going to pieces from malnutrition, anemia and starvation, and try to help him further by starving him for a week. In some cases it may be wise, while in others it is absolutely contraindicated.

Dr. William L. Rodman, Philadelphia, said that he believes that medical treatment should be carried out for four weeks and that then, if not successful, it should be followed by surgery. Chronic ulcer rarely is cured by medical means. It seems to be a surgical condition, just as acute ulcer is strictly a medical condition. He was very much gratified that practically all the essayists were agreed that the direct method is preferable in the treatment of hemorrhage, where it is practicable. Gastroenterostomy is a makeshift. It will not arrest hemorrhage from a vessel of any considerable size, but only a capillary leak, and in the majority of instances the hemorrhage is from a vessel of importance. He believes that this is a further argument for radical measures. If, as Dr. Hemmeter said, it is possible with the bismuth test and the *x*-ray to diagnose the site of ulcers, surgeons certainly will be able to excise these ulcers better than they can at the present time and with far better results. The trend is increasingly toward excision.

Dr. W. J. Mayo, Rochester, Minn., said that Dr. Munro, in calling this "no-loop" gastroenterostomy method the "Mayo operation," is doing them too much honor. There are really but two men who can claim any great amount of credit, Woelfler and von Hacker. All operations devised since their time have been merely modifications made to meet certain conditions. As to the operation which the Drs. Mayo have advocated, the only claim that they have in the operation, said he, is that they have gathered up from different men certain points and ideas that seemed good, assembled them as a whole, tied a string around them, and all they own is the string.

Surgery, he said, has made mistakes in connection with stomach operations, and when these are all summed up, it is the non-indurated mucous ulcer that has failed to obtain surgical relief and in many of these cases the diagnosis is still in doubt as the ulcer was not demonstrated. When the surgeon opens up the abdomen and fails to find what he expected, a gastric or duodenal ulcer, that is, when he can not demonstrate the ulcer and can not show that there are mechanical conditions present, he is getting on dangerous ground. He may have one of the cases that will be a discredit to surgery.

Differential diagnosis between gastric and duodenal ulcer is immaterial to the patient; he does not come to the surgeon filled with pride that he has a gastric ulcer, but he wants relief, and he can be surgically relieved as easily from the one condition as he can from the other.

Dr. Mayo endorsed everything Dr. Billings said. These cases are medicinally relieved and temporarily benefited, but are not often cured. It is up to the surgeon to show whether he can do better than can the medical man. So far as the indurated and calloused ulcers are concerned, they are surgical conditions. Dr. Mayo facetiously put it this way. When he has been asked when he considered that a gastric ulcer should be operated on, he has said not until it has had nine medical cures. These cases relapse. The patient gets a rest cure and is better for a few months. The trouble returns and he goes to some other physician, until, finally, he gets so that he starves himself, because, after all, it is the starvation that relieves, unless the ulcer is dealt with radically.

It is the same old question that came up in regard to gallstones and appendicitis; each attack had a medical cure, so that one case might mean ten or fifteen such cures. These cases do relapse and the majority of the patients will be treated surgically, if we can demonstrate to fair-minded men that we can get better and more permanent results than can the internists.

Clinical Notes

A CASE OF PURPURA HEMORRHAGICA.

LOUIS A. LEVISON, M.D.
TOLEDO, OHIO.

Patient.—A white woman, aged 55, was admitted to the Lucas County Hospital, Toledo, March 26, 1906, complaining of weakness and expectoration of blood.

Family History.—The woman's parents died of "paralysis," aged 65 and 64, respectively. One sister died of typhoid fever. There was absolutely no tendency to bleeding in any member of the family, either immediate or collateral. The patient had five children, one of whom died in infancy. The other four children are alive, and with the exception of a low order of mentality in one son, show nothing of interest.

Personal History.—The climacteric was passed at the age of 43, and neither then nor at her confinements was bleeding excessive. Her past life has been free from pathologic incidents, and with the exception of measles, "muscular rheumatism" and what she calls "eczema," there are no diseases to be recorded. The woman had once or twice complained of night-sweats; she had no other symptoms of tuberculosis. She would lie in bed too weak to walk; one attempt at walking was followed by collapse. She almost continuously expectorated a thin bloody sputum which oozed from the gums, palate, pharynx and tongue. Epistaxis recurred at varying intervals, lasting from a few minutes to three or four hours.

Examination.—Temperature was normal; pulse varied from 62 to 98; respirations were 20. The "eczema" had left rather extensive scars over the flexor surfaces of both forearms and the left supraclavicular and infraclavicular fossæ. Syphilis was denied, and with the possible exception of these scars, there were no evidences of this disease. Nutrition was fair, and, despite the persistent hemorrhages, there was no great loss of weight. The face was very pale and the lips anemic. Lips, tongue, gums and palate were covered with a dark brown stain, consisting of dried blood. The tonsils were not enlarged. When bleeding from the mouth was free, small blebs containing blood could often be observed on the hard palate.

These varied from 5 to 10 mm. in diameter. The nostrils at times were also covered with dried blood. The pupils were equal and responded to both reflexes. The glands of the body were not perceptibly enlarged. The skin was soft, moist and over the flexor surfaces of each forearm and the left clavicular were depressions, extensively scarred. These scars, particularly over the arms, had a peculiar network-like appearance. The thorax was of fair size, symmetrical with fair expansion. Palpation, percussion and auscultation showed normal lung findings. The apex impulse of the heart was ill-defined in the fifth interspace within the nipple line. The heart was normal in size. At the apex was a very soft, systolic murmur, not transmitted to the left side or back. The abdomen was apparently normal. There was no sensitiveness to pressure; the liver and spleen were not palpable and showed no increase or decrease in percussion boundaries. The ankles and feet were not edematous throughout the course of the disease, but became slightly so after the patient left the hospital. The genitalia and rectum were negative.

Hemorrhagic Eruption: Scattered over face, trunk, arms and legs were innumerable fine petechiæ, varying in size from 1 to 5 mm. By far the greatest number were very small, pinhead spots. They were most thickly placed over the extensor surfaces of the legs, between the knees and ankles. Here it was impossible to touch a spot with the end of the finger, where the skin was clear. Over the remaining parts of the body, the back, chest, face, arms, hand, etc., the spots were more discrete and also larger. The spots partially disappeared at times, and about May 1 the body was fairly clean; although at the places where the lesions were thickest, the skin had a greenish-yellow tinge from the decomposed blood. Slight bruises, incidentally sustained, were marked by bloody extravasations out of all proportion to the injury. None of the petechiæ disappeared on pressure.

Blood examinations were interesting. Table 1 shows the number of red and white cells and the hemoglobin per cent. (Dare).

Table 1.

Date.		Erythrocytes.	Leucocytes.	Hmg. %.
March	26	4,720,000	5,400	55
April	16	2,816,000	3,600	..
April	19	3,176,000	....	..
April	25	1,336,000	2.600	35
April	28	2,528,000	3,000	30

June	19	5,152,000	3,200	85

Table 2.—Differential Count.

Date.		Polymorphonuclears.	Lymphocytes.	Mononuclears.	Mast Cells.	Eosinophiles.
April	25	63	31.5	5	0	0
May	1	59.5	26.5	13	1	0
May	5	45	43	9	1	0
May	9	50	41	9	1	0
May	17	46	30	22	3	0
June	19	60	30	9	1	0

In making a differential count, both small and large lymphocytes are included under lymphocytes and the transitional cells are counted as mononuclears. The important alterations in these counts have been the high proportion of lymphocytes and the absence of eosinophiles.

In examining smears, while not making regular counts, I did see one and possibly two eosinophiles. This small number out of many thousands of white cells observed is of distinct interest. The coagulation time of the blood was delayed at first to ten minutes, but this period was shortened during the course of the disease. Red blood cells did not show many changes. Aside from the diminution in hemoglobin, the cells were not altered. Neither poikilocytosis, polychromasia nor basic stippling was noted. Parasites were absent.

Blood Cultures: Cultures were made in bouillon, glucose agar, nutrient agar and blood serum, but all these remained sterile. Inoculations of blood from veins of elbow into guinea-pigs were negative. The stools contained no blood.

Urine Examination: The urine was slightly turbid, light yellow, specific gravity 1020, acid. The twenty-four-hour amount varied from 1,000 c.c. to 3,040 c.c. The last examination showed the merest trace of serum-albumin: no serum-globulin or albumoses; glucose was absent. Microscopic examination showed a few red blood cells; no casts; calcium oxalate crystals were found in abundance.

Treatment.—On admission, the patient was given calcium chlorid internally, in gram doses four times daily. This was discontinued after three or four days, on the theory that it decreases the coagulability of the blood, if given for longer periods of time. Gelatin was given freely during the patient's entire stay in the hospital. The mucous membranes were painted with adrenalin chlorid during the hemorrhagic attacks. Iron and arsenic were given in the form of Blaud's mass and Fowler's solution, respectively.

Result.—Condition of the patient very slowly and gradually improved and she was able to go to her home ten weeks after admission. At present, the hemorrhagic attacks have ceased, but a considerable number of fine petechiæ remain.

REMARKS.

Purpura hemorrhagica has assumed much interest of late in connection with the bacterial investigations of many workers in this field. Letzerich was able to isolate an organism from the blood of a female patient, which produced purpura in rabbits. Other investigators have found bacilli or streptococci. The findings of various writers on this subject have been too divergent for us to consider the etiologic factor of purpura hemorrhagica as settled. In connection with the bacterial origin of this disease the low percentage of eosinophiles in this case is of interest. Simon has pointed out the relative decrease of eosinophiles in the infections, and this finding in the case is for that reason worthy of record as a possible link in the chain of evidence which tries to prove purpura an infectious disease.

Simon believes that a hypo-eosinophilia associated with an increase of the polynuclear neutrophilic elements is one of the "most subtle means of diagnosing certain bacterial infections," and cites a list of infections, including appendicitis, pneumonia, empyema, variously-situated abscesses, peritonitis, etc., in which this finding is present. If further observation should bear out the constancy of this septic factor of Simon its importance as a diagnostic sign would be unquestioned.

POISONING FROM OIL OF TANSY.

E. GARD EDWARDS, M.D.
LA JUNTA, COLO.

A case cited in The Journal, Aug. 11, 1906, prompts me to add to the literature the following case:

Patient.—C. H. J., aged 25, married, a large strong woman.

History.—I found patient in a convulsion that had every appearance of epilepsy and a history of having had three such attacks within a short time. The symptoms were almost identical with those described by Dr. Whitehill in the article referred to above. Respirations were rapid, pulse 124 and forcible; pupils dilated and without reaction, mouth bleeding, patient absolutely unconscious. There was a faint odor from the breath that reminded one of some pungent oil.

Treatment.—Acting on general principles, I gave 1/10 gr. of apomorphia. In spite of her benumbed condition, this produced copious vomiting, which was aided by filling her stomach, by a tube, with large quantities of warm salt water. One slight convulsion appeared after the administration of the emetic, and in forty minutes the patient was beginning to show signs of consciousness. At this time the respirations were 20, pulse 108, temperature 97. A hypodermic of strychnin, 1/30 gr., was given, and rest enjoined. Six hours later conditions were normal except temperature was subnormal.

Result.—The next day the patient was apparently as well as ever, and confessed to having taken 2 drams of oil of tansy about an hour before I was called, because of being overdue four days as to her periods, which had appeared some twelve hours after taking the medicine.

New and Non-Official Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NON-OFFICIAL REMEDIES." THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 859.)

ARISTOCHIN.

ARISTOQUIN. DIQUININE CARBONIC ESTER. CARBONYL QUININE.

Aristochin, $CO(C_{20}H_{23}N_2O_2)_2 = C_{41}H_{46}N_4O_5$, is the neutral carbonic ester of quinine.

It is prepared according to the patents by acting on quinine dissolved in pyridin or chloroform with carbonyl chloride or by heating together quinine and phenol carbonate in the proportion of one molecule of the latter to two molecules of the former.

It forms a white, absolutely tasteless powder, melting at 189° C. (372.2° F.) insoluble in water, difficultly soluble in alcohol, more soluble in warm alcohol and chloroform, very sparingly soluble in ether. It is capable of combining with one and two molecules of hydrochloric acid forming soluble salts. It is gradually decomposed by acids with liberation of quinine, thus acquiring a bitter taste; hence it is incompatible with acids.

It should be free from bitter taste. As it is decomposed by acids and alkalies with the formation of quinine, it should respond to tests for quinine after such treatment.

Actions and Uses.—The same as those of quinine, but, since it is only slowly acted on by acids, it is said not to produce disturbance of the stomach and to be notably free from tendency to production of cinchonism.

Dosage.—The same as that of quinine, in powder, mixed with milk sugar, dry on the tongue or suspended in liquids.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). German patents No. 105,666, 134,307 and 137,308. U. S. patent No. 625,075.

ARISTOL.

A name applied to Thymolis Iodidum, U. S. P.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. trademark No. 17,393.

ASPIRIN.

ACETYLSALICYLIC ACID.

Aspirin, $C_6H_4.O(CH_3CO).COOH$, 1:2 $= C_9H_8O_4$, is the acetyl derivative of salicylic acid.

It is prepared by the prolonged heating of 50 parts of salicylic acid and 75 parts of acetic anhydride at about 150° C. (302° F.) under a reflux condenser, and subsequent purification, by recrystallization from chloroform.

It forms small, colorless, crystalline needles, melting at 135° C. (275° F.), odorless and having an acidulous taste. It is soluble in 100 parts of water and freely soluble in alcohol or ether. It is readily split up on boiling with water or with alkalies with the production of acetic acid and salicylic acid or a salicylate.

It forms clear, colorless solutions, which do not develop a violet color on the addition of ferric chloride unless previously hydrolysed by boiling with sodium hydroxide. It gives no reaction with silver nitrate, and should leave no residue when heated on platinum foil.

It is incompatible with heat, moisture, alkalies, their carbonates and bicarbonates. It keeps well when properly protected.

Actions and Uses.—It acts like salicylic acid, over which it possesses the advantage of producing less of the undesired local and systemic side effects, on account of the slow liberation of the salicylic acid. It passes the stomach unchanged, the decomposition beginning in the intestine.

Dosage.—0.3 to 1 Gm. (5 to 15 grains) in capsules or wafers, or dissolved in sweetened water or dry on the tongue, followed by a swallow of water. The powder should be dispensed in wax paper.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. patent No. 644,077. U. S. trademark No. 32,805.

BENZOSOL,

GUAIACOL BENZOATE. BENZOYL-GUAIACOL.

Benzosol, $C_6H_4(OCH_3)(C_6H_5COO){=}C_{14}H_{12}O_3$, is a crystalline compound of guaiacol in which the hydrogen of the hydroxyl is replaced by benzoyl.

It is prepared by warming the potassium salt of guaiacol with benzoyl chloride and crystallizing the product from hot alcohol.

It forms colorless, minute crystals which melt at 59° to 61° C. (138.2° to 141.8° F.); they are odorless and tasteless or nearly so. It is practically insoluble in water, sparingly soluble in ether, but readily soluble in hot alcohol. It contains 54 per cent. of guaiacol.

It forms with sulphuric acid a permanent yellow coloration which on the addition of acetone assumes a characteristic, brilliant cherry red color, distinguishing it from salol, which gives a yellow color. Ferric chloride produces in the benzosol sulphuric acid mixture a violet color, changing to green and blue, and, on the further addition of nitric acid, to orange and green, or of potassium nitrite to green, violet and yellow. When heated (saponified) with alcoholic potash, the odor of guaiacol is developed.

It is incompatible with the alkalies, which split up benzosol into guaiacol and benzoic acid.

Actions and Uses.—Benzosol is decomposed slowly in the intestinal tract into guaiacol and benzoic acid which exert their proper actions. The liberated constituents are absorbed and excreted in the urine. It is not irritating.

Its uses are analogous to those of creosote and of benzoic acid. It is recommended in incipient pulmonary tuberculosis, as an intestinal antiseptic in fermentation. diarrhea, typhoid fever, diabetes mellitus and as a urinary disinfectant in cystitis, etc.

Dosage.—0.2 to 0.6 Gm. (3 to 10 grains), in powder, capsule, pill, or suspended in liquids or as an emulsion.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M. (Victor Koechl & Co., New York). U. S. patent No. 453,035.

BETA-EUCAINE HYDROCHLORIDE.

EUCAINE HYDROCHLORIDE-β. BETA-EUCAINE.

Beta-eucaine hydrochloride, $C_5H_7N(CH_3)_3(C_6H_5COO).HCl$, is the hydrochloride of 2,6,6-trimethyl-4-benzoyl-hydroxypiperidine.

It is prepared by treating diacetonamine with paraldehyde, reducing the product with metallic sodium, benzoylating the vinyldiacetonalkamine so produced by treatment with benzoylchloride, neutralizing the resulting benzoylvinyldiacetonalkamine with hydrochloric acid and crystallizing.

It forms a white crystalline powder, soluble in 20 parts of water at the ordinary temperature, but more soluble in warm water, soluble in 14 parts of alcohol, producing neutral solutions which can be sterilized by boiling without change. The aqueous solutions yield ether soluble precipitates of the free base on addition of alkali hydroxides or carbonates.

The saturated aqueous solution gives no precipitate with mercuric chloride, which distinguishes it from the corresponding alpha-eucaine salt. It gives no color reactions with sulphuric or nitric acid, but yields a yellow precipitate with chromic acid. orange yellow with bismuth-potassium iodide, lemon yellow with picric acid, and a white precipitate with phosphomolybdic acid. It is incompatible with alkalies and their carbonates.

Actions and Uses.—Beta-eucaine hydrochloride is a local anesthetic like cocaine, but weaker and devoid of the stimulating properties of the latter. It does not dilate the pupil, nor does it contract the blood vessels as does cocaine. It has the advantage of stability even on prolonged boiling. It may be used in all cases in which cocaine is indicated as a *local anesthetic, especially* in ophthalmology.

Dosage.—It may be applied in a 2 to 3 per cent. solution to the eye, 5 to 10 per cent. for nose and throat and 5 to 10 per cent. for ointment for hemorrhoids.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin (Schering and Glatz, New York). U. S. patent No. 657,880. German patent No. 97,672.

BETA-NAPHTHOL BENZOATE.

BENZONAPHTHOL. BENZOYL-β-NAPHTHOL. NAPHTHOLIS BENZOAS.

Beta-naphthol benzoate, $C_6H_5.COO.C_{10}H_7 = C_{17}H_{12}O_2$, is the benzoic ester of β-naphthol.

It is obtained by heating b-naphthol and benzoyl chloride together at 170° C. (338° F.), extracting the product with alcohol, and crystallizing.

It forms colorless needles, or a white crystalline powder, colorless and tasteless, melting at 110° C. (230° F.). It is almost insoluble in water, but readily soluble in alcohol and in ether; it is also soluble in chloroform, in glycerin and in olive oil.

Benzonaphthol is decomposed by heating with caustic alkalies into naphthol and a benzoate which will then give their characteristic reactions.

To test benzonaphthol for the presence of b-naphthol it should be shaken several times with dilute solution of sodium hydroxide (1:10) and immediately filtered. If beta-naphthol is present in considerable amount it will separate as a turbidity or precipitate after acidifying with dilute sulphuric acid. If the amount of betanaphthol is small no precipitate appears, but the alkaline solution shows a bluish fluorescence and if it is boiled with chloroform, a green color is produced.

A solution of benzonaphthol should not give a violet color with chloride of lime or solution of iodine and alkali.

It is incompatible with antipyrine, camphor, phenol, ferric chloride, menthol, potassium permanganate, or urethane.

Actions and Uses.—Beta-naphthol benzoate is split up into its constituents on reaching the intestinal tract and acts as an antiseptic. It is said to be diuretic. It is used internally as an intestinal antiseptic in diarrhea and typhoid fever. Externally it has been recommended as a parasiticide in the form of 3 to 10 per cent. ointment, and has been used in psoriasis, eczema, scabies, etc.

Dosage.—0.2 to 0.5 Gm. (3 to 8 grains); maximum dose, single, 1 Gm. (15 grains), daily 4 Gm. (60 grains).

Manufactured by Fabrik von Heyden, Radebeul near Dresden (Merck & Co., New York). It is not patented nor trademarked.

BETOL.

NAPHTHALOL. NAPHTHOL-SALOL. SALINAPHTHOL.

Betol, $C_6H_4.OH.COO(C_{10}H_7) = C_{17}H_{12}O_3$, is the salicylic ester of β-naphthol.

It is obtained by heating b-naphthol-sodium and sodium salicylate with phosphorus oxychloride at 120° to 130° C. (248° to 266° F.).

It is a white, shining, crystalline powder, odorless and tasteless, melting at 95° C. (203° F.). It is insoluble in cold or hot water or glycerin, difficultly soluble in cold alcohol or turpentine, easily soluble in boiling alcohol, in ether, in benzene, and in warm linseed oil. In the cold it is not changed by acids or alkalies of moderate concentration. When heated with alkalies, it is decomposed into its constituents, which, if the solution is acidulated, will crystallize.

It is distinguished from salol by its higher melting point and by the production of a brownish green color, when a trace of nitric acid is added to its yellow colored solution in pure sulphuric acid. It burns on platinum foil leaving no residue (absence of fixed mineral impurities).

If 1 Gm. of betol is shaken with 30 Cc. of boiling water and filtered through a moistened filter, the filtrate should not have an acid reaction, (absence of salicylic, hydrochloric or phosphoric acid) nor should it after cooling show a crystalline deposit (salicylic acid or b-naphthol) and should not become turbid on the addition of silver nitrate (chlorides or phosphates) or barium nitrate (absence of sulphates) nor should it give a violet color with solution of ferric chloride.

Actions and Uses.—Betol is not affected in the stomach, but is split up in its original components when it reaches the intestinal tract by the pancreatic juice and intestinal secretions. It is believed to act as an intestinal antiseptic and, being excreted in the urine, to act in a similar way in the bladder.

It has the antirheumatic properties of salicylic acid. It is recommended for intestinal fermentations, catarrh of the bladder, particularly in gonorrheal cystitis, for rheumatism, etc.

Dosage.—0.3 to 0.5 Gm. (4 to 8 grains) in cachets, milk or emulsion.

Manufactured by The Heyden Chemical Works, New York. U. S trademark.

BISMAL.

BISMUTH METHYLEN-DIGALLATE.

Bismal, $4(C_{15}H_{12}O_{10}).3Bi(OH)_3 = Bi_3C_{60}H_{57}O_{40}$, is a compound of bismuth hydroxide and methylendigallic acid.

It is obtained by digesting 4 molecules of methylendigallic acid with three molecules of bismuth hydroxide in water.

It is a voluminous gray-brown powder, insoluble in water or gastric juice, but soluble in alkalies, forming yellowish red solutions.

Actions and Uses.—Bismal is an astringent and is recommended for the treatment of chronic diarrhea.

Dosage.—0.12 to 0.3 Gm. (2 to 5 grains) in cachets or powder.

Manufactured by E. Merck, Darmstadt (Merck & Co., New York). U. S. patent No. 605,240, German patent No. 87,099 (dropped in 1899).

BOROCHLORETONE.

A mixture of 1 part of chloretone (chlorbutanol) with three parts of boric acid.

Actions and Uses.—An antiseptic and anesthetic, used externally as a surgical dressing powder.

Prepared by Parke, Davis & Co., Detroit Mich. U. S. trademark.

BROMETONE.

TRIBROM-TERTIARY-BUTYLALCOHOL. ACETONE-BROMOFORM.

Brometone is 1,1,1-tribrom-2-methyl-propan-2-ol, $CBr_3.C(OH)(CH_3).CH_3 = C_4H_7OBr_3$, produced by the reaction of acetone on bromoform.

Made by the action of caustic alkalies on a mixture of bromo form and acetone.

Occurs in fine white, prismatic crystals which possess a camphoraceous odor and taste. It is slightly soluble in water, soluble in alcohol, ether, benzin and most organic solvents. It melts at about 167° C. (332.6° F.) and volatilizes on exposure to air.

Actions and Uses.—Brometone is claimed to have the sedative action of the bromides without the disadvantage of producing bromism. In doses of 0.3 Gm. (5 grains) four or five times a day, in adults, it is claimed to cause no unpleasant results and to produce no disturbance of the digestive organs, and to have no appreciable effect on the secretions. Its action is prompt and its effect is manifest for several hours. In doses exceeding 1.6 Gm. (25 grains) daily it may produce dizziness, vertigo, anorexia, and mental hebetude, all of which symptoms disappear on discontinuance of its use. Therapeutically it has been recommended in mild conditions of excitation and insomnia, in so-called narcotic abstinence, in hysteria and in nervous affections generally. It relieves some forms of cough and is said to produce amelioration in about 60 per cent. of cases of epilepsy. It has been used to relieve dizziness due to labyrinthine disturbances.

Dosage.—The dose is 0.3 Gm. (five grains), to be repeated two or three times during twenty-four hours.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

(To be continued.)

Radium in Trachoma.—Radium has been successfully applied by Kardo-Sisoyeff in 38 cases of trachoma, as he reports in *Russky Vrach.*, No. 20, 1906. The exposures were made every 2 or 3 days by means of a small tube containing about 10 mg. of radium. The tube was not pressed on the mucous membrane of the everted lids, but merely applied lightly and moved from place to place. The duration of each exposure was one minute. The benefit of the treatment was apparent as early as the second or third day, the granulations having become smaller, with very slight congestion. All forms of granulated conjunctivitis were treated, but the best results were obtained with papillary trachoma and diffuse infiltration. Especially in case of pannus the subjective symptoms were relieved by the second day, the lachrymation, photophobia, and spasmodic contractions of the lids.

SATURDAY, SEPTEMBER 22, 1906.

DISINFECTION.

Dr. Chapin's paper on disinfection[1] is of the kind that may do much good because it is likely to lead physicians to review critically their own ideas, convictions and practices anent disinfection. Judging from some of the remarks in the discussion of the paper, the word disinfection, as used by Dr. Chapin, seems liable to be interpreted wrongly. It is absolutely necessary in discussing this paper to bear in mind that the disinfection dealt with by its author is that "which is commonly carried out by health officials after death or recovery from contagious diseases." It is the routine practice of this sort of disinfection that Dr. Chapin attacks. As to cleanliness and other disinfective measures during the course of a contagious disease, Dr. Chapin appears to hold only the most orthodox views; and he emphasizes the far greater value of continuous cleansing, in the real meaning of the word, as compared with the perfunctory terminal disinfection, in limiting the spread of communicable diseases.

It can not well be denied that if proper isolation and real cleanliness be maintained from the beginning to the end of an infectious disease, counting the end as the period when there is adequate ground to believe that neither the patient nor his attendants and others with whom he has come in close contact during his illness any longer harbor the infecting agent, then there will be no call for the elaborate official terminal disinfection now prescribed and more or less commonly practiced. Clearly this ideal condition of things is not as yet generally realized or realizable. It is, however, the objective point of our efforts to minimize the spread of infection by the patient, and when this point is actually reached in a given case terminal disinfection should be omitted because unnecessary. There is, then, room for intelligent discrimination in terminal disinfection.

Certainly Dr. Chapin is correct, also, in his interpretation of the evidence of the relative importance of living beings and dead objects as carriers of infection. To-day there is no escape from the conclusion that the most important sources of infection in the diseases now in mind are the sick or convalescent patient, whether the disease is typical or atypical, and the so-called healthy "carrier." These sources may be ambulatory; in them the infective agents may multiply and persist; the most that contaminated dead objects ordinarily subjected to disinfection can do is to harbor for a variable time the causative agents which now only rarely find suitable conditions for multiplication. Hence terminal disinfection, even when effective, in reality possesses a relatively small power to limit infection, for the simple reason that fomites, after all, play a subsidiary rôle in the spread of infection. This being the case, it is a mistaken policy to rely on terminal disinfection to the extent that adequate and proper isolation and continuous cleanliness and the special precautions indicated in each particular disease become neglected. And this is the necessary result of blind, indiscriminating reliance on so-called disinfection as practiced by virtue of custom and dogma, and the real disinfectiveness of much of which may well be questioned.

Such questions as the real value of terminal disinfection are settled definitely by actual experimentation. Statistical studies are essential. It is desirable that the subject receive more attention from the investigative point of view than heretofore. Mere affirmation of a fact, e. g., the efficiency of disinfection, does not create that fact. There is already actual evidence at hand that tends to create doubt of the value of disinfection. Thus Dr. Chapin states that in Providence there was a recurrence in only 1.55 per cent. of 258 cases in which the warning card was removed without official disinfection—a somewhat better showing than in the control instances. In the *Semaine Médicale*[2] it is pointed out editorially that in Paris obligatory disinfection has been practiced systematically under favorable conditions for about fourteen years, but during the decennium 1895-04 there was no fall in the morbidity of scarlet fever, diphtheria and typhoid fever, while that of variola increased. There were some oscillations in the mortality, but no decided fall. These facts are interpreted as proof of the inefficiency of disinfection as carried out in France. We need further observations of this character.

While the value of terminal disinfection, for good reasons, is being questioned, the possible benefits of effective disinfection must not be withheld in the many instances where circumstances appear to indicate disinfective measures. This is true particularly in the case of tuberculosis in which precautionary measures and cleanliness have been neglected. In certain other diseases, e. g., typhoid fever, diphtheria, Dr. Chapin very properly places as a prerequisite a reasonable certainty that all the members of the household are free from infection. The burden of establishing this freedom from infection in most cases falls on our public health officials.

In determining their attitude toward the questions here discussed physicians should bear in mind that as our knowledge of the infectious diseases grows, especially as regards the sources of infection, the methods of best combating communicable diseases necessarily require readjustment. This does not involve any weakening of "the germ theory" of infectious diseases. On the contrary a strengthening. Further, that at present the most effective preventive methods known are, speaking broadly, adequate isolation of the patient, continuous cleansing, i. e., disinfection, during the course of the attack, due recognition of the important and often too much neglected healthy carriers, and in certain diseases prophylactic immunization (vaccination, diphtheria antitoxin).

[2] July 25, 1906.

COLONIES FOR EPILEPTICS.

According to a careful estimate, says *Coöperation,* the organ of the Chicago Bureau of Charities, one in every five hundred of the population is an epileptic, and it, therefore, argues the importance of establishing public institutions for the care of these unfortunates. They are, it says, a burden to their friends and a menace to the welfare of others with whom they are associated, and yet they are not properly suited for the public institutions to which many of them are sent.

To a very large extent, this is the truth, but it is not exactly correct to infer that all cases need care in the same class of institutions, or even in any institution at all. The total of epileptics must include an appreciable number of individuals whose epilepsy is a comparatively slight disability and who are capable of maintaining themselves under the ordinary conditions in society. There are some, as physicians can testify, who, while suffering from occasional epileptic attacks, have their working power and social efficiency very little, if at all, impaired. There is another small minority of epileptics who require close restraint on account of their mental condition, and this class is much less than it would appear to be from the mistaken methods of their management. Many of the so-called dangerous epileptics are such only because of bad surroundings, ill treatment and probably also, in some cases, ill-advised medication. The fact that the use of the bromids can cause dangerous maniacal conditions was very early observed in the medical history of the drug, but has been too little appreciated, even up to very recent years.

A very large class of the epileptics, and probably the great majority, are perfectly suitable cases for an epileptic colony, in which they can be made not only happier and better in every way, but largely self-supporting. Perhaps it is not too much to claim that nine-tenths of those who are not practically disabled by their disease could be thus cared for. Under judicious management it is safe to say that the public epileptic colony could be the least expensive or burdensome to the taxpayer of any of the public charities. While economy should not be the first consideration, the nearest to self-support that is compatible with proper humane and scientific treatment should at least be the ideal in such institutions. There is no member of society that is more misunderstood by the general public than the so-called dangerous epileptic. A few are really dangerous and require restraint; the great majority of even the severe cases are perfectly manageable under proper surroundings by judicious moral and medical treatment. It would be impossible probably to remove every epileptic to such a colony, but for the great mass of those who are under public and private care it would be a blessing, and also a saving of public and private expenditure.

Epilepsy is not absolutely an incurable disease, even in such cases as are sent to the public institutions, there may be some capable of cure, and the curative treatment might well be an important object of the institution even if the results are not very great. The careful study of the disease will undoubtedly bring out many valuable facts and widen the scope of the curative function of the institution. At least this is a thing to be worked for, though the prospects of extensive results may not be the best. What has already been done abroad and in this country shows the possibilities for good of such colony treatment of the epileptic.

MILK AND ALCOHOL IN HOSPITALS.

Some very interesting data with regard to the comparative consumption of milk and alcohol in the London hospitals during the past forty years was the subject of an important communication from Sir Victor Horsley, the distinguished London surgeon, at the recent meeting of the British Medical Association at Toronto. These data are not likely to reach physicians through the ordinary channels because they were announced at the temperance luncheon instead of at the usual section meetings. According to Dr. Horsley the proportionate consumption of alcohol and of milk has been exactly reversed during the past forty years as the result of advance in medical knowledge with regard to the inefficiency of alcohol for the cure of disease. Forty years ago, at the beginning of the seventh decade of the nineteenth century, the expenditure for alcohol in the London hospitals was about $40,000 a year. The expenditure for milk during the same period was about $15,000. At the present time the annual expenditure for alcohol for medicinal purposes is about $15,000. The milk account on the other hand now runs up to over $40,000.

This represents very nearly the reversal of feeling in physicians' minds with regard to the relative value of these two fluids for the treatment of ailments of various kinds. It is true, as Sir Victor Horsley suggested, that the introduction of antisepsis and asepsis into hospital practice has accomplished not a little in doing away with the supposed necessity for stimulants. Forty years ago septic conditions were very common in the London hospitals and they were nearly always treated—as a sort of last resort—by large quantities of stimulants. Very few surgeons who recall those days consider that the stimulants did much good, but something had to be done, and the remedy at least gave a sense of well being to the patient that prevented most of the symptoms of discouragement in the face of surely advancing death.

Milk, however, has risen very much in the estimation of physicians during the past half century. Not a little prejudice existed, especially with regard to the consumption of large quantities of milk, and it was somehow thought, because of isolated unfavorable experiences, to be rather difficult of digestion by those who were in poor health. Now, however, it is recognized that observations of this kind were due to individual idiosyncrasies, and milk has come to be looked on as the most important element for conserving strength and renewing tissue loss that the physician has at his command.

It seems very probable that this difference of attitude with regard to both alcohol and milk will continue to be even more marked as the years go on. While here in America, perhaps, such a complete reversal of form has not taken place, this is partially due to the fact that American physicians were never as free in their use of alcohol for medicinal purposes as their British colleagues, while the movement that has emphasized the comparative inefficiency of alcohol for many symptoms for which it was supposed to be almost the supreme remedy began later in this country than in England.

THE LIFE INSURANCE EXAMINER AND THE AGENT.

We have referred to a number of improvements in life insurance examination work that ought to be secured. The attempt of an agent to use an examiner in trying to coerce an individual to make application for insurance is another abuse which is detrimental to the reputation of both company and agent; it is resented by the applicant and often subjects the examiner to insults. The examiner should never be asked to make an examination until the application has been made. When he is sent to call for an examination where the individual has made no agreement or appointment, the agent should be required to pay the usual fee, and for repeated offenses of this kind should be disciplined by the proper officials of the company. It saves time and annoyance to both the examiner and the applicant for the physician to make his own appointment by telephone or otherwise. The contention sometimes made that such a communication may give a half-persuaded applicant an opportunity to withdraw his application is a sad commentary on the current methods of life insurance soliciting.

This insane haste to rush the application to the home office, and to force a policy on an individual who has not been convinced that he desires it, is responsible for the fact that a more exhaustive and leisurely examination can not be made in doubtful cases. The use of the more refined methods of diagnosis, among them the examination of the blood, the estimation of the blood pressure, the use of the ophthalmoscope, and the more exhaustive study of the urine, both clinical and microscopic, in a twenty-four-hour specimen, would sometimes enable the examiner to discover defects or to eliminate the possibility of their existence, while without them his judgment of the risk must be uncertain. Of course, where such supplementary examinations are made, a reasonable fee should be added to the minimum fee of $5.00 for the regular examination.

A reform in some of these features of the life insurance business would conduce greatly to the comfort and efficiency of the medical examiner, would be to the advantage of the insurance company, and ultimately to that of the agents, who are in the main responsible for the existing conditions.

PRIVATE GAIN vs. PROFESSIONAL BENEFITS.

Last week we devoted considerable space to our esteemed contemporary, the New York *Medical Record*, and its attacks on the American Medical Association. Underlying the series of *Record* editorials was the insinuation that the American Medical Association, through its Journal, was accumulating money, and, further, that this money was being squandered or misappropriated, or something of the kind, by the trustees or by the officers of the Association, because—in the *Record's* opinion—a sufficiently detailed report of the affairs of the Association was not published to the world. This impression was conveyed in spite of the fact that every detail has been and is available at any time to those who are entitled to it. The *Record's* position as a critic in this matter will be appreciated when it is known that it does not publish and will not make known to any one even so much of its own affairs as its circulation. Every physician who contributes an article to the *Record* is interested in this particular information; he naturally wants to know something of the extent to which his article will be circulated if published in that periodical. Its circulation is also most important information for its advertising patrons, and is something that every advertiser has a right to know. The *Record* guards this information with the utmost care. It is conjectured, however, that its circulation is anywhere from 6,000 up—possibly the figure given is near the truth. It must be admitted, however, that if current reports are to be relied on, its circulation is constantly decreasing, and it might be embarrassing for William Wood & Co. to admit this publicly. But, be this as it may, what right has the *Record* to criticise the Association for the alleged withholding of minor details when it refuses to give to its patrons and supporters information of such fundamental and vital importance as its circulation?

Let us, however, consider another matter: We do not know what William Wood and Co.'s profits are from the *Record*, and it is not expected that a private firm will publish such information. Considering, however, that the *Record* gives little more than half as much reading matter as does the Association Journal, at the same subscription price, and that its advertising receipts from this source are large, it may be assumed that William Wood & Co. receive a fair profit from their paper, which is as it should be. In one of its editorials, the *Record* referred sarcastically and erroneously to a so-called surplus of a quarter of million dollars of the American Medical Association, not recognizing the difference between surplus and assets. In the commercial reports William Wood & Co., medical publishers, are rated at a pecuniary strength of from $300,000 to $500,000. Whence and from whom came this princely fortune? Since their business has been limited to publishing medical books and medical journals, it is fair to assume that it came from our profession. And what has William Wood & Co. done for the medical profession in return for this generous support which it has given them? Have they done anything? Nothing, absolutely nothing! Why should they! Since they are a commercial firm, what interest have they in our profession except what they can make out of it?

Now, what about the American Medical Association? Its income has been derived entirely from The Journal, which, for some years past, has made a fairly good profit. But these profits have been and are being used for the medical profession of the whole country, not necessarily for the individual members of the American Medical Association alone. From these profits the Association has been able to erect a building for its headquarters, thus realizing an ambition cherished by its members for many years; and has land to extend this building as the necessities of the future may require. It also has a reserve fund for future contingencies. For several years it has appropriated money for scientific research and for the development of organization and for better society work. To aid this work it is publishing a bimonthly bulletin, a periodical which is sent free to the presidents and secretaries of all the state and county societies of the country, to the councilors of the various state societies, and to others especially interested in building up county societies and making them more effective for good. Through its Council on Medical Education, it is working for higher standards and better conditions in medical education; and, through its Council on Pharmacy and Chemistry, it is endeavoring to check the dishonest practices of those who are offering to the medical profession fraudulent medicines and nostrums. For all this, and for other work of direct and indirect benefit to the medical profession as a whole, and to the public, the Association has been and is spending the money that it has received in profits from its Journal.

A year and a half ago the Association entered on a campaign to expose and to check the frauds and deceptions that had developed in the proprietary medicine business. It was known that the movement would be opposed by some of the journals whose existence depended on the support of those who would suffer from this campaign. It was not believed, however, that the *Medical Record* would be found among these, standing, as it claimed to do, for scientific medicine, and receiving, as it did and does, its support from those physicians who would naturally endorse this campaign. It was naturally to be supposed that William Wood & Co. would see the righteousness of the movement and that, even at a temporary sacrifice of some of its advertising receipts,[1] they would endorse and support it. But what happened? Did they have the *Record* endorse it? Did they see the hand-writing on the wall? No. Not only did the *Record* not endorse it, but, on the contrary, it opposed it in many ways, using sarcasm and ridicule because it had no arguments to offer.

When certain nostrums which were being exploited to and through our profession were shown to be frauds, did the *Record* tell its readers about it? No. On the contrary, it sold an extra amount of advertising space to the promoters of one of these frauds to hold up to ridicule and caricature The Journal and the Council on Pharmacy and Chemistry, and then refused[2] to publish a reply in the form of a statement of facts. When the Porto Rico Commission sent a letter[3] to the *Record* correcting misstatements that were being circulated regarding a well-known proprietary preparation, the communication was not published, presumably because it reflected on one of the *Record's* most prominent advertisers; this in spite of the fact that the letter contained information that every reader of the *Record* should have received.

Thus the *Record*, by deliberately opposing the work of the Council on Pharmacy and Chemistry, by wantonly attacking the American Medical Association, and by attempting to cause discord in its ranks, by refusing to aid in the campaign against frauds in "patent medicines" and impure foods, and by siding with its advertisers rather than with its readers, has shown itself to be an enemy to the profession and antagonistic to the best interests of both the profession and the public. We leave it to the members of the profession to draw their own conclusions regarding the value, and, especially, the sincerity of hostile criticism emanating from such a source.

In conclusion, we again suggest to William Wood & Co. that they think over this whole matter; that they consider whether it becomes a firm, which has been able to amass a fortune from the support given it by the medical profession, to allow its publication to oppose a movement endorsed by the best element in that profession—a movement inaugurated for the furtherance of honesty in the pharmaceutical business, and for the benefit of the profession and the public.

---

[1] Just as a sample of the advertising carried by the *Record*, we refer to a few now running in its advertising pages: Antikamnia, Ammonol, Phenalgin, Sal Codeia—Bell, Bromidia, Iodia, Neurilla, Eusoma, Papine, Echtol. Germiletum, Dioviburnia, Neurosine, Seng, Cactina Pillets, Tongaline, Echitone, Hagee's Cordial of Cod Liver Oil, Gray's Glycerine Tonic Comp., Vin Mariani, Kutnow's Powder, Uron, Syrup of Figs, Anasarcin, Robert-Hawley Lymph Comp., Micajah's Medicated Uterine Wafers, Hayden's Viburnum Comp., Zymoticine, etc.

[3] The Journal A. M. A., Oct. 7, 1905, p. 1099.

STANDARDIZATION OF SUPRARENAL PRODUCTS.

One of the most important additions to our therapeutic agents during recent years is the series of preparations from the suprarenal gland. While we do not yet know how widely these preparations may be used with satisfactory results, we do know that their value as therapeutic agents is such that they are depended on in many conditions, and that they should, therefore, be of uniform quality and character. The reports[1] which we published two weeks ago of the experimental work on these preparations show very plainly that the preparations on the market are of variable quality and character. This must not be. There is probably as much need for the standardization of these preparations as there is for the standardization of other organo-therapeutic products, such as diphtheria antitoxin, vaccine virus, etc. It is perfectly practicable to determine the strength of these suprarenal preparations with accuracy and to standardize them. It is presumed that the preliminary investigation made by Dr. Reid Hunt for the Hygienic Laboratory of the United States Public Health and Marine-Hospital Service was primarily to show the need of this standardization, and we understand that this department of the government is considering the advisability of undertaking a supervision of these preparations similar to that which is so effective for good in the case of some other products. The Division of Pharmacology of the Hygienic Laboratory is well equipped to carry out this work. We have no doubt that the manufacturers will welcome such supervision, since it is to their interest, as well as to that of the profession and of the public, that the preparations should have a standard for the guidance of those who make as well as for those who use them.

CATCHY NAMES AND THEIR DANGERS.

In our news columns this week will be noted a death in St. Luke's Hospital, Chicago, from the accidental use of a solution of atropin when urotropin had been ordered. This incident calls attention to the evil attendant on the prevalent manner of naming new remedies—proprietary, in nearly every instance. Is it to be wondered at that mistakes are made when we have to contend with the following similar names of preparations of widely different character and composition: Sanatogen, Sanitol, Sanitas, Sanoform, Sanoforme, Sanosal, Sanose and Sanosin? Then we have a variety of names that apply to the same article, as occurs in this particular instance which has caused a death. Hexamethylene tetramine is now an official preparation in the U. S. Pharmacopeia as Hexamethylenamine—an awkward word for physicians to get used to, but one that it seems will have to be adopted. This was first introduced as Urotropin, but now is on the market as Aminoform, Cystamine, Cystogen, Formin, Hexamin, Uristamine, Uritone, etc. Why not get rid of all these names and adopt the correct one—the official name? If the one who prescribed the urotropin at the St. Luke's Hospital had desired to use Schering & Glatz's preparation, it would have been an easy matter to have written "Hexamethylenamine (Schering)." In hospitals where young physicians are taking their first work in actual practice, which is the case in all hospitals having internes, would it not be worth while to set a good example by prescribing remedies under their official titles and not by perpetuating proprietary names?

Medical News

CALIFORNIA.

Polyclinic Opened.—The San Francisco Polyclinic, formerly located on Ellis Street, was reopened at 443 Filmore Street, September 11.

Exclude Trachoma Immigrants.—The quarantine officer at San Francisco has refused landing to 48 persons suffering with trachoma, 27 of whom were Japanese and 15 Hindus, who arrived on the *Siberia*, September 12.

New College Building.—The College of Physicians and Surgeons, San Francisco, has let the contract for the erection of a one-story frame building, as a temporary building for its uses, along the northwestern line of Fourteenth Street and Woodward Avenue, for $19,722.

Personal.—Dr. Coyle J. Tracy, Pasadena, has been appointed a member of the insanity commission in Los Angeles County. ——Dr. and Mrs. John J. Tully, Stockton, have returned after an extended tour of Europe.——Dr. Redmond W. Payne, San Francisco, left for New York, September 8, en route for Europe.

The Dead in the San Francisco Disaster.—The health department announces that 452 persons lost their lives as a result of the earthquake disaster, April 18. Of these, 266 were killed by falling walls, 177 perished in the fire, 7 were shot, and 2 died as a result of ptomain poisoning. Of the dead, 420 are believed to have been white, 18 Chinese and 4 Japanese.

Typhoid Fever.—It is reported that Pasadena is infected with typhoid fever. The disease is not epidemic but endemic, and is said to be directly traceable to the beaches, which in the present season are a veritable hotbed for typhoid germs. Families leave their homes in Pasadena for two or three weeks, living in tents or shacks on the beach, where they use any kind of water available without regard for its purity, and are surrounded by conditions which are very insanitary.

New Hospitals.—Dr. John L. White, superintendent of the Sacramento County Hospital, has been given permission to erect an open-air hospital for consumptives, to cost about $600.——The Southern Pacific Medical Department plans to erect two cottages and a one story building on the present hospital grounds in Sacramento, as the accommodations for patients do not equal the demands on the institution.——Work on the San José County Hospital, to be erected at a cost of $65,000, on the site of the old county building destroyed by the earthquake, will be initiated in October, and it is probable that the building will be ready for occupancy six months later.——The Wentworth Hospital has been incorporated in Sacramento with a capital stock of $50,000, by Dr. E. M. Wilder, Sacramento, and others.——A hospital is to be built at McCloud by the McCloud Lumber Company, which will cost $25,000.

COLORADO.

Italian Dispensary Opened.—An Italian dispensary has been opened at Palmer and West Thirty-fifth avenues, Denver, providing medical service for indigent Italians. The following constitute the board of trustees: Dr. Daniel S. Neuman, president; Dr. Charles H. McLean, secretary; the consul-general of Italy and Drs. Sherman T. Brown, Giuseppe Cuneo and Clare P. Conroy. The consulting staff is made up as follows: Drs.

---

[1] THE JOURNAL A. M. A., Sept. 8, 1906, p. 790.

Rodolfo Albi, Charles D. Spivak, Philip O. Hillkowitz, Amasa M. Bucknum and Pasquale De Cunto. The following make up the attending staff: Drs. Giuseppe Cuneo, Martin J. Waldron, Claud C. Keeler, Clare P. Conroy, Sherman T. Brown, Frank M. McCartney, Seymour D. Van Meter, Charles H. McLean and Orasio D. Abrahams; ear, nose and throat, Dr. Daniel S. Neuman; eye, Dr. Frederick A. Davis; nervous diseases, Drs. J. Elvin Courtney and Christian L. Neubert; diseases of the stomach, Dr. Charles D. Spivak; obstetrics, Drs. Rodolfo Albi and Thomas M. Burns; bacteriology, Dr. Thomas W. Hall, and *x*-ray treatment, Dr. George H. Stover.

State Society Meeting.—The program has been issued for the coming meeting of the Colorado State Medical Society, which will be held in the Albany Hotel, Denver, October 9 to 11. The first two days and the morning of the third day will be devoted to the reading of papers and discussions on general subjects, while the afternoon of the third day will be taken up by section work. For just one-half day, therefore, the whole society will be divided into sections, as follows: section on surgery, gynecology and orthopedics, of which Dr. Walter A. Jayne is chairman; section on internal medicine and nervous and mental diseases, of which Dr. James Rae Arniell is chairman; section on hygiene and sanitary science, of which Dr. Hugh L. Taylor is chairman, and section on ophthalmology, of which Dr. Edward Jackson is chairman. Judging from the titles of the papers the latter section includes the subjects of laryngology and otology. Dr. Richard Cabot, Boston, will deliver an address Wednesday afternoon on "Mind Cure: Its Service to the Community." The program contains abstracts for most of the papers announced, which gives those who desire to attend an idea of the probable scope of the papers to be read.

IDAHO.

State Society Meeting.—The fourteenth annual meeting of the Idaho State Medical Society will be held in Lewiston, October 4 and 5. The council will meet in executive session on the evening of October 3, and the scientific proceedings will commence at 10:30 Thursday morning. The headquarters will be the Lewiston Commercial Club. The annual banquet will be held at the Raymond Hotel Friday evening. THE JOURNAL has just received the program and finds the list of papers to be one promising an interesting meeting. Dr. J. B. Morris, Lewiston, is president, and Dr. E. E. Maxey, Boise, is secretary-treasurer.

ILLINOIS.

Diphtheria.—An epidemic at Bardolph, near Bushnell, has grown to such proportions that the authorities have ordered all schools and churches closed.

Physicians Ill.—Dr. William C. Hill, Murphysboro, is reported to be critically ill with typhoid fever.——Dr. Amos S. Bickel, North Chillicothe, is seriously ill with anemia, at St. Francis' Hospital, Peoria.——Dr. Wilbur J. Hawkins, Aurora, is ill with appendicitis at his home.

State Board Reports.—The State Board of Charities in its quarterly report, just issued, states that since the organization of the board last April, the commissioners have visited every hospital for the insane in the state, 52 county almshouses, 52 jails, 19 orphanage and child saving institutions; it has investigated the charges against the Soldiers Orphans' Home, Normal; the Soldiers Widows' Home, Wilmington, and the Asylum for Feeble-Minded Children, Lincoln, and has inspected the schools for the deaf and blind at Jacksonville, and the Soldiers and Sailors' Home, Quincy.

Coroners Meet.—At the annual convention of the Illinois State Coroners' Association, held in Chicago, September 11, 48 counties were represented. Peter M. Hoffman, coroner of Cook County, was elected president of the association; C. Z. Noel, Joliet, and C. N. Streeper, Alton, were elected vice-presidents; R. L. Baker, Peoria, was elected secretary, and William Woodruff, Springfield, treasurer. One of the most important matters brought up was the necessity of passing a law compelling physicians to report cases of a certain class to the coroner. There is nothing at present in the statutes to prevent a physician of Illinois from signing a death certificate, although he may not have attended the deceased in the capacity of physician for a number of years.

Chicago.

The Work of the Visiting Nurses.—During August the Visiting Nurses' Association cared for 1,227 patients, and the nurses made 5,738 visits.

Gift to Hospital.—It has been announced that Dr. D. K. Pearsons has donated an additional $5,000 toward the fund for the new Presbyterian Hospital, which brings the total fund to within $10,000 of the $400,000 required.

Fatal Error.—Anton P. Freund, druggist at St. Luke's Hospital, has been discharged from that institution as a result of his mistake in furnishing atropin instead of a proprietary preparation of a somewhat similar name in filling a prescription for a patient in the hospital, who died soon after. The coroner's jury recommended that Freund's license as pharmacist be revoked.

New Maternity.—A new site has been provided for the Chicago Lying-in Hospital and Dispensary, now located at 294 Ashland Boulevard, at the northwest corner of Vincennes Avenue and Fifty-first Street. The cost was $52,500, and the new hospital will be erected at a cost of between $150,000 and $200,000. The new hospital, with 60 beds, will be able to care for 1,200 patients a year.

Personal.—Dr. Alfred C. Girard, United States Army, retired, has been obliged to give up his plan of practicing in Chicago, on account of the serious illness of his wife, and has returned to the Pacific Coast.——Dr. George E. Baxter was held up and robbed of a gold watch and a small amount of money, September 12.——Dr. and Mrs. Julien E. Hequembourg have returned after a month's trip to the Pacific Coast.

Deaths of the Week.—During the week ended September 15, 548 deaths were reported, equivalent to an annual mortality rate of 13.94 per 1,000. The deaths for the preceding week were 515, and for the corresponding week of 1905, 514. Among the important death causes were: Acute intestinal diseases, 110; consumption, 55; Bright's disease, 43; heart disease, 41; violence, including suicide, 39; cancer, 34, and pneumonia, 30.

INDIANA.

Hospital Contracts Let.—The trustees of the Indiana Village for Epilepsy awarded the contracts for the first buildings to be erected on land recently purchased by the state at New Castle for $14,195.——The contract for building the Southeastern Indiana Hospital for the Insane, Madison, has been awarded at a price of $1,165,885.

Physicians Ill.—Dr. R. W. Martin, Washington County, was removed from his apartments at Lake James to the Wood Hospital, Angola, for the treatment of pulmonary abscess. He is in a critical condition.——Dr. Edward L. Elrod, Henryville, underwent operation September 5 for appendicitis at the Norton Infirmary, Louisville, and is recovering.

Personal.—Dr. Robert H. Ross, Cassville, has been appointed a member of the Howard County Council.——Dr. Albert C. Yoder has been elected secretary of the Goshen Board of Health.——Dr. Chester C. Funk has been elected secretary of the newly organized New Albany Board of Health.——The new board of health of Terre Haute met September 7 for organization and elected Dr. Thomas W. Moorehead president and Dr. Myron A. Boor, secretary.

Medical Colleges Open.—A mass meeting of the students of the Indiana Medical College and the medical department of Purdue University was held September 5 and constituted an informal opening of the fall term of the school. About 100 students were present, and Drs. Henry Jamison, Frank B. Wynn, Edwin F. Hodges, John F. Oliver, Albert E. Sterne, Theodore E. Potter and Alembert W. Brayton addressed the meeting.——The State College of Physicians and Surgeons, in affiliation with Indiana University, opened for regular work September 5, with 40 present. No formal exercises were held. An informal reception for the students was held September 5 in the college building, at which speeches were made by the president of the University, and Drs. Allison Maxwell, B. G. Myers, John F. Barnhill and James H. Ford.

MISSOURI.

Must be Vaccinated.—The board of health of St. Joseph has requested the school board to require all pupils to present certificates of vaccination before entering school.

Milkmen Fined.—Eight St. Louis milkmen were fined, September 12, for selling impure and adulterated milk. Two of these paid fines, one of $50 and the other of $25. The remaining six cases were appealed.

Impetigo, Not Leprosy.—Investigation of the case of supposed leprosy reported to the St. Louis board of health a few days ago, reveals that the case was one of impetigo contagiosa, and that the diagnosis of leprosy was erroneous.

countries that all India is infected is erroneous. For example, in the Bombay presidency and Sind, the section of India which is most affected, only 19 districts, and states and towns out of 108 are reported infected, and of the 19 places 15 furnish cases running from one to eleven.

Medical Bequests from a Physician.—The former professor of legal medicine and toxicology at Montpellier, France, Dr. Jaumes, who died recently, aged 72, made the medical faculty his universal legatee. A fund producing an income of $1,200 was left to found a chair of general pathology and therapeutics, and a prize in legal medicine was also endowed in both the medical and law departments. Another fund representing an income of $2,000 was left in charge for an aged relative, at whose death it reverts to the medical faculty, and $6,000 was presented to the local medical and other scientific societies.

Subscriptions for Schaudinn's Widow.—Committees have been organized in England, as well as in Germany, to solicit subscriptions toward a fund to be presented to the widow of the recently deceased young scientist, Fritz Schaudinn. Although only 35, his name is world famous from his discovery of the spirochete connected with syphilis, and this discovery had been preceded by several others of epoch-making importance in various fields of zoology, especially in the study of protozoa, sporozoa and hematozoa. He succumbed to the effects of an abscess in the pelvis June 22, as was duly chronicled in these columns at the time.

Fifth International Conference on Tuberculosis.—This assemblage convened at The Hague September 6. One of the chief subjects discussed was "Channels of Infection," and among others, Calmette of Lille reported the interesting conclusions of his research in this line. A brief summary of his work will be found on page 972 in this issue. He has found that not only tubercle bacilli, but also insoluble particles of mineral dust and pneumococci are able to pass promptly through the intestinal wall without leaving a trace of their passage, and are carried by the leucocytes to the lung. The accumulations in the lung afterward are more extensive than when the substances are inhaled directly into the air passages. A number of Americans were given a prominent part on the program, and their communications still further emphasized the importance of the work being done in this country.

LONDON LETTER.

(From Our Regular Correspondent.)

London, Aug. 31, 1906.

The Liverpool School of Tropical Medicine.

In view of the alarming nature of the recent reports with regard to the spread of sleeping sickness in Africa and of the fact that an expedition organized by the Liverpool School of Tropical Medicine has been studying this disease for three years in the Congo, Sir Alfred Jones, president of the school, requested an audience of the king of the Belgians in order to confer with him on the subject. Recently the king offered a prize of $40,000 for the person who should discover a remedy and placed a credit of $60,000 in the Congo estimates for the purpose of prophylactic research. He granted the request of Sir Alfred Jones and received a committee from the Liverpool school, which included the president, Prof. Ronald Ross, Professor Boyce, Dr. J. W. W. Stevens, Dr. J. L. Todd and Dr. Evans. The king gave a most attentive hearing to their views on the necessity of preventing the further spread of sleeping sickness. He agreed with Sir Alfred Jones that the question is one of international importance and said that as far as he is concerned he is prepared to do all in his power to relieve both the white and black population from this terrible scourge. He asked the Liverpool school to submit to him a scheme for the prevention of the disease, which will be done as soon as possible. He promised his coöperation if it is in any way feasible or practical. He expressed in high terms his appreciation of the energetic work now being carried on by the school and of the thorough manner in which its expeditions are worked. To show the value he placed on that work he bestowed the Order of Leopold on Professor Ross, Professor Boyce, and Dr. J. L. Todd, the last of whom worked on trypanosomiasis in the Congo Free State for three years.

The Diminishing Use of Alcohol in Hospital Treatment.

Sir Victor Horsley's statement at Toronto that alcohol is being rapidly superseded by milk in London hospital treatment is well borne out by accounts of Guy's Hospital. Not only is the general bill for alcoholic liquors diminishing, while the number of patients is increasing, but the beer bill is actually disappearing. Last year, when there were 8,626 in-patients under treatment, the expenditure on malt liquors was £8 12s 6d. In 1896, when there were 2,000 fewer patients, the bill was double this sum. So small is the amount of beer consumed at Guy's that for the first time in the memory of the management it has been considered not worth while to order the drink by the barrel and bottled beer has been substituted. The hospital patients are now consuming 100 gallons of beer whereas five years ago they consumed 512 gallons. At one time beer was considered an ordinary part of the patient's diet. That idea has now disappeared. The quantity of wines and spirits consumed shows a similar reduction.

The Anti-Malarial Campaign in the Federated Malay States.

The measures taken against malaria at Port Sweetenham, in the Federated Malay States, have been previously reported in The Journal. Dr. Hamilton Wright now reports great success. The port was designed by the government to replace that of Klang, on the upper tidal reach of the river of the same name. Port Sweetenham was jungle covered, flooded daily by tides and had an average rainfall of about 100 inches yearly. The district was a center of the worst forms of malaria. On the formal opening of the port Klang was abandoned and the river closed to sea-going vessels. Severe malaria immediately broke out among the officials and coolies employed on the railway and shipping. A commission was appointed, consisting of doctors, railway and works officials, to devise measures for the suppression of malaria and for the general sanitary improvement of the port. The recommendations of the commission involved an outlay of from $50,000 to $60,000 and were at once accepted by the government. The new port was dyked, drained, leveled and cleared. Since these measures were carried out there has been scarcely a case of malaria, and instead of being an unhealthy and shunned swamp, the port has become a desirable billet.

The Lot of the East End Doctor.

The onerous conditions of medical work in the east end of London are illustrated by the following advertisement which has appeared in the *Times:* "An east end medical man, B. A. (Cantab.), who has never had a day's holiday or a Sunday's rest since he has been in practice, and who has not sufficient capital to purchase a more comfortable living, would like to change his profession. He has taken honors in science, so judges himself capable of filling a post as analytical chemist. Having good credentials and references, he hopes that manufacturing firms, etc., will give his advertisement consideration."

VIENNA LETTER.

(From Our Regular Correspondent.)

Vienna, Aug. 28, 1906.

The Report of the Metropolitan Board of Health.

The annual report of the board of health of Vienna was issued a few days ago and gives a good insight into the interesting changes taking place in the capital, viewed from a medical standpoint. The area covered by the city is about 120 square miles, and the population for 1905 was 1,900,000. The number of medical practitioners was 2,500 active and about 500 not strictly practicing doctors (dental surgeons, hospital staff and purely scientific workers). The hospitals belonging to the state number 11, with about 6,000 beds, besides numerous asylums and children's homes. The number of the in-patients in state hospitals was upward of 60,000, and the number of out-patients was nearly a million and a quarter. The mortality rate in Vienna shows a constant though slight decline, and stands now at 18.7 per thousand. Tuberculosis in all forms is responsible for fully 15 per cent. of all deaths; it gives rise to the sad name of morbus Viennensis. In all other respects the mortality has been lowered with the exception of (perhaps) cancer, which is constantly increasing; perhaps the more definite means of diagnosis is responsible for this increase. The infant mortality was pretty high in some poor districts, but as a rule it hardly exceeded 160 per thousand. This compares not unfavorably with the figures for France, England and Italy. Not a single case of smallpox has been brought to the notice of the board for two years, and the last case seen in Vienna had been imported from Italy by a railway laborer. It is strange enough, that in the city where Kaposi once could make his famous studies on the histology of smallpox eruptions, 35 years later the young dermatologists have to study the disease from pictures and casts, from lack of actual cases. Compulsory vaccination has effected this change. The decline in diphtheria mortality is continuously noted in all cases in private and hospital practice. Two severe epidemics of measles, with a mortality of 8 per cent., and of influenza of the gastrointestinal type with complications in the middle ear, were noted during 1905, otherwise the year was singularly uneventful. The ratio of births was 1 in 950, and the annual increase of the population was 2.2 per cent.

Pharmacology

State Universities and the Public Health.

As will be seen by the following account, copied from the *Bulletin of the Kansas State Board of Health*, vol. ii, No. 7, the School of Pharmacy of the Kansas State University is making an examination of proprietary remedies when requested to do so by the Kansas State Board of Health. This is interesting and gives promise of better things. The departments of pharmacy and chemistry of state universities, supported by state funds, should do their share toward supplying information in regard to the composition of the many remedies proposed for use in the treatment of disease. In the past, these schools and departments have been restricted in their work because of insufficient appropriation, but now that the need of better protection of public health is being appreciated, as is indicated by the enactment of a national pure food and drug law, there should be little difficulty in securing more liberal support; especially, since the passage of this law has made it essential that each state establish control of foods and drugs manufactured for consumption within its boundaries.

The following is the report referred to:

"Several weeks ago a tragedy occurred near Ellinwood, in Barton county, which emphasizes the necessity of a curb on 'The Great American Fraud.' A letter from a physician in Ellinwood gives the pathetic facts in the case:

> " 'Louise Closen, aged sixteen months, while playing, secured a bottle containing tablets called "Vesitone," which an older member of the family was taking for bed-wetting. Her father does not know how many tablets were taken by the baby, but he thinks less than ten. Ten minutes after taking the medicine, the child became rigid in every muscle. The father gave it three-quarters of a teaspoonful of Winslow's Soothing Syrup. Two or three minutes later the father attempted to induce vomiting by giving salt-water and mustard, but did not succeed. The child was apparently unconscious from fifteen minutes after taking the tablets. A slight tremor was present during the whole time. Ten minutes after dying the spasm relaxed somewhat. The child died forty-eight minutes after taking the medicine.'

"The vesitone was sent to Professor Sayre of the State University for analysis, which is herewith submitted for the information of the public:

> " 'The report of analysis of a remedial agent sent us by the secretary of the State Board of Health, which was labeled as follows: "Vesitone for a Certain Cure of Kidney and Bladder Weakness, etc., manufactured by the Union Medical Company, Edwardsburg, Mich." The question by the secretary regarding this was: "Does the medicine contain poisonous ingredients?" Our examination shows that the tablets contain about one-twelfth grain of alkaloidal material in each tablet, of which a fair proportion is strychnin.'

"The following is taken from the wrapper, which sets forth the remarkable virtues of this nostrum:

> " 'It is a combination of a simple and harmless vegetable or herbal remedies that affects in a most wonderful manner the changes desired. Its action is directed so singly and directly to the affected organs that the cure is swiftly and surely accomplished without any shock whatever to the intricate organism of the most delicate child. It achieves its most marvelous results from the fact that it repairs and builds up the affected parts and organs in precisely the same way that they were weakened and broken down by the disease. The ingredients are so carefully chosen and so scientifically blended that there is absolutely no superfluous action, no organ is unnecessarily affected, and there is no irritation whatever from its use. In other words, it acts like a perfect antidote to the disease.'

"This statement, no doubt, was the occasion of the carelessness on the part of the parents in placing the remedy where the child might get it to play with. If this had been properly labeled, as containing a dangerous alkaloid, the parents would probably have exercised all necessary precaution to place it beyond reach of the little one.

"The coming legislature should enact a law compelling the manufacturers of all proprietary nostrums containing poisonous drugs to have the same distinctly set forth on the label, in order that people may be advised what they are taking. The coöperation of the physicians of the state is urgently requested in putting through a measure of this kind."

Character of Medicines Dispensed by Physicians.

The *Western Druggist*, in an editorial in the August issue, calls attention to the fact that though pharmacists are required by law to dispense drugs of a recognized strength and efficiency, there are no restrictions on physicians, who may dispense any and all remedies which they see fit to use. The editorial directs attention to the condition of affairs in Indiana, stating that it is an ideal state for the enforcement of laws in regard to pharmacy, because of the concentration of everything pertaining to medicine, food, hygiene and sanitation under one board and practically into the hands of the secretary, who has absolute jurisdiction over about 600 employés, unhampered by any political considerations. It then goes on to state that over one-half of the physicians in Indiana dispense their own medicines; that too often they procure their supplies from whomsoever will sell them most cheaply, and that nearly every city has one or more "fly-by-night" concerns, which, in order to get trade, undersell other dealers and often sell pharmaceutical preparations, such as elixirs, syrups, pills, etc., for less than the wholesale cost of the materials. Necessarily, the articles supplied by such concerns are liable to be below standard and could not be dispensed by a pharmacist without danger of prosecution and fine. An instance is quoted in which a physician had been giving a patient teaspoonful doses of a tincture of opium which he had purchased from one of these houses—the preparation probably being a weak solution instead of a reliable tincture—on giving the patient the same dose of a standard tincture of opium purchased from a druggist, opium poisoning resulted and the patient nearly died. This forcibly demonstrates, the drug journal says, that dispensing physicians as well as pharmacists should be required to use drugs of standard strength to obviate the danger to patients resulting from inaccuracy in dosage.

We are forced to acknowledge that there is much truth in the drug journal's comments. If physicians dispense their own medicines, they should be certain that what they use are reliable and of standard strength. As they are not able to test the preparations themselves, there is only one way by which physicians can have confidence in the preparations, and that is by obtaining them from reliable houses. But from recent developments, it would seem that it is not always easy to tell what houses are reliable. This much, however, must be admitted: Those concerns whose only claim is low prices for their products are not, as a rule, to be depended on. But if we mistake not the druggist is as likely to buy where he can cheaply as is the physician.

Whose Fault?

A certain pharmacist in San Francisco was, like so many others, burned out by the fire in April, relates the *California State Journal of Medicine*. He resumed business before the smoke had blown away, but on entirely new lines. He decided to run his store, for at least six months, as a purely prescription pharmacy, consigning nostrums, "patent medicines" and sundries to the outside place where they belong. His experience is most interesting. Within the first week a prescription for "antikamnia" was presented. It came not from a quack, nor from an infant in the profession, nor from an ignoramus, but from a physician of some standing in the community! Probably there has never been a more disgracefully but consistently dishonest and fraudulent nostrum foisted on our profession than this deadly "antikamnia," yet here is a physician, presumably a self-respecting gentleman, who continues to help along the fraud! And there were others as ignorant or as lazy who "prescribed"—forgive us the word—other nostrums, to the discouragement of the pharmacist who wanted to do the right. One day a woman came in with a prescription; it was filled and given her, but before leaving she asked for a bottle of a nostrum once popular with a certain class of physicians. Some kind friend had doubtless recommended it, and thus she was aiding (?) the physician. So it went until the shelves of the "prescription pharmacy" look about as much like a department store as though the effort for decency had never been made. The attempt to be clean and decent was defeated by the very men who should have supported it—the physicians!

Correspondence

The Attacks on the American Medical Association.

DETROIT, Sept. 14, 1906.

To the Editor:—As a contribution to a correct estimate of the criticisms in Association management, the following observations are presented:

1. There has always been criticism of the American Medical Association management, a criticism varying with its prosperity. In this it falls under the general law of powerful organizations. Someone is always ready, with a club, to hit the head of anyone who rises above mediocrity, so as to reduce him to the general level. Hence, no friend of the American Medical Association need be disturbed by wild criticism, criticism inspired by hostility to its fundamental principles.

2. The medical profession has never learned cheerful submission to the guidance of its leaders. Many are restive under any regulation essential to effective organization, criticising both the committees who make and the officers who enforce them. It seems an American characteristic to be "agin the givernment." Very slowly we are learning the value of medical organizations, and the necessity of meeting the conditions essential to their operation. Nor have we learned to follow any administration long without "kicking." We want change—without reason often—from the President of the United States down.

3. There is an obvious lack of faith, by many, in either the capability or honesty of such management. Grafters themselves, they suspect the management of using its opportunities to feather its own nest. But the vast majority, while not grafters, have suffered so much therefrom, that they are easily led to impute the worst motives to those outside their personal knowledge—hence many grades of criticism.

4. The business of the American Medical Association has grown to such enormous proportions that its success demands a concentrated administration. Twenty-six thousand members can not be consulted when a stock of paper is to be purchased or the weekly edition of THE JOURNAL mailed—one head must look after all subordinates, wherever working. He may gather about him a corps of councilors, in addition to those provided by the Association, but he must remain the head or be absolutely useless. To comprehend even a tithe of this business will tax the capacity of one who gives his entire attention thereto. Criticism not based on such intelligent grasp of the Association's business can hardly be classed among the valuable assets of a scientific person. Yet such criticisms are heard too frequently for the reputation of their authors.

5. The organization of the profession into a living unity presupposes a knowledge by each doctor of his place and work therein and his disposition to apply said knowledge. Little criticism of the management's shortcomings will be heard from those devoted to the cultivation of such knowledge and disposition, because all their energies are otherwise employed. The great need of our growing organization is "less talking, more thinking and doing."

6. The establishment of a "clearing-house for medical supplies of unknown composition," in the hands of a working board of acknowledged ability and integrity, has awakened widespread criticism from those whose illicit gains were endangered. But such criticism ought to rejoice every friend of scientific medicine, as it shows that the American Medical Association is committed to an oneness of thought and practice such as will command the world's respect. In this many confess that they "love the Association more for the enemies it has made."

7. In view of these and allied things, what answer can the management make to its critics? It can appeal to the standard of the great Teacher, "by their fruits shall ye know them." It can ask in what respect have we failed to bring forth in its season, each after its own kind? Never before in the world's history has a similar management exhibited results in any sense comparable with that of the American Medical Association—lack of space makes details impossible here.

8. Should outside members desire an investigation of the minute details of THE JOURNAL office, the management will welcome the same as an admirable means of answering unintelligent criticism.

9. Is it not possible to plan the general meetings so that all present may feel that they do just a little as a whole? Now each is a member of a Section, in which he may work as he pleases, but collectively, as individuals or sections, they are impotent.

10. Owing to the method of their selection, all members of the House of Delegates do not possess that peculiar knowledge or special training necessary to initiate wise moves for the good of the entire profession, hence its acts must be restricted to (a) selecting the management and (b) supporting its plans for the Association's prosperity. Thus the management, rather than the House of Delegates, is the tribunal to which new ideas relating to the Association should be presented. If it approves, the House of Delegates will confirm, and vice versa. This is the more important, as the management does business every day in the year, while the House of Delegates has only an ephemeral life of four days yearly.

11. Personally, I have found the management open to receive ideas from members, if presented in a helpful spirit, and ready to adopt them when convinced of their practical value. Hence it is suggested that each critic first present his criticism direct to the management, and later, if this fails, to the membership at large through the journals and societies.

It is hoped that all critics will follow the example of scientific students, viz., make sure they have made a real find in medical sociology by long study and reflection, ere bothering either the Association management or the medical public. So will the management have more time and energy to serve the Association, and the critic save his reputation as a careful student and logical thinker. LEARTUS CONNOR, M.D.

DETROIT, Sept. 11, 1906.

To the Editor:—Thanks for publishing my communication. The answer of Dr. Happel shows that it was justified. The elaborate answer brought out those very points that the members want to know, and will help to clear up the air, just as I intended it should. A few more explanations will satisfy everybody, and that is just what I want. The only objection I might have to Dr. Happel's answer is his repeated statements, when he compares our Association with a well-managed business. Ours is that to a limited extent. But our members are educated, intelligent beings, interested in every bit of work done, and have a right to know every detail and should not be compared with common, everyday stockholders of business institutions.

I still believe that the right way to conciliate "kickers" is to take the wind out of their sails, and open up everything, so that they can see the error of their views; in fact, that was my whole plea, my sole object. All members have the good of the Association at heart, but disagree about how to accomplish it. That is all. By a quiet, dispassionate discussion they will agree readily. Dr. Happel's answer contained a number of slightly ironical expressions at which I had to laugh. They are when he mentions Dr. Walker's name on several occasions. The fact is that Dr. Walker knew nothing about this communication, had absolutely nothing to do with it. I do not need inspiration from Dr. Walker or anybody else. "I paddle my own canoe." J. H. CARSTENS.

GREENVILLE, TEXAS, Sept. 10, 1906.

To the Editor:—I have just read Dr. Carstens' letter in THE JOURNAL, September 1, and wish to correct the statements made therein regarding the Walker resolutions. I do not know from whom Dr. Carstens could have gotten his impression that the Board of Trustees or the officers of the Association opposed the Walker resolutions. He certainly could not have gotten this idea from any member of the House of Delegates who was present at the time.

The moment the reading of the resolutions was concluded half a dozen men were on their feet (myself among the rest), trying to make motions. Dr. Jackson of Missouri was recognized by the President and moved to lay the resolutions on the table. This motion was immediately seconded by at least a dozen different men (myself among this number), was put to vote and carried unanimously, without any discussion whatever. I do not think there were more than three or four of the Trustees in the House at the time. Those Trustees who were present had no time or opportunity to express themselves favorably or unfavorably, as the House voted the resolutions down at once without discussion.

I voted to table the resolutions: 1. Because Dr. Walker had misunderstood the President's address when he said in his preamble that preceded his resolutions that he (the President) had indicated that there was a sentiment of uncertainty and distrust relating to the management of The Journal and sundry other matters, when the President had clearly shown in his address that there was no such sentiment except among those who were being shown up by the work being done by the Association, to-wit, the "patent-medicine" people and those working for them directly. 2. Because I considered them unnecessary, uncalled for, and not only a reflection on the Board of Trustees, but an insult to the intelligence of the members of the House of Delegates. The report of the Board of Trustees showed that this body had done its work in accordance with the instructions of the House, and we had full and satisfactory reports before us, and at the time the Walker resolutions were offered the Trustees had just satisfied the most exacting member in this regard.

Any man of ordinary intelligence would know that the rumors and gossip regarding maladministration were put in circulation by those who have an interest in disrupting the organization and causing dissension in our ranks. There could be no excuse in the mind of any intelligent member of the House of Delegates for such an investigation, and the only conclusion which I have been able to come to regarding the object of these resolutions is that they were introduced with the expectation that they would be voted down, thus affording capital for further insinuations. Evidently they are being put to the use for which they were intended. The evident feeling of the House of Delegates was that the resolutions were intended for ulterior purposes.

That the delegates did not want to discuss the matter is shown by the fact that they voted the resolutions on to the table without a word of discussion or objection from any one. Even the author of the resolutions apparently had no desire to discuss or defend them. The attempt to show that the officers or Trustees of the Association opposed the adoption of these resolutions is absolutely contrary to the facts.

C. E. Cantrell.

State Board Examination Statistics.

Columbus, Ohio, Sept. 4, 1906.

To the Editor:—In the statistics published in the Educational Number of The Journal, Aug. 25, 1906, we note some errors that affect the standing of the Ohio Medical University.

In Table A, "Physicians Examined by the State Boards During the Calendar Year 1905," the Ohio Medical University is credited with three examinations in West Virginia, with one failure. The facts are, two graduates were examined there in 1905 and both passed. Joseph Nathan Freilich, who had been a student and failed of graduation, session 1904-05, registered as a graduate and failed to pass the examination.

In the same table the Ohio Medical University is credited with two failures in Ohio. The only basis for this is that two of our graduates who took the examination were refused certificates for an alleged infraction of the rules. Their papers graded respectively 89 and 84 per cent. They took the examination again in the fall, passed with creditable grades and were given certificates. There was no question at any time of a lack of educational qualifications and the fact of certificates being refused does not mean an educational failure. It is not so recorded in the records of the board.

We appreciate fully the difficulties that beset the compilation of statistics and, therefore, do not call your attention to these errors in a spirit of unkindness. We ask, however, that they be corrected and the Ohio Medical University be given her proper standing. Very truly,

James U. Barnhill, Chancellor.
W. J. Means, Treasurer.

[The figures published in the tables referred to are not "errors," as our correspondents state, but are exactly as reported to us by the examining boards. We can not go back of these reports.—Ed.]

Miscellany

A State Board Examination Through a Frenchman's Eyes.—Dr. Ménager, a graduate of the Paris medical school, writes home entertainingly of his examination before the state board at Seattle, his communication being republished in the *Journ. de Méd. de Paris* for August 12. He had learned that the board would accept his replies written in French, on condition of his paying $15 for the necessary clerical work of translating. He relates that the candidates assembled in the "opera house," each with his diploma in a tin box under his arm, and the noise and commotion were indescribable. Finally, the jury took their places, each candidate took the oath, paid in $10 to the treasurer, and was informed in regard to certain formalities to get the rebate on his railroad ticket. A slip of paper with the questions was then handed to each one and they settled down to write. As places could not be found for all the candidates, the members of the examining board gave up their seats to them and sought places elsewhere. The president of the board took off his coat, as it was getting very warm, then his vest, and went around among the candidates in shirt sleeves and suspenders, and his example was gradually imitated by the other members of the board and finally by the candidates. This was such a contrast to the formality of such official examinations in France that the two French candidates could scarcely believe their eyes. Occasionally some of the members of the board or a candidate drank a glass of water from the Chamberlain filter in the center of the room, "always the same glass, there was only one!" "Oh, Parisian pontiffs," he exclaims, "where are the robes of state and the academic hoods!!" . . . "After each session the candidates themselves handed in their MS. to the secretary. Occasionally the president of the board would interpolate: 'Dear doctors, there is a vacancy for a physician at such a place; Dr. so-and-so wants an assistant; the widow of Dr. so-and-so wants to sell his office equipment; hotel so-and-so has reduced its rates for you doctors while you are here for this business; you will find good accommodations and a good table there.' Involutarily my memory recalled the formal professors of my days in France with new respect. They seemed very great and very dignified in comparison with the licensing board before me." . . . "The longer I live here, however," he adds, "the less I mind all this. Time is money here, and all the old-fashioned conventionalities take time, and they cut them out here." . . . "The members of the board shook hands with us all, promising a prompt decision, and in three weeks we received back our diplomas—for which they had given us a receipt—and the newspapers published the names of the successful candidates, about 75 out of the total 110. I ask myself whether France would have given so kindly a welcome to an American physician, not speaking French, and armed merely with his diploma from the medical school in Philadelphia, Baltimore or New York!"

Poisoning from Emanations of Phosphin from Commercial Ferro-Silicon.—The manufacture of a compound of iron and silicon by means of the electric furnace has acquired much importance in connection with the steel industries, and large cargoes are now transported from points at which water-power enables the electricity to be cheaply produced to the iron works at which the material is used. The following case of poisoning from this material was reported by P. Lehnkering, Duisburg, Germany, at the fifth annual meeting of the *Freie Vereinigung Deutscher Nahrungsmittelchemiker*, May, 1906: In March, 1906, a Rhine freighter car ried a cargo of wine, soap and ferro-silicon (the latter about 35 short tons) from Mannheim to a point convenient to the Krupp works. The ship had apartments for the crew as usual in the bow and two other apartments aft. The forecastle and one of the cabins were completely protected by partitions from any emanations from the cargo, but the other cabin was located over that part of the hold in which the ferro-silicon was stored, and emanations therefrom were constantly being inhaled by two children occupying that apartment. The children (aged, respectively, 6 months and 2 years and 6 months) became ill and were confined to bed shortly after leaving Mannheim, suffering from giddiness and vomiting. Arriving at Duisburg, after two days' journey, the children were taken ashore and a physician consulted, who made a diagnosis of "meat poisoning." Both patients died the next day. The parents who were on the ship, but who did not remain continuously in the children's cabin, were affected with headache and dyspnea only. A postmortem was made on the body of the younger child. It is stated to have given indications of death by asphyxia, but no detailed information was furnished. Analysis of the material showed it to be crude ferro-silicon which was emitting phosphin, due to the fact that the casks containing it had been exposed to rain shortly before loading. The source of this phosphin is the calcium phosphid produced by the interaction of the phosphorus and calcium present as impurities in the materials used. From his experiments Lehnkering estimated that the total cargo could produce 851 gm. of the gas. Chemical tests of materials from the body of the child gave negative results, but indicated that death was not due to inhalation of either of the carbon oxids. Investigation developed several fatal cases in adults as well as children, and also some cases of death of cats and dogs. In the above-detailed incident, a canary that was in the children's cabin died about the same time. As this product is now in considerable demand and as its method of manufacture (electric) is liable to force its production at a point distant from its application, the danger of its emanations becomes an important matter in ship hygiene.

Keep Up the Fees.—The following is from the *California State Journal of Medicine:* "Just another word or two on the, to the insurance companies, tiresome subject of fees for life insurance examinations. In the first place, remember that our agitation out here is making history. Some of the insurance companies are referring, rather contemptuously, to the fact that 'California and one or two southern states are the only ones in the Union where the cut in fees has not been accepted' in abject silence—presumably, also, with gratitude that the companies are so generous as to pay the examining physician anything. They are howling about 'coercion' and 'trades-union' methods, and the iniquity of requiring that all members of a county medical society shall be required to live up to a certain fee schedule. They also talk about the sacrifice of independence, etc. Do not let many words and high sounding adjectives disturb your natural equanimity. When it comes down to brass tacks, the insurance company must admit that $5 is a small enough minimum fee; indeed, many of the companies have already admitted it. Perhaps some of you take the *Medical Examiner and Practitioner*, a publication primarily intended for insurance examiners. This publication preserved a discreet silence, so far as we could observe, on the very important subject of fees, until after the Boston session of the American Medical Association. Since then the two issues which we have seen contained a considerable amount of matter referring to fees. In the July number is an editorial so skilfully constructed that it may disturb the reader. It attacks the American Medical Association for taking up the insurance fee question, and (mis) states that the Association has entered into an agreement with the companies to recommend Dr. A. against Dr. B. Don't you believe it. The Association is working for the benefit of each and every one of us, and the object of the special committee on insurance which was appointed at Boston, is to secure the readoption of the minimum $5 fee. The journal quoted says that it protests against the Association's trying to force the trades-union idea down the throats of the medical profession. That is all pure buncombe, and the *Examiner* knows it. The Association does not force anything on the profession, or any portion of it. When the Association does anything, it is because the demand has come up to the Association through the county or state organizations. So with this fee question; a number of county and state organizations sent memorials to the House of Delegates at the Boston session, asking the Association to take some action; and the Association acted most conservatively by appointing a committee to confer with the insurance companies and to try to adjust the matter. It is the county societies that are agitating the question, and it is eminently right that they should do so. Who ever said that the fundamental idea of the trades-union was wrong? Who is forcing organization on the medical profession? It is not being forced at all; medical men are coming to their senses and realizing that coöperation is better than conflict, that is all. Stick to your demands for a minimum fee of $5, and do not examine for less: you will win out, if you will have a little patience."

Formaldehyd Disinfection.—D. Base has subjected to experimental investigation the various methods of generating formaldehyd gas for purposes of disinfection, with a view to determine the amount of gas present in the air of the room after the use of the same amount and strength of formaldehyd solution with the various methods. The experiments were made on a room practically, although not absolutely air tight and on a summer's day when there was little wind. The air was drawn from the room through tubes containing potassium cyanid and the amount of formaldehyd estimated by determining the amount of cyanid remaining by precipitating with standard solution of silver nitrate and determining by titration the excess of silver nitrate. The results of the experiments (*Jour. Am. Chem. Soc.*, August, 1906), show that the various methods tested should be ranged in the following order so far as the amount of formaldehyd present in the air of the room is concerned:

1. Trenner-Lee retort. (Average yield, 46 per cent).
2. Autoclave. (Average yield, 42 per cent).
3. Permanganate-formalin, 300 gm. to 600 c.c. (Average yield, 37 per cent).
4. Sheet spraying. (Yield cannot be estimated).
5. Permanganate—diluted formalin in the proportion of 600 c.c. formalin, 300 c.c. water and 375 gm. permanganate. (Average yield, 32 per cent).
6. Kühn lamp, using 1,000 c.c. methyl alcohol as against 600 c.c. formalin in the other methods.

For simplicity and expedition, the permanganate-formalin method is preferable to all the others. Moreover, the quantity of formaldehyd gas can easily be increased by using more materials, which only requires a larger pail. The sheet-spraying method has the advantage of keeping up a steady supply of the gas so that the quantity at the end of twenty-two hours was only 2.75 per cent. less than that found ninety minutes after closing the room. Base quotes the conclusions of Werner (*Archiv. Hygiene*, 50, 305, 1904), as follows: 1. In all cases an average of 5 gm. of formaldehyd (absolute) per cubic meter (2.15 grains per cubic foot) should be present, with seven hours' action. 2. In exceptional cases, where loss of formaldehyd can not be avoided, or where numerous objects, or a good deal of matter of an organic nature which cannot be conveniently removed, are present in the room, the quantity should be doubled. 3. In all cases where the temperature is below 50° F., it should be raised; 68° to 77° F. is an efficient temperature. 4. The strength of the formalin should be known. Base's experiments indicated that there is danger of the formation of paraformaldehyd in the evaporation of formalin solutions which reduces the efficiency of some methods. On the other hand there is reason to think that the amount of moisture is a factor in the disinfectant action of formaldehyd, which is believed by some to settle in solution on the walls, furniture and other objects and to act in solution rather than in the form of gas. It is suggested that with the permanganate method more moisture might be introduced by the use of a tin or copper still. From the experiments of Base it appears that the amount of formaldehyd present in the air of the room was much lower than that required according to Werner, so that it is probable that the amount of material used in these experiments was too small for absolutely sure disinfection.

Marriages

Carl Groschner, M.D., Toledo, Ohio, to Miss Frieda Schillinger of Detroit, September 4.

Robert Clyde Lynch, M.D., to Miss Amanda Cecile Genin, both of New Orleans, August 23.

Sidney J. Eichel, M.D., to Miss Rose Bonn Reinhardt, both of Evansville, Ind., September 18.

Henry J. Perry, M.D., Boston, to Miss Winifred V. Freeman of Newark, N. Y., September 8.

Oliver Anderson Jeffrey, M.D., Weiser, Idaho, to Miss Maud Jeffrey of Chicago, August 25.

Harriette M. Collins, M.D., and William Arthur Lingham, both of Montrose, Colo., September 1.

John A. Cavanaugh, M.D., Chicago, to Miss Irene Cummings of Rock Valley, Iowa, September 12.

George W. Longenecker, M.D., Elsmore, Kan., to Miss Carrie L. King of Kansas City, Mo., August 13.

Robert Gardner Loring, M.D., Boston, to Miss Susan Douglas Merritt of Springfield, Ill., September 6.

Edwin Stanley Scharff, M.D., Plaquemine, La., to Miss May C. Milliken of New Orleans, September 18.

Clarence B. Norcross, M.D., Clairton, Pa., to Miss Clara Campbell of West Elizabeth, Pa., September 5.

Philip Merriman Egert, M.D., Holland Patent, N. Y., to Miss Allie Adelia Clarke of Utica, N. Y., September 6.

Nina W. Oliver, M.D., Lapeer, Mich., and Clifford S. McIntyre of Kalamazoo, at Walkerville, Ont., August 13.

Orin Russell Witter, M.D., Hartford, Conn., to Miss Gertrude Louise Clinton Hunt of Chaplin, Conn., September 5.

Elbert W. Blakeslee, M.D., Newport News, Va., to Miss Berkeley Ellyson of Norfolk, Va., at New York City, September 7.

Deaths

James H. Peabody, M.D. University of Georgetown, Washington, D. C., 1860; for many years a member of the American Medical Association; a charter member and once president of the Nebraska State Medical Association; some-time president of the Omaha-Douglas County Medical Society; a charter member of Omaha Medical College; emeritus professor of military surgery in the John A. Creighton Medical College; major and surgeon, U. S. V., in the Civil War, during which he served at Carver Hospital, Washington, and in charge of the U. S. Marine Hospital, St. Louis; as medical director of the Platte district of the Department of Missouri and later of the Department of the Platte; and then acting assistant surgeon, U. S. Army; formerly chief surgeon of the C. M. & St. P. Ry., Nebraska division, and consulting surgeon to the Union Pacific Ry.; one of the oldest practitioners of Omaha, died at St. Joseph's Hospital, Omaha, September 10, after an operation for prostatitis, from exhaustion, aged 73.

Everard D. Ferguson, M.D. Bellevue Hospital Medical College, New York City, 1868; a member and once vice-president of the American Medical Association; for three years surgeon at the Clinton prison, Dannemora, N. Y.; a member and first secretary of the New York State Medical Association and afterward president of the association; a member of the Rensselaer County Medical Society and the Medical Association of Troy and Vicinity; founder of the Samaritan Hospital, Troy, and one of the most prominent surgeons of New York State, who last April was tendered a dinner and presented with a loving cup by the Medical Association of Troy and Vicinity, of which he was the founder, died at his home in Troy, Septemer 8, from acute intestinal disease, after an illness of three days, aged 63.

John Theodore Heard, M.D. Harvard University Medical School, Boston, 1859, a member of the Massachusetts Medical Society; assistant surgeon of the Thirteenth Massachusetts Volunteer Infantry in 1861, and in May, 1862, made surgeon of the same regiment, and then successively brigade surgeon of the first brigade, second division, first army corps, surgeon-in-chief of the same division; medical director of the same corps; surgeon-in-chief of the artillery reserve of the army of the Potomac, and finally medical director of the fourth Army corps; who was taken prisoner during the battle of Gettysburg and was made brevet lieutenant colonel, U. S. V., March 13, 1865; a well-known physician of Boston, died at his summer home in Magnolia, Mass., September 2, aged 70.

Charles A. Ruggles, M.D. Vermont Medical College, Woodstock, 1854; a member of the State Board of Health of California for 15 years ; for four consecutive years president of that body; once vice-president of the National Conference of State Boards of Health, and selected to make a special report to that organization on leprosy; a delegate to the Pan-American Medical Congress in Mexico; a resident of Stockton, Cal., for 37 years, died at his home in that city, September 11, from heart disease, aged 77.

Leroy Milton Yale, M.D. Bellevue Hospital Medical College, New York City, 1866; a specialist on orthopedic surgery and pediatrics of New York City; at one time surgeon to Bellevue Hospital; a former editor of *Babyhood*, and an etcher of repute, died suddenly at his summer residence in Quissett, Mass., September 12, from cerebral hemorrhage, aged 65.

William Wilson Varick, M.D. Bellevue Hospital Medical College, New York City, 1876; a well-known practitioner of Jersey City; a member of the Hudson County Board of Health and visiting physician to the Jersey City Hospital, died at his home in Mersemere, Bergen County, N. J., September 8, after a prolonged illness from heart disease, aged 58.

Harvey Link, M.D. Kentucky School of Medicine, Louisville, 1862, a well-known practitioner of Millard, Neb., and for fifty years a practitioner of that place; a pioneer medical man of Douglas County, and at one time a member of the territorial legislature, died at his home in Millard, September 10, after an illness of one month, aged 82.

Melvin E. Page, M.D. Bellevue Hospital Medical College, New York City, 1889; a member of the Medical Society of the State of New York and of the Oswego Physicians' Society; a specialist on diseases of the eye and ear, died at his home in Oswego September 9, three days after an operation for appendicitis, aged 40.

Charles H. Hall, M.D. Pennsylvania Medical College, Philadelphia, 1855; for more than a quarter of a century a leading practitioner of Macon, Ga.; during the Civil War surgeon to the Forty-fifth Georgia Infantry, C. S. A., died at his home in Macon, from heart disease, September 9, after an illness of fifteen months, aged 70.

Edward W. Perkins, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1861; a practitioner of Dinwiddie County, Va., for 43 years; for many years physician to the Dinwiddie County Almshouse, died at his home near Reams Station, Va., September 4, after a protracted illness.

Wansor Wilson Weeks, M.D. Rush Medical College, Chicago, and Hering Medical College, Chicago, about 1898, of Steelton, Pa.; hospital steward during the Spanish-American War, died in the Sister's Hospital, Buffalo, N. Y., July 27, one week after an operation for appendicitis, aged 31.

William C. Hill, M.D. College of Physicians and Surgeons of Chicago, 1902; a member of the American Medical Association, and a prominent physician of Murphysboro, Ill., died at St. Andrew's Hospital, Carbondale, Ill., September 4, after an illness of five weeks, aged 25.

Alva F. Ward, M.D. Western Homeopathic College, Cleveland, 1860; said to have been the oldest practitioner of Jamestown, N. Y., died at his home in that city September 10, after an illness of a few hours, from injuries received in a fall from a street car, aged 72.

Jay W. Sheldon, M.D. Homeopathic Hospital College, Cleveland, 1864, formerly president of the New York State Homeopathic Medical Society, and a member of the State Board of Examiners, died at his home in Syracuse, N. Y., September 7, after a long illness, aged 69.

Frank Harvey Dunbar, M.D. University of Vermont Medical Department, Burlington, 1903, of Swanton, Vt., died at the Mary Fletcher Hospital, Burlington, September 5, after an operation for cholelithiasis, from which he had been suffering for two months, aged 37.

Maurice James Chase, M.D. Vermont Medical College, Woodstock, 1850, for half a century a prominent practitioner of Galesburg, Ill., died at the home of his daughter in that city, September 6, after a brief illness, due to the effects of a fall, aged 80.

Jane Hammond Murphy, M.D. Woman's Medical College of New York Infirmary, New York City, died at the Job Haines Home for the Aged, Bloomfield, N. J., from paralysis of the throat, March 28, after an illness of two or three days, aged 85.

George W. Fellows, M.D. Vermont Medical College, Woodstock, 1851, for many years a practitioner of Kewanee, Ill., died at his home in Creston, Iowa, September 6, from Bright's disease, after a long illness, aged 78.

Cecil A. Butler, M.D. Medical College of Indiana, Indianapolis, 1901, of Manatee, Fla., died at the home of his parents near Huntsville, Ind., from cerebrospinal meningitis, September 6, after a short illness, aged 30.

James F. Kelly, M.D. Medical Department of Western Reserve University, Cleveland, 1896, formerly assistant superintendent of the Cleveland State Hospital, died suddenly in New York City September 4.

William A. Smith, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1881, of Atlanta, Ga., died at the Tabernacle Infirmary in that city, September 8, after an illness of about three weeks, aged 48.

Elmer Beecher, M.D. Castleton (Vt.) Medical College, 1835; state senator from Chittenden County in 1860, died at his home in Burlington, Vt., July 16, from senile debility, after a short illness, aged 95.

William D. Walradt, M.D. Albany (N. Y.) Medical College, 1878; a practitioner of Castleton, N. Y., for more than 25 years, died in the Albany City Hospital, September 6, after an illness of two weeks.

Andrew J. Vann, M.D. Medical College of Georgia, Augusta, 1855, one of the oldest and most prominent practitioners of De Kalb County, Ala., died at his home near Porterville, September 4, aged 74.

John Stolze, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1865, of Reading, Pa., a surgeon during the Civil War, died at Lake Geneva, Wis., September 11, after a lingering illness, aged 73.

William A. Smith, M.D. Medical College of Alabama, Mobile, 1881. of Anniston, Ala., died at the home of his mother in Mexia, Ala., September 5, from tuberculosis, after an illness of several months.

Joseph H. Drake, M.D. Homeopathic Medical College of Missouri, St. Louis, 1874, died at his home in Des Moines, Iowa, September 8, after an illness of two years, from heart disease, aged 60.

Charles M. Billings, M.D. New York Medical College, New York City, 1867, one of the oldest practitioners of Nashua, Iowa, died suddenly from heart disease, September 4, at his home, aged 68.

Percy Earnest Wagar, M.D. Detroit College of Medicine, 1894; treasurer of the Island of Negros, P. I., and later transferred to Manila, died in Manila August 12, from hyperpyrexia, aged 36.

James D. Seymour, M.D. Harvard University Medical School, Boston, 1872, a practitioner of Whately, Mass., since 1878, died in a sanitarium in Brattleboro, Vt., September 11, aged 56.

Edgar A. Brooke, M.D. University of Maryland School of Medicine, Baltimore, 1887, formerly of Dillon, Mont., died at Bonner, Mont., September 3, from heart disease, after a short illness.

William C. Hamilton, M.D. Homeopathic Medical College, Philadelphia, 1861, for forty years a practitioner of Philadelphia, died at his home in that city, September 5, aged 63.

Charles B. Flint, M.D. New York Homeopathic Medical College and Hospital, New York City, 1890, died at his home in Watertown, N. Y., September 8, after a brief illness.

C. F. Champion, M.D. Louisville (Ky.) Medical College, 1891, a pioneer practitioner of Enid, Okla., died at Wichita, Kan., September 9, after an illness of several years.

Samuel Fernald, M.D. Hahnemann Medical College, Philadelphia, 1884, died at his home in Philadelphia from laryngitis, July 30, after an illness of nine days, aged 79.

William F. Wallace, M.D. Columbus (Ohio) Medical College, 1880, died at his home in Rochester, N. H., September 5, from heart disease, aged 56.

William H. Clark, M.D. Beach Medical College, Indianapolis, 1886; of Indianapolis; died suddenly in that city, from heart disease, August 30, aged 76.

Marcus P. Anthony, M.D. Atlanta (Ga.) Medical College, 1892, a practitioner of Lake Butler, Fla., died at Blue Ridge, Ga., August 24.

Narcissus Garand, M.D. Toledo (Ohio) Medical College, 1885, died at his home in Toledo September 6, from Bright's disease, aged 66.

Joseph Wolfgarten, M.D. National Medical University of Chicago, 1895, died at his home in Chicago, September 10.

Deaths Abroad.

Isidor Neumann von Heilwart, M.D., formerly professor of dermatology and syphilography at Vienna, died August 31, aged 74. He was professor of these specialties from 1873 to 1903, when he reached the age limit. His manuals on dermatology and syphilis and his great atlas of cutaneous affections are known everywhere. He has trained a number of promising pupils, among whom may be mentioned E. Finger, Rille, Glück, Ehrmann and Matzenauer.

A. Herzen, M.D., professor of physiology at Lausanne, died August 24, aged 67. He was born in Russia, but his scientific work was done in Switzerland. His published works were mostly devoted to the physiology of the stomach and brain, with numerous popular works on physiology, hygiene and school inspection. His pamphlet, "Hygiène et Moralité," has been translated into many languages, and the German translation has been officially commended to students in Germany. He wrote with equal fluency in the five principal languages of Europe.

THE REST CURE FOR NEURASTHENIA.

——, Fla., Aug. 31, 1906.

To the Editor:—I would appreciate advice concerning any, or the best literature concerning the Weir Mitchell treatment of neurasthenics. I understand he has no medical work out on this subject. I would appreciate it if you would put me on the right track to get a clear understanding in print of the so-called rest cure treatment.

N. A. P.

Answer.—The so-called "rest cure," employed with such success in properly selected cases of general nervous prostration, especially in thin, anemic, run-down women, and consisting primarily of a judicious application of isolation or seclusion, forced feeding, and passive exercise, is the outgrowth of the early observations of Samuel Jackson. It is to Weir Mitchell, however, that we are specially indebted for the elaboration and scientific systematizing of this line of therapy, and hence it is not infrequently spoken of as the "Weir Mitchell treatment." In 1877 appeared his little book, "Fat and Blood," in which the treatment was first systematically outlined. The book is still the authority on the subject. In 1881 he again elaborated the treatment in his "Lectures on Diseases of the Nervous System, Especially in Women," (second edition, 1885). Dr. Mitchell has discussed the treatment incidentally in many of his later writings. In 1883 the rest cure was strongly commended, elaborated, and made popular in Europe by W. S. Playfair of London in "The Systematic Treatment of Nerve Prostration and Hysteria." These essays of Mitchell and Playfair placed the treatment on a firm, scientific basis. Since this introduction of the rest cure it has undergone many minor modifications at the hands of many physicians, and its literature has grown enormously. The explanation of these numerous modifications lies in the fact that the diseases, such as neurasthenia, for instance, in which faulty metabolism is so obvious, are not all regarded in the same way by all physicians. A general outline of the treatment will be found in any of the larger works on nervous diseases, especially those of Beard, "Nervous Exhaustion;" Mills, "Diseases of the Nervous System;" Wood, the article on "Neurasthenia" in vol. v of Peffer's System; Oppenheim, "Diseases of the Nervous System;" Dana, "Text-Book of Nervous Diseases;" Mettler, "Diseases of the Nervous System;" and others. The current literature on the subject is so extensive that an adequate list of it here would occupy too much space. Our correspondent is referred to the Index to Current Medical Literature which appears in The Journal in the last issues of June and December.

The purpose of the treatment is "to renew the vitality of feeble people by a combination of entire rest and excessive feeding, made possible by passive exercise obtained through the steady use of massage and electricity." Six weeks or more of seclusion from friends and relatives are enjoined. Absolute mental and physical rest in bed is insisted on. Daily massage, bathing (where partial rest is in use) and electricity are administered. Selected, regularly-given food, and appropriate tonics, with symptomatic medication complete the régime. It is obvious that there is possible a wide latitude in the exhibition of this line of treatment. For this reason it is capable of doing great harm as well as great good. It can not be employed by any rule-of-thumb. The principles underlying it and the ends sought for in the particular case in hand must be clearly defined in the medical attendant's mind. This being given and the cases carefully selected, we have in the so-called rest cure of Weir Mitchell, a most powerful and successful therapeutic measure.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Sept. 15, 1906:

Wales, Philip G., surgeon, on the expiration of his present leave of absence, ordered to Fort Wayne, Mich., for duty.

Woodall, Wm. P., asst.-surgeon, granted ten days' leave of absence.

Torney, Geo. H., deputy surgeon-general, having completed the duty for which he was ordered to Washington, D. C., will return to his station.

Brechemin, Louis, Jr., asst.-surgeon, ordered to proceed from *Camp of Instruction*, American Lake, Washington, to Seattle, Wash., for duty on the transport *Buford*, en route to Honolulu, H. T.

Crabtree, Geo. H., asst.-surgeon, advanced to the rank of captain from Sept. 5, 1906.

Lyster, Theo. C., asst.-surgeon, left Ancon, Canal Zone, Isthmus of Panama, en route to the United States, on leave of absence.

Noble, R. E., asst.-surgeon, leave of absence further extended 21 days.

Ragan, Chas., asst.-surgeon, the leave of absence granted in S. O. p, Sept. 3, 1906, Army and Navy Gen. Hosp., Hot Springs, Ark., was extended five days.

Lewis, Wm. F., asst.-surg., ordered to proceed from Chicago, to Fort Sheridan, Ill., for temporary duty.

Ashford, B. K., asst.-surgeon, ordered to accompany Second Battalion, Corps of Engineers, from Camp of Instruction, Mt. Gretna, Pa., to Washington Barracks, D. C.

Murray, Alexander, asst.-surgeon, granted 10 days' leave of absence.

Woodruff, Chas. E., surgeon, granted 15 days' leave of absence.

Porter, E. H., contract surgeon, arrived at Fort Reno, Okla., for temporary duty.

Stearns, C. H., contract surgeon, left Fort Monroe, Va., on 7 days' leave of absence.

Ware, Wm. H., dental surgeon, left San Francisco, for Manila, P. I., for duty in Philippines Division.

Jenkins, F. E., contract surgeon, left San Francisco, for Manila, P. I., for duty in Philippines Division.

Jordan, E. H., contract surgeon, left San Francisco, for Manila, P. I., for duty in Philippines Division.

Baker, C. L., contract surgeon, leave of absence extended one month.

Sanford, J. L., contract surgeon, leave of absence extended one month.

Stone, F. P., dental surgeon, granted leave of absence for 14 days.

Van Kirk, H. H., contract surgeon, granted leave of absence for one month.

Wolven, F. H., dental surgeon, will proceed from Fort Trumbull, Conn. (via Fort Jay, N. Y., for temporary duty for a period of 14 days) to Fort Monroe, Va., for temporary duty for a period not to exceed 2 months.

Mead, J. A., contract surgeon, returned to duty at Watertown Arsenal, Mass., from leave of absence.

Stanton, S. C., contract surgeon, left Headquarters, Dept. of the Lakes, Chicago, on 6 days' leave of absence.

Richardson, W. H., contract surgeon, returned from duty with Field Hospital, Camp of Instruction, Fort Benjamin Harrison, Ind., and assigned to duty to accompany 10th Battalion, Field Artillery, to Michigan City, Ind., for target practice.

Hereford, J. R., contract surgeon, left Fort Caswell, N. C., for Fort Screven, Ga., for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending September 15, 1906:

Moore, J. M., surgeon, detached from the *Puritan* when out of commission; to *Franklin*, Navy Yard, Norfolk, Va.

Bell, W. H., surgeon, detached *Nevada*, to home and wait orders.

Lumsden, G. P., surgeon, detached *Minneapolis* when out of commission; to home and wait orders.

Payne, J. H., Jr., P. A. surgeon, detached *Arkansas*; to home and wait orders.

Iden, J. H., P. A. surgeon, detached *Florida*; to home and wait orders.

Geiger, A. J., P. A. surgeon, to Naval Hospital, Mare Island, Cal.

Farwell, W. G., asst.-surgeon, detached *Worden* to *Connecticut*.

Lee, A. E., asst.-surgeon, detached Naval Hospital, Mare Island, Cal., to Medical School, Washington, D. C.

Mears, J. B., asst.-surgeon, detached *Minneapolis* to *Worden*.

Percy, H. T., surgeon, detached Naval Hospital, Yokohama, Japan, to home and wait orders.

Minter, J. M., asst.-surgeon, to Naval Hospital, Norfolk, Va.

Huff, E. P., acting asst.-surgeon, to Naval Hospital, New York.

Steele, J. M., medical inspector, to Naval Recruiting Office, Cleveland, Ohio.

Hibbett, C. T., medical inspector, to U. S. R. S. *Franklin*.

Wentworth, A. R., surgeon, to U. S. S. *Louisiana*.

Schaller, W. F., asst.-surgeon, and Longabaugh, acting asst.-surgeon, to the U. S. Naval Medical School, Washington, D. C., Sept. 29, 1906.

Munger, C. B., asst.-surgeon, to Naval Station, Guam, L. I.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending September 12, 1906:

Geddings, H. D., asst. surgeon-general, granted leave of absence from Sept. 15 to 30, 1906, both days inclusive.

Sawtelle, H. W., surgeon, placed on "waiting orders," to date from Sept. 5, 1906.

Godfrey, John, surgeon, directed to report to chairman of board of medical officers, Washington, D. C., Sept. 13, 1906, for physical examination.

Wertenbaker, C. P., surgeon, granted leave of absence for seven days, from Sept. 15, 1906.

Wickes, H. W., P. A. surgeon, granted two days' leave of absence, from Sept. 11, 1906.

Earle, B. H., P. A. surgeon, relieved from duty at Columbia River Quarantine Station and directed to proceed to Charleston, S. C., and assume command of the service.

Smith, F. C., asst.-surgeon, granted leave of absence for two days, from Sept. 4, 1906, under Paragraph 191 of the Regulations.

Fogarty, J. N., acting asst.-surgeon, granted leave of absence for seven days.

Kimset, W. A., acting asst.-surgeon, granted leave of absence for thirty days, from Sept. 10, 1906.

Jackson, J. M., Jr., acting asst.-surgeon, granted leave of absence for ten days, from Aug. 14, 1906.

Jackson, J. M., Jr., acting asst.-surgeon, granted leave of absence for four days, from Sept. 2, 1906.

McConnell, A. P., acting asst.-surgeon, granted four days' leave of absence, from Sept. 10, 1906.

APPOINTMENTS.

Dr. William W. Miller, of Tennessee, commissioned (recess) as asst.-surgeon, Public Health and Marine-Hospital Service, Sept. 4, 1906.

Dr. Robert A. C. Wallenberg, of Michigan, commissioned (recess) as asst.-surgeon, Public Health and Marine-Hospital Service, Sept. 4, 1906.

BOARD CONVENED.

A board of officers was convened to meet at the bureau, Washington, D. C., Sept. 13, 1906, to determine whether or not the physical condition of Surgeon John Godfrey is such as to entitle him to "waiting orders." Detail for board: Asst. Surgeon-General H. D. Geddings, chairman; Asst. Surgeon-General J. M. Rager; Asst. Surgeon-General J. W. Kerr, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon-general Public Health and Marine-Hospital Service during the week ended Sept. 14, 1906:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, Aug. 25-Sept. 1, 3 cases.
North Dakota: State, July 1-31, 8 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, July 21-28, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, June 1-30, 177 deaths.
Brazil: Bahia, July 28-Aug. 11, 6 cases, 2 deaths; Pernambuco, July 15-31, 4 deaths.
Gibraltar: Aug. 19-26, 1 case.
Italy: General, Aug. 8-16, 3 cases.
Panama: Colon, Aug. 19, 3 cases.
Turkey: Constantinople, Aug. 12-19, 1 death.

YELLOW FEVER.

Cuba: Habana, Aug. 10, 1 case.
Guatemala: Gualan, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, July 14-28, 126 cases, 115 deaths; Provinces, 968 cases, 704 deaths.

PLAGUE.

Australia: Cairns, July 14-21, 1 case; Sydney, July 7-14, 1 case, 1 death.
Brazil: Bahia, July 28-Aug. 4, 1 case, 1 death; Rio de Janeiro, July 7-15, 2 cases.
Egypt: Alexandria, Aug. 10-14, 3 cases, 2 deaths; Port Said, Aug. 11, 2 cases; Suez, Aug. 11-16, 3 cases, 2 deaths; Garbieh Province, Aug. 13, 1 case, 1 death.
India: General, July 14-21, 959 cases, 796 deaths.
Japan: Formosa, Aug. 1-10, 3 cases, 6 deaths.

Society Proceedings

COMING MEETINGS.

Medical Association of District of Columbia, Washington, Oct. 2.
Idaho State Medical Society, Lewiston, Oct. 4-5.
Colorado State Medical Society, Denver, Oct. 9-11.
Delaware State Medical Society, Wilmington, Oct. 9.
Medical Society of Virginia, Charlottesville, Oct. 9-11.
Kentucky State Medical Association, Owensboro, Oct. 10-12.
Vermont State Medical Society, Barre, Oct. 11-12.
American Association of Railway Surgeons, Chicago, Oct. 17-19.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fifteenth Annual Meeting, held in Buffalo, N. Y., Sept. 11-14, 1906.

The President, Lieut.-Col. Albert H. Briggs, N. G., N. Y., in the Chair.

The meeting was called to order by the president, who informally welcomed the association to Buffalo and gave notice that the formal welcome would be extended at a meeting to be held the same evening in the Y. M. C. A. building.

Reports.

The executive council reported the election of members during the year, and submitted the proposed amendments to the constitution providing for the establishment of a class of affiliated members containing the United States pension examining surgeons, the medical officers of the United States revenue service, and of the other government services and other persons interested in military medicine and surgery; providing that the corresponding members should report at the end of each year to the secretary, informing him of any change of address or title, the penalty for failure to so report being suspension, and providing that the honorary members should report to the secretary at the end of each year notifying him of any change of address or location. The executive council also recommended a change in the by-laws whereby the name of the official organ should be changed from the *Journal of the Association of Military Surgeons of the United States* to *The Military Surgeon*, with the subtitle reading, *The Journal of Military Surgeons of the United States.*

During the year 91 members have been added and 9 have died.

Award of Enno Sanders Prize.

The Enno Sanders prize medal was awarded Major James Evelyn Pilcher, the secretary, whose essay was entitled, "The Best Training of the Medical Officer of the State Forces to Qualify Him for Local Service and Mobilization with National Troops." The author summed up the subject as follows:

1. There is need of special study on the part of the medical officers of the National Guard and state troops to fit themselves for work in their own forces, not only in local service, but in connection with the national services in time of war and in peaceful mobilization.

2. The most essential feature in the effort to secure harmonious action with other state troops and with the national forces is uniformity of training, particularly along the lines of medico-military administration.

3. The most important element of the medical officer's training is confessedly the highest grade of efficiency in military hygiene, medicine and surgery. But of great importance and overlapping these to a considerable degree is a familiarity with medico-military administration, without which, indeed, the proper practice of military medicine, surgery and hygiene will be impossible. The medical officer must become deeply acquainted with the proper methods of selecting recruits; he must be able to control his men, commanding respect, not only of the hospital corps, but of the sick under his direction; he must be an authority beyond dispute on camp location and organization; he must understand the principles and practice of field hospital construction and composition; he must have experience in the instruction and drill of the sanitary soldiers, and be must be prepared to protect his service and assist his comrades by a thorough acquaintance with the records of his department.

4. To crown all these and to add to his efficiency in every respect, there must have developed in him an enthusiasm based on loyalty to the nation and interest in his profession, which shall impel him at all times to labor unceasingly and incessantly for the good of the service which has honored him with its commission.

By pursuing, then, these lines of work and thought, the medical officer of the National Guard of the United States will find his department *semper paratus* for all the emergencies of peace within the limits of the commonwealth which he is serving, and ever ready, in case the dark clouds of national or international conflict should overshadow the horizon of the nation's glory, to at once unite and coalesce with the forces which the mother country has maintained as a nucleus about which all military operations shall center.

Public Meeting.

The public meeting to welcome the association was held in the auditorium of the Young Men's Christian Association building on the evening of September 11, chairman of the committee on arrangements, Hon. Herbert P. Bissell, presiding. Addresses of welcome were delivered on the part of the city o: Buffalo by the acting mayor, Hon. Louis P. Fuhrman; on be half of the medical profession by Major Roswell Park; on be half of the state of New York by Hon. Rowland B. Mahaney and on behalf of the Association of Military Surgeons of th United States by the president of the association, Lieut-Co Albert H. Briggs.

Foreign Delegates.

The foreign delegates were then presented with the insigni of the association by the secretary, who accompanied eac presentation with appropriate remarks.

The following delegates to the association from foreig countries were present:

China—Surgeon-Captain Ho Ken Yuen, Imperial Navy; Surgeo: Major Tchau Shi Wa, Imperial Army, and Surgeon-Captain K Sha Chow, Imperial Army.

Mexico—Major Alejandro Ross, C.M.-M.M.

Great Britain—Major Arthur Gaskell, staff surgeon, Royal Nav: Lieutenant-Colonel William Grant Macpherson, Royal Army Medic Corps and Colonel William John Read Rainsford, Royal Arı Medical Corps.

India—Major W. H. W. Elliot, I. M. S.

Guatemala—Colonel Ramon Bengoecha, chief of the Medical I partment of the Army.

Nicaragua—Surgeon-General J. Lysandro Medina.

France—Colonel Henri Mareschal, chief surgeon of the garris of Paris.

Canada—Lieutenant-Colonel George Henry Porke and Major H. Delaney.

Italy: Lieutenant Giacomo Tartaro, surgeon Royal Army Reser

Election of Officers.

The following officers were elected: President, Col. Vale Havard, assistant surgeon-general, U. S. Army; vice-pre dents, Rear Admiral Presley M. Rixey, surgeon-general U. Navy; Col. George Tully Vaughan, late U. S. P. H. and M. Service, and Col. Joseph K. Weaver, N. G. Pa., Norristov Pa.; secretary, Major James Evelyn Pilcher, U. S. A., Carlis Pa. (re-elected); assistant secretary, Capt. J. Carlisle Vries, N. G. N. Y.; treasurer, Major Herbert A. Arnold, N. Pa. (re-elected).

After discussion of Atlantic City, Denver, Pittsburg, M waukee and the Jamestown Exposition, it was decided to h the 1907 meeting in Norfolk, Va., at a date to be fixed by executive council.

(*To be continued.*)

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Sixteenth Annual Meeting, held at Salt Lake City, Uta Aug. 30 Sept. 1, 1906.

(*Continued from page 885.*)

Principles and Mechanics of Abdominal Drainage.

Dr. R. C. Coffey, Portland, Ore., presented the follo deductions: "1. Fluids are rapidly absorbed by the perito cavity; crude or granular matter only through lymph sı at the diaphragm. 2. A drainage tract always contains m organisms. 3. Any form of drainage is isolated from the peritoneal cavity in six hours. 4. A drain causes a flo serum by irritation which is profuse in proportion to amount of drain within the peritoneal cavity. 5. This is delivered to the surface only in proportion to the amou drainage passing out through the wound. 6. Serum an accumulate around drainage only when the drainage a outlet is less than that contained inside, or is not suffici extensive to deliver the fluid before it is filled with and granulations. 7. Blood and pus are never found i neighborhood of a properly applied drain after 48 hour The flow of serum dissolves blood clots and thick pus, le the gauze clean and white by the time it ceases. 9. Th of serum does not occur to any extent in formed abscess ties; therefore, blood and pus are not well drained from by capillary drainage. 10. A tube will drain a walled and will drain the peritoneal cavity under the influence of gravity, but not otherwise. 11. A single tube is much more likely to be choked by intestines and omentum than two or more parallel tubes. 12. Gauze drains in proportion to the amount coming through the opening, and will only drain when it is in contact with dressings or clothing, or when its outside end is at a lower level than the cavity to be drained. 13. Small gauze drains are likely to be choked at the exit, unless covered by a tube or protective. 14. There are three cavities of the peritoneum to be drained, the right and left flank separated from each other by the spinal column, and the pelvis separated from the flanks by the psoas muscles. Either flank holds more fluid, and is an inch deeper than the pelvis, and its bottom is more than four inches below the top of the divide made by the psoas muscle on which the appendix rests. The body must be elevated to an angle of 51 degrees to bring the bottom of the flank on a level with the divide, and 60 or 70 degrees to properly drain by the Fowler position. The entire cavity can be drained by gravity by a lateral position. 15. Drainage should always be in contact with the parietal peritoneum on one side. A line drawn from the center of the perineum to the tip of the shoulder passes through the pelvis and deepest part of the flank and on the right side through the appendix. These diagonal lines we call the right and left drainage lines. Drainage should always be placed external to these lines or just above the pubic bone. 16. If only one of the three cavities is infected, it alone should be drained."

Massage of the Heart in Apparent Death from Anesthetics.

Dr. D. S. Fairchild, Des Moines, Iowa, reported a case of massage of the heart in apparent death from anesthesia, and reviewed the literature of 24 other reported cases. He spoke of the time after arrest of the heart when positive results might be expected. He discussed the best route for approaching the heart for the purpose of massage.

Technic of Laminectomy.

Dr. Harry M. Sherman, San Francisco, discussed the relative merits of the simpler form of the operation as contrasted with the osteoplastic method, endeavoring to answer the question: Is the complex operation, with its sacrifice of motor nerves and its cutting of muscles for the sake of saving the laminæ, worth while? In general, this question was answered in the negative, but certain conditions were pointed out, as in the case of pressure paraplegia of vertebral tuberculosis with a right angle kyphos, in which the preservation of the laminæ, as a support for the longitudinal spinal muscles, might be essential for the complete and permanent relief of pressure on the cord, and in such cases the osteoplastic method might find a satisfactory use.

Peripheral Versus Intracranial Operations for Tic Douloureux.

Dr. Charles H. Mayo, Rochester, Minn., said that one of the most distressing diseases is facial neuralgia. More methods of internal, external and surgical treatment have been advanced for its cure than for any other condition. In 1896 Dr. Abbe reported a case in which he interposed mechanical obstruction to the reunion of the nerve by placing rubber tissue over the foramina of exit of the nerves in the skull. For nine years Dr. Mayo has employed silver screws to obstruct the infraorbital foramen after torsion, removal of the nerve by the Thiersch method. For a less period the inferior dental canal has been obstructed with equal success. While not as effectual as the intracranial operation, because of the numerous branches, still the method controlled the two branches most commonly affected. It can be employed on many who would not submit to the intracranial operation, with its attendant mortality and occasional failures to cure.

Aneurismal Varix.

Dr. J. Clark Stewart, Minneapolis, reported an interesting case of large aneurismal varix of the forearm, and exhibited photographs. He presented a history of such cases, and described the operative methods used. He likewise discussed the proper treatment of the lesions in the upper and lower extremities, and considered the radical difference in the conditions present.

Sarcoma of the Male Breast.

Dr. F. Gregory Connell, Salida, Colo., reported this case. The patient was 25 years of age. The mother had both breasts removed for cancer. There was no history of traumatism. The tumor started in a congenital discoloration of the skin near the right nipple, and in three months had grown to the size of a walnut. The breast and axillary glands were removed. The healing of the wound was perfect. Two months after discharge the patient presented himself for examination, and a keloid was found to have developed in the cicatrix. When last seen, six months later, the keloid was smaller, and there was no evidence of a recurrence of the sarcoma. Histologic examination showed the tumor to be a spindle-celled sarcoma.

Malignant Complications and Degenerations of Uterine Fibromyomata.

Dr. Charles W. Oviatt, Oshkosh, Wis., presented the following conclusions: 1. Women suffering from fibroid disease of the uterus incur a greater risk in allowing it to remain than in having it removed by a competent surgeon. 2. The fact that adenocarcinoma of the body of the uterus occurs much more frequently in cases of fibroid tumor than does cancer of the cervix, leads him to believe that there must be a direct causative relation between fibroid tumors and cancer of the body of the uterus. 3. Every fibroid tumor removed should be subjected to careful laboratory study, no matter what its gross appearance.

Treatment of Tuberculosis of the Kidney and Bladder by Nephrectomy.

Dr. Leonard Freeman, Denver, after detailing 14 cases on which he had operated for tuberculosis of the kidney and bladder, drew the following conclusions: 1. Tuberculosis of the urinary tract very often begins in the kidney, attacking the bladder secondarily. 2. It is usually at first unilateral. 3. Medical or climatic treatment is unsatisfactory in most cases. 4. The ideal treatment is early nephrectomy, providing there is one sound kidney. 5. Tuberculosis elsewhere, unless far advanced, is not a contraindication to operation. 6. Tuberculosis of the bladder derived from one kidney is positively benefited by nephrectomy, and can seldom be cured without it. 7. The demonstration of tubercle bacilli in the urine often fails. 8. The removal of the ureter is not ordinarily indicated. If sinuses result, they nearly always heal with time.

Dr. A. H. Kerr, Salt Lake City, reported a case of ureteral cystostomy or uretero-vesical implantation.

Operative Procedures for Chronic Urethritis.

Dr. A. C. Stokes, Omaha, discussed the incurable gonorrheas in the male. He gave the reasons why this disease is so often not cured. He spoke of the havoc of gonorrhea in civilization. A minute anatomic and pathologic diagnosis must be aimed at, and having once arrived at a definite diagnosis as to the position of the infection, we should resort to the methods that are most applicable to its treatment. He spoke of external urethrotomy in its relation to chronic gonorrhea, and of operating for vesiculitis, prostatitis and old infections in the vas deferens. He reported 4 cases where chronic gleet was treated by external urethrotomy and cauterization of the prostatic follicles and urethra. He discussed vasotomy in the treatment of infections of the seminal vesicles and epididymis. He described the technic of the latter procedure and reported 5 cases in which he had operated.

The following papers were also read: "The Control or Elimination of Pneumothorax During Operations on the Chest" (with lantern slides), by Dr. Dudley Tait, San Francisco; "Abdominal Contusions," by Dr. William Jepson, Sioux City, Iowa; "A Point in the Technic of Ligating the Appendix in Appendectomy," by Dr. Jabez N. Jackson, Kansas City, Mo.; "Intestinal Suture," by Dr. A. F. Jonas, Omaha; "Complications and Sequelæ of Prostatectomy," by Dr. J. N. Warren, Sioux City, Iowa.

The election of officers was reported in The Journal, September 8, page 788.

BRITISH MEDICAL ASSOCIATION.

Seventy-fourth Annual Meeting, held in Toronto, Ontario, Aug. 21-25, 1906.

(Continued from page 886.)

SECTION ON STATE MEDICINE.

Hygiene of the Home.

Dr. John J. Cassidy, Toronto, a member of the Ontario Board of Health, offered in his paper many practical suggestions for the perfection of the hygiene of the home. The first requirement is a dry site, and the ideal situation is one in which the sunlight may penetrate at some time during the day into every room of the house. The basement should extend beneath the entire house, with windows extending nearly to the top of the wall, so that space may be given for the expulsion of gases arising from the decaying and putrefaction that is continually going on in the soil. A floor of six inches of closely packed clay forms a good resistant and is more impervious to the passage of gases than solid concrete. Moderately hard well-burned brick is, he believes, the most suitable material for outside walls, and a coating of paint will prevent rain from soaking in the brick. Good plaster is the best for walls, and wall paper should be avoided. Kalsomine offers much less obstruction than paint or wall paper to the air. Ample openings for light and a good circulation of air are needed; all doors and windows should extend high up toward the ceiling. The advantage of a chimney in a room which facilitates the escape of impure air and the entrance of fresh air was referred to. The basement and the kitchen, which are in a way the most important parts of the dwelling, should naturally receive more frequent attention than the living rooms, where presumably organic filth is less likely to gain access. Cleanliness in the kitchen is necessary, sewage should be kept under cover and frequently removed, and the rooms should be ventilated automatically. The bed chamber should contain no carpets, but only a washable rug near the bed. The waxed floor should be mopped every morning with a damp cloth, and the walls painted with white enamel paint. The window curtains should be of cotton or some washable fabric, and frequently laundered.

Medical Inspection of Schools.

Dr. Helen MacMurchy, Toronto, referred to the government indorsement in Great Britain of the medical inspection of schools and pupils, which the country had consequently adopted. The day had come when there must be the greatest possible coöperation between the teacher and the medical profession, and it was important that the medical inspection should be made by qualified medical practitioners who should be properly remunerated. Inspectors need special training and many of the colleges are now giving instruction along this line. The first step in advancement consists in the modification of existing conditions, and both the pupil and the parent should be impressed with the importance of cleanliness, pure food, pure air and good health. Children of the poor should get enough to eat to bring about that development necessary for good health and consequent good citizenship. The importance of hygiene can not be overestimated.

Mr. William Scott, B.A., principal of normal schools, held that compulsory school attendance must necessarily be supplemented by a compulsory school inspection law for effective dealing with infectious diseases. He held that it was not the place of the teacher to perform the medical inspection; the teacher can do much toward making the pupil more careful, ambitious, truthful and earnest in intellectual, moral and physical conditions, but the teacher should be well trained to understand the significance of a sound mind in a sound body. Medical inspection will do much to aid the teacher, not only by supporting his authority, but by suggestions which will assist him to maintain the health of the pupils under him at the highest possible standard. He said that an educational campaign is necessary, not only to deal with infectious diseases, but to improve those physical defects, which experience has shown to be present in a large percentage of school children, and which can be minimized, if not entirely removed. He emphasized the importance of the education of the teacher along those lines which should enable him to observe significant hygienic conditions.

Water-Gas Poisoning.

Prof. John Glaister, Glasgow, discussed the questions of the risks to health and life from the recent adoption by municipalities of carburetted gas, as a substitute for, and an admixture of the common coal gas. In Great Britain, the problems arising from the use of water gas resulted in the referring of the question to a Department Commission, and its findings in the circumstances were declared to be both reasonable and fitting. Should the adoption of carburetted water gas become general, it should be under state regulations, such as pertain in the Public Health Act to the internal drainage systems in our homes. It would be most desirable that before such gas be put in a new building, the joints and fixtures should be inspected and that in all old buildings, the existing fittings should be initially inspected and that in all buildings used for dwelling places, the power of periodical inspection by the gas authorities should be given and its exercise enforced on similar lines to those given the water companies.

International Sanitary Protection.

Dr. Peter H. Bryce, Ottawa, Chief Medical Officer of the Department of the Interior, opened this discussion by a paper on "International Coöperation in the Inspection of Emigrants and Immigrants." He referred to the problems arising from pauperism, war, commercial disaster, industrial revolutions in European countries and spoke of the continued flow of emigration to Canada. Medical inspection is most imperative and the practical coöperation which exists between England, Canada and the United States, have resulted in the development of a most desirable class of immigrants. A wise recommendation to be urged by representative medical men is that which will require specific international medical inspection in connection with immigration, and the rigid recognition and enforcement of laws regarding the influx of undesirables.

State Control of Health.

Dr. Jennie G. Drennan, St. Thomas, pleaded for a fuller recognition, by the state, of its duty toward the health of the people. She believed that in the scope of its health department should be included all hospitals, asylums and public institutions. The public should be taught how to live and if the state were as anxious to preserve health as it is to preserve peace, this desirable result would soon be attained. She deplored the tendency on the part of the public to trust its health to "patent medicines," and contended that men had been taught everything else but how to live properly. She emphasized the responsibility of the state in this direction, and urged that those having to do with the preservation of the public health should constitute an organized army of men and women made fully acquainted with their official duties by special educational courses.

Surgeon Rell M. Woodward, U. S. P. H. and M.-H. Service, Boston, outlined what had been done on the part of the United States in the medical inspection of immigrants, and described the application of rigid methods of sanitary inspection which were instituted at Rotterdam. In this inspection hot baths are given by the attendants, as the emigrants are often totally ignorant of baths and their purposes; after this, the hair of the male emigrants is cropped, and that of the female emigrants carefully combed and inspected. After a detention of five days, if no disease of any kind develops, the emigrants are allowed to proceed on their journey. Dr. Woodward believes that more attention should be given to immigrants passing through a country and that greater power should be given to the health officers of the country of destination.

Food Inspection and Supervision.

Mr. A. McGill, B.A., assistant analyst of the Inland Revenue Department, Ottawa, in a paper entitled, "Some Remarks on Food Preservatives with an Idea of Legislation in the Matter," remarked that the presence of a preservative in a product should always be announced on the label, and that the discrimination of the purchaser to protect himself by this publicity alone can not be trusted. He mentioned salt, sugar, wood smoke and alcohol as being the least injurious of the preservatives commonly used. In his report on preservatives, compiled for the dominion government, he recommended:

(a) That the use of formaldehyd or formalin, or preparations thereof, in foods or drinks, be absolutely prohibited, and that salicylic acid be not used in a greater proportion than one grain per pint in liquid food, and one grain per pound in solid food; its presence in all cases to be declared.

(b) That the use of any preservative or coloring matter whatever in milk offered for sale in the United Kingdom be constituted an offense under the Sale of Food and Drugs Acts.

(c) That the only preservative which it shall be lawful to use in cream be boric acid, or a mixture of boric acid and borax, and in the amount not exceeding 0.25 per cent., expressed as boric acid; the amount of such preservative to be notified by a label on the vessel.

(d) That the only preservative permitted to be used in butter and margarin be boric acid or mixtures of boric acid and borax, to be used in proportions not exceeding 0.5 per cent., expressed as boric acid.

(e) That in the case of all dietetic preparations intended for the use of invalids or infants chemical preservatives of all kinds be prohibited.

(f) That the use of copper salts in the so-called "greening" of preserved fruits be prohibited.

(g) That means be provided, either by the establishment of a separate court of reference or by the imposition of more direct obligation on the local government board to exercise supervision over the use of preservatives and coloring matter in foods, and to prepare schedules of such as may be considered inimical to the public health.

The author believed that the injuries produced by most preservatives is to the kidneys, and that a goodly proportion of the diseases of the kidneys may be due to this cause.

Dr. Henry L. E. Johnson, Washington, D. C., in his paper on "National Supervision and Standardization of Food," held that the question of pure food is of equal importance with that of good health and that this factor is being recognized, as is evidenced by the efforts of the hygienists, along the lines of the protection of the individual and national health. He pointed out the dangers of adulterated foods and "patent medicines" and the necessity of collecting, under a system of uniform legislation, all the duties which could possibly be assigned to boards of public health. He urged the importance of national coöperation in establishing a system of food standardization and the improvement and regulation of the conditions surrounding the preparation, production and sale of every form of food.

Sailors' Food.

Mr. William Spooner, M. R. C. S., Liverpool, pointed out that a system of inspection has done much to remove the ills connected with the rations of the sailor, but that there are still many conditions existing which need improvement. The most important fact, in his idea, was that the human organism demanded variety, and that sufficient variety was not provided as a rule. The tendency was toward the excessive use of animal food, which did not conduce to the best health conditions. The speaker believed that fresh vegetables should be placed on every ship sufficient to last for as great a portion of the voyage as possible. He discussed at length the new compulsory food scale developed along proportionate lines.

Preservatives in Food.

Prof. John Glaister, Glasgow, expressed the opinion that the use of preservatives in food is objectionable. The recognized use of certain preservatives, however, is a proof of their usefulness and he, therefore, suggested that there should be a classification of preservatives, into two classes, one of which would contain those which were harmless in operation and effect, and the other those which were harmful. He was inclined to think that a little more consideration might be paid to the effect of cold storage on food, as in many cases, meats chilled before rigor mortis has set in, putrefies very rapidly when taken out of cold storage.

(To be continued.)

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY.

Eleventh Annual Meeting, held at St. Clair, Mich., Aug. 30-Sept. 1, 1906.

(Concluded from page 886.)

Spontaneous Rupture of the Esophagus.

Dr. John O. McReynolds, Dallas, Texas, reported a case of spontaneous rupture of the esophagus, which occurred about four o'clock in the morning, the patient dying from hemorrhage in a few hours. There was no hematemesis at any time. The autopsy showed a rupture three inches long in the lower third of the esophagus, the left pleural cavity, the mediastinal space and stomach being filled with dark grumous blood. Microscopic sections showed that the esophagus was very thin-walled and that the wall had been destroyed by a process of ulceration.

The Use of Paraffin.

Dr. Secord H. Large, Cleveland, Ohio, in a paper on "The Safest Method of Using Paraffin," described the technic of subcutaneous injections in saddle-back noses, in atrophic rhinitis, and in deformities after sinus operations. He detailed the causes of failure, the high and low melting points of paraffin, and outlined the dangers of the use of this substance and how to avoid them.

Spray and Electrocautery Useless.

Dr. Edward J. Bernstein, Kalamazoo, Mich., in a paper entitled "The Comparative Uselessness of the Spray and Electrocautery for the Rhinologist," stated that in his hands he had been using the spray steadily less and less as a means of cleaning the nose, and that he had long felt that it was futile to expect cure of any nasal conditions by the spray. He stated also that he had not used the electrocautery for ten years and could think of only the smallest possible number of conditions in which it might be used in preference to the knife. He believed that much of the harm assigned to rhinology may be traced to the fact that almost every physician's office in the land is supplied with a spray apparatus, with which physicians, without regard to pathologic conditions, attempt to treat nasal affections.

Treatment of Acute Dacryocystitis.

Dr. Lee Masten Francis, Buffalo, N. Y., stated that in most cases of acute dacryocystitis, stricture of the lachrymal duct is the causal factor. The success of the treatment depends on rapid control of pus and dilatation of the stricture. It is important to avoid lacerations which may be followed by stricture. Experiments have shown that antiseptics may be driven into the lachrymal sac by the use of inunctions. Pus formation may be controlled by drainage through the canaliculi, by gentle upward massage, by ice compresses and by inunctions. The author regards the probe as invaluable, but it should not be used until the pus has nearly disappeared and the acute inflammation subsided, and then only with extreme care.

Should the Antrum be Opened in Mastoid Operation?

Dr. George F. Scott, Buffalo, N. Y., remarked that mastoid operations are performed by all sorts of physicians who always look for the antrum. After the ear has become dry, but the cells still remain affected, the antrum will be found dry also. There is no need to open it. With proper care, it is not at all difficult to select those cases which need antrectomy or the modified Schwartze operation.

Evacuation of the Tympanic Cavity.

Dr. Percy Friedenberg, New York City, claimed that aside from the operative management of such grave complications of otitic disease as sinus thrombosis and brain abscess, the most practical advance in the otology of the present day has been in the recognition of the importance of early paracentesis of the tympanum and free drainage in acute otitis, as a preventive of mastoid involvement. Any measure which will aid drainage will be welcomed. For a number of years the author has made it a routine measure to aspirate the middle ear by suction through a sterilized glass tube immediately after paracentitis. By this means a dram or more of bloody or purulent fluid will be brought out, where otherwise a much smaller quantity would be obtained. By this procedure, the incision in the tympanum may be kept from premature closure and a second paracentitis thereby may be avoided. This treatment is free from the dangers of catheterization or Pollitzeration, which increase intra-tympanic pressure and may force septic matter into the mastoid cells. Furthermore, by causing a partial vacuum, it encourages depletion of the mucosa of the middle ear and flushes out the aural cavity.

Oral Tuberculosis.

Dr. Thomas E. Carmody, Denver, described the channels of infection in tuberculosis of the mouth; primary and secondary infection and their relation to laryngeal and nasal lesions, and the influence of age, sex, occupation and personal habits. He then gave in detail the tissues most often affected with difference in lesions, and gave a description of the surgical, medical, curative and palliative treatment.

Is Laryngeal Tuberculosis a Primary Infection?

Dr. Lorenzo B. Lockhard, Denver, averred that the absence of pulmonary disease does not of itself establish the primary nature of tubercular laryngeal disease. Lymphatic involvement, especially of the tonsils and cervical glands had been proved. While the dependence of some laryngeal cases on disease of the tonsils and cervical glands had been demonstrated, a few cases had been recorded, substantiated by autopsies, in which the larynx and lungs have been found normal, and in these cases no reference has been made to the condition of the lymphatic system. There is no inherent peculiarity of the laryngeal mucosa or its secretions which should prevent it from becoming primarily infected, but as yet this occurrence has not been conclusively proved, despite the fact that tuberculosis is the most common of all laryngeal diseases.

Sarcoma of the Nose.

Dr. Robert Levy, Denver, reported a case in which the pathologic findings were verified by indisputable authority. The tumor was completely removed by intranasal operation. Recurrence did not yield to surgical measures. The development was coincident with the appearance of multiple sarcomata of the legs. After the cessation of all treatment, the nasal tumor disappeared completely, and some of the tumors of the legs also disappeared, but not all nor completely. The tumors of the leg returned and continued to grow until the patient died. At no time after the disappearance of the nasal tumor was there a return of the growth in the nose. The author then discussed the question of spontaneous disappearance of malignant growths.

Removal of the Faucial Tonsils.

Dr. Ovidus A. Griffin, Ann Arbor, Mich., stated that unanimity of opinion as regards the advisability of the complete removal of the faucial tonsils does not obtain. He gave the anatomy and physiology of the tonsils, and the indications for their removal, and stated that the extirpation should be as complete as possible. He then described an original scissors, by the use of which separation of the pillars and complete removal of the tonsils could be effected.

Eyestrain and Crime.

Dr. George M. Case, Elmira, N. Y., urged the necessity of the examination of the eyes of inmates of penal institutions and especially of reformatories and schools for incorrigibles. He stated that a large percentage of the young criminals of New York have strikingly high ocular defects. He considered eyestrain as a contributing factor in truancy in school, disinclination to work and inebriety. He believed that routine examination of the eyes of school children would do much toward the prevention of criminal tendencies and would elevate the standard of civilization, and considered that state appropriations should be made for this purpose. The managers and superintendents of institutions should be informed as to the baneful results of eyestrain in the production of crime.

Cataract Extraction.

Dr. Duff W. Greene, Dayton, Ohio, read a paper on "Cataract Extraction Within the Capsule by External Manipulation—the So-called Indian Method." The condition of the capsule often determines the amount of vision secured. Extraction within the capsule by external manipulation eliminates this and avoids secondary operation. Unfortunately, in some cases certain unknowable conditions of the zonula or of the capsule itself may defeat the endeavors to deliver the lens after this method. It is a more difficult operation than either the simple or the combined method. The section must be larger, the iridectomy broader, and the zonular attachments to the capsule must be broken up by direct and continuous pressure. The capsule itself must not be ruptured, as this is essential to the success of the method.

Cataract Extraction with Preliminary Capsulotomy.

Dr. Homer E. Smith, Norwich, N. Y., outlined the essentials of a smooth extraction, the preliminary treatment of the patient, the immediate preparation for operation, the capsulotomy done through the cornea with a knife-needle, the cornea having been dilated some hours before the extraction of the lens. He detailed the advantages of this procedure as compared with capsulotomy done subsequent to the corneal section, and described the extraction and the first dressings.

Nasal Obstruction.

Dr. Arthur E. Prince, Springfield, Ill., in his paper entitled "Some Considerations Relative to Nasal Obstruction," answered the following questions: (1) What is the cause of the prejudice against the removal of tonsils and what would overcome the prejudice? (2) What is the best method of removing hypertrophied turbinates? Is it wise to operate on both at the same time? (3) Is the return of adenoids often observed, and what is the best remedy to prevent their return? (4) What is the status of the profession with regard to the removal of adenoids, tonsils and hypertrophied portions of the turbinates at one operation? He gave a description of his methods and a summary of his results, and detailed the position, technic, anesthetic, instruments and after-treatment.

Travel Notes

(Continued from page 713.)

DISEASE AND HOSPITALS OF THE INTERIOR OF SOUTH AFRICA.

NICHOLAS SENN, M.D.
Professor of Surgery in the University of Chicago and Professor and Head of the Surgical Department of Rush Medical College.
CHICAGO.

The interior mountain plateau of South Africa has a healthful climate, and malaria, if it exist, is limited to circumscribed locations. No place along the East Coast is exempt from this disease, which prevails throughout the year, although it is much more frequent during the rainy season. Professor Koch has made the statement that in German East Africa the disease as a rule reaches its topographic limits at an altitude of 3,000 feet, and from what I have seen this rule applies to most parts of Africa. As soon as we reached this altitude we no longer saw the impress of malarial poisoning stamped on the faces of the people living on the coast, and the number of malarial patients in the hospital diminished with the increase of the altitude, being smallest in Johannesburg, which is situated nearly 6,000 feet above the level of the sea. At Victoria Falls, which has an altitude of less than 3,000 feet, malaria prevails to a considerable extent along the Zambesi River during the summer months, but the disease gradually diminishes in frequency between the river and Bulawayo, which is nearly twice as high above the level of the sea as the Victoria Falls.

Few tropical diseases have their origin either in Cape Colony or in the interior of South Africa, and the diseases encountered here resemble those met in temperate climates. The farther south I traveled from Victoria Falls the more the natives had lost their primitive-type, customs and habits, and in consequence had lost in part their resistance to some of the diseases of the Europeans, notably tuberculosis, carcinoma and appendicitis. In Cape Colony many of the natives, once black as ink, had quite a fair complexion, and the facial type had undergone decided changes toward that of the Europeans in consequence of the long-standing and free admixture of Caucasian blood. I will pass in brief review what I saw in the different hospitals as I traveled southward from Victoria Falls.

BULAWAYO MEMORIAL HOSPITAL.

This name was given to the hospital to commemorate the jubilee of Queen Victoria, and was built and opened its doors for the reception of the sick seven years ago. The hospital is a handsome brick building admirably adapted for the changeable climate of the country. It is built on the pavilion plan and is surrounded by large grounds, embellished by fine walks, trees, shrubs and flowers (see illustration). The main building, a large imposing one-story pavilion, is devoted to offices, resident surgeon's quarters and European patients. The capacity of the hospital is 120 beds, of which about one-half are in the two detached rear pavilions for the natives.

The European part has a number of well-furnished pleasant private rooms, for which the patients pay $1.50 a day. A number of larger rooms contain two and three beds, for which a smaller charge is made. Patients in the large wards pay according to their means. Most of the blacks are charity patients, but for some of these their employers pay a small sum. Henry Curtis, B.S. and M.D. (Lond.), F.R.C.S., is the resident surgeon. He does all the operative work, and his results have been exceptionally good, so much so that the surgical material has increased considerably from year to year during his term of service. He is a fine young man with superior attainments, and has kept pace with modern medical and surgical literature, although he has been isolated from medical centers for a number of years. The patients are nursed by three English Sisters and 13 pupil nurses. I was particularly impressed with the neat and clean conditions of the two wards for natives, and with the care given their patients by the Sisters and nurses. The operating room is small, but fairly well equipped for aseptic work. The institution has a Roentgen apparatus, the first one I saw in Africa, which is in charge of the resident surgeon.

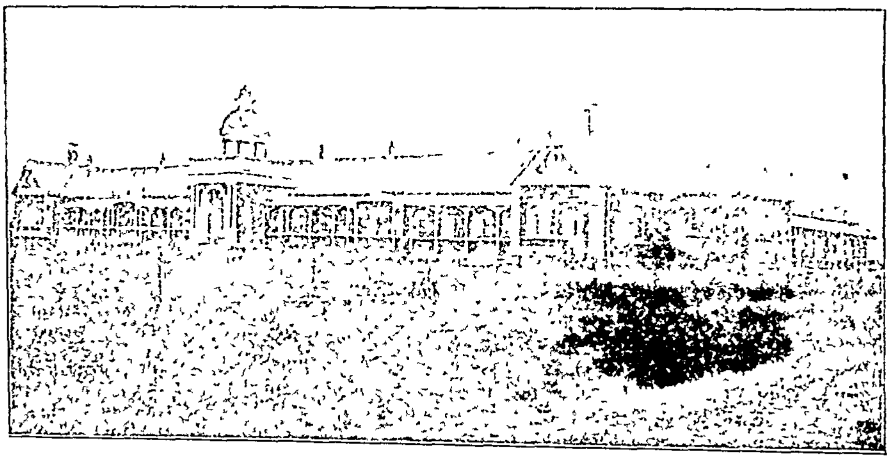
In this hospital I first learned of the effects of civilization on the blacks, in causing a growing susceptibility to some of the diseases to which the savages appear to be almost immune. I refer particularly to carcinoma, appendicitis and tuberculosis of bones, joints and lymphatic glands. I saw none of these diseases in the blacks in the hospitals of the East Coast. Dr. Curtis has collected 12 cases of malignant disease in negroes, and is preparing a report of these for the medical press. In the hospital report for 1905 I find mention of two cases of sarcoma of bone occurring in natives; three cases of tubercular glands, and four cases of tuberculosis of bone, in one of which the disease involved the left humerus and right scapula, in two the vertebræ and in one the pubic bone. One case of appendicitis in the native is reported in which an abscess had formed. The patient was operated on, but died a few days later from pneumonia and cardiac failure. In the cases of glandular tuberculosis the disease implicated the inframaxillary glands in one case, the axillary in another, and in the third the crural glands were affected. During the year referred to, the hospital took care of 1,261 patients—722 whites and 539 blacks—and the average number of in-patients was 54. At the time of my visit not more than half the beds were occupied.

The demand on the hospital space is always heaviest during the rainy season, when the malarial patients, many coming from a distance, form the bulk of the inmates. The salubrity of the high mountain plateau of South Africa has become almost proverbial in that country. During the year, 469 cases of malaria and one of black-water fever were treated in the hospital, but in many of the cases the disease did not originate in Bulawayo or anywhere near it, as many of these patients came from localities where malaria is endemic. It is interesting to know that of the 469 cases of malaria only 128 of the patients were blacks, and that of the 19 cases of black-water fever all were whites with the exception of one, a colored boy from the Cape. Only 17 patients with typhoid fever entered the hospital during the year, and of these, 5 died, all of whom, with one exception, were whites. Of ten cases of pulmonary tuberculosis, six were in whites and four in blacks. Influenza is credited with only three cases, two whites and one negro; acute and subacute rheumatism with 31 cases, 10 whites and 21 blacks; pneumonia with 66 cases, and only two deaths; 17 whites and 49 blacks. Of 35 cases of scorbutus, 33 were blacks, and of these, 5 died; of the two whites, one died. None of the figures in the statistics is large, the diseases enumerated covering almost the entire nomenclature, and the absence of tropical diseases and the small number of acute gastrointestinal diseases is noteworthy, and the best possible evidence that Bulawayo is not a good place for many doctors.

The small number of injuries treated in the hospital also attracts attention. Only five amputations for injuries were performed during the year. Among the fractures enumerated were three of the skull, two of the ribs, four of the clavicle, one of the humerus, one of the radius and five of the tibia and fibula, all compound. Of the 134 operations performed, 48 were on whites and 86 on blacks. The hospital receives an annual government grant of $18,000, which is a material aid in defraying the necessary expenses. Half the cost of free native patients is also borne by the government, which amounted during the year 1905 to over $6,000. The entire expenses of the hospital amounted to about $65,820.

CARNARVON HOSPITAL, KIMBERLEY.

Kimberley is the most famous diamond city of the world, and its population of about 75,000 depends largely on the brilliant gems taken from its five mines. It has only one general hospital, named after a former governor. This was built soon after the discovery of the mines, twenty-five years ago, and has been enlarged since that time to meet the constantly increasing demands. Like all South African hospitals, it is constructed on the cottage plan, the building material of the one-story pavilions being brick and the roof corrugated iron. It can accommodate 200 patients. The two large wards for the blacks are detached from the remaining buildings, as well as the new hospital for white children. Patients who can afford to pay are charged from 25 cents to $7.50 a day, according to accommodations. A large number of plainly furnished, comfortable rooms are the main source of income. The only government support the hospital receives is the hospital head tax of 25 cents a week imposed on all adult male natives. The large grounds, the broad verandas around each pavilion and the grate fires in the wards impart to the hospital an aspect of home comfort. At the time of my visit a biting cold wave from the south swept the treeless plains unmercifully and the open grate fires looked particularly attractive.



Bulawayo Hospital.

Two resident surgeons live on the premises in separate buildings and devote their whole time and attention to the care of the inmates. The senior resident surgeon is permitted to do consulting work outside of the hospital, but the junior's income is limited exclusively to his small salary. Nine English Sisters and 50 nurses and probationers have charge of the nursing. The training school for nurses in connection with the hospital is in a flourishing condition. A three years' course is compulsory. The teaching is done by the Sisters and regular lectures are given by the medical staff. The nurses' home is a new separate modern building. Cleanliness and good order prevailed throughout the institution, and the blacks seemed to be well cared for. All the blacks who die here are subjected to postmortem examination, and the permission of the natives is never asked. In the children's ward I saw a child on whom tracheotomy had recently been performed for diphtheritic laryngitis and the little patient was well on the way to recovery. Intubation is not regarded with favor in this part of Africa, and when surgery has to be resorted to in cases of laryngeal stenosis, tracheotomy is the operation of choice. A laparotomy for pelvic inflammation was in progress in the plain, large, well-lighted operating room at the time of our visit. Operating gowns, masks and gloves are not often, if ever, seen in the operating rooms of the South African hospitals. The surgeons roll their sleeves up to the elbows, cleanse and disinfect their hands, put on aprons and then go to work. Several cases of injury from dynamite explosions and a number of fractures made up the bulk of the surgical material.

COMPOUND HOSPITALS.

By a compound is meant the enclosure of a mine in which the miners, usually Kaffirs, are confined as long as they are in the service of the company, which on an average is six months. No one can enter these compounds without special permission, and the miners are not permitted to leave the premises. Each of the five diamond mines employs from 2,000 to 2,500 blacks. The large square in which they live is surrounded by a wall. The sleeping places, butcher shop, stores and hospital are built all around against the wall, and in the large open space the blacks cook, eat, wash, smoke and play. I saw here a group of blacks who were smoking hemp, passing a large pipe from one to the other. Each of them took a large draught, retained the smoke for some time in the distended mouth, and then allowed it slowly to escape. At least two who were enjoying this vice, showed plain manifestations of intoxication.

Each compound has its own hospital and doctor. The building is constructed of corrugated iron, and has accommodation for about eighty patients. A dispensary and small operating room are to be found in each of these hospitals. The nursing is done by male attendants, but in one of the compounds a trained female nurse of mature age was at the head of the nursing staff, and it was in this hospital that the wards and bedding were cleanest.

The prevailing diseases among the miners are bronchitis, pneumonia and scurvy. Scurvy is very common and, as the physician of one of the compounds assured me, is due to the lack of vegetable food, which is very expensive here, and which the blacks refuse to buy in sufficient quantity on account of the high price, as they are anxious to save all the money they can to enable them to return to their homes as soon as possible. The most common injuries are burns and wounds from dynamite explosions and fractures. Among the interesting cases I saw here was a negro, the subject of multiple large keloids and an albino Kaffir. The man was about 30 years of age, with fair complexion, red curly hair and the characteristic eyes of the albino. I was informed that the average mortality from pneumonia in these compound hospitals is not less than 25 per cent. I saw and examined a number of cases during the acute stage of the disease, and in each of them the viscid rust-colored sputum was present.

It is not so very easy for the blacks to get into one of these compounds, as they have to undergo a thorough physical examination by a physician, but there is more ceremony connected with their getting out. Stealing of diamonds by the miners is an old trick and has cost the companies millions of dollars. All kinds of devices have been invented and practiced by the blacks to enrich themselves by stealing now and then a diamond which they find. To encourage honesty, the company pays each miner 10 per cent. of the value of the stones he finds, provided he delivers them at once to the manager. Notwithstanding this inducement, thefts are by no means rare even now with all possible precautions to guard against them. Some of the compounds are roofed in with wire netting to avoid all possibility of communication between the natives and the outsiders. The shrewd blacks will hide away diamonds in all avenues of their bodies whence they can be removed after they have left the compound. Against this method of pilfering the company now has instituted and enforces a measure well calculated to do away with this practice. When a black miner signifies his intention to leave the compound, he is put in a separate place and under guard, with others who are about to leave, and is subjected to repeated examinations for one week. Both of his hands are confined in stout leather mittens fastened with a lock at the wrists. This muffling of both hands prevents the temporary prisoner from grasping and disposing of any diamonds hidden in any part of his body, or the body of any of his companions. Each man is given a brisk dose of castor oil, the discharges are examined, and if at the end of a week no diamonds are found, he is given his liberty. In one compound I counted twenty blacks, lying side by side in a room, who were under observation prior to their departure. The physical condition of the men who leave the mines, after working on an average for six months, is much better than at the time of their entrance, as I had abundant opportunity to observe.

(To be continued.)

State Boards of Registration

COMING EXAMINATIONS.

OKLAHOMA Board of Medical Examiners, Guthrie, September 25. Secretary, J. W. Baker, Enid.

NEW YORK Boards of Medical Examiners, Albany, September 25-28. Chief of Examining Division. Charles F. Wheelock, Albany.

UTAH State Board of Medical Examiners, Salt Lake City, October 1. Secretary, R. W. Fisher, Salt Lake City.

ARIZONA Board of Medical Examiners, Phoenix, October 1-2. Secretary, Ancil Martin, Phoenix.

COLORADO State Board of Medical Examiners, Denver, October 2. Secretary, S. D. Van Meter, Denver.

IDAHO State Board of Medical Examiners, Lewiston, October 2. Secretary, J. L. Conant, Jr., Genesee.

MONTANA Board of Medical Examiners, Senate Chamber, The Capitol, Helena, October 2. Secretary, Wm. C. Riddell, Helena.

MINNESOTA State Board of Medical Examiners, Old Capitol Building, St. Paul, October 2-4. Secretary, W. S. Fullerton, St. Paul.

NORTH DAKOTA State Board of Medical Examiners, Grand Forks, October 2-4. Secretary, H. M. Wheeler, Grand Forks.

RHODE ISLAND State Board of Health, Room 313, State House, Providence, October 4-5. Secretary, Gardner T. Swarts, Providence.

GEORGIA Board of Medical Examiners (Regular), Capitol, Atlanta, October 9. Secretary, E. R. Anthony, Griffin.

ARKANSAS State Medical Examining Board, Little Rock, October 9. Secretary, J. P. Runyan, Little Rock.

KANSAS State Board of Medical Registration and Examination, State House, Topeka, October 9. Secretary, F. P. Hatfield, Grenola.

MICHIGAN State Board of Registration in Medicine, Lansing, October 9. Secretary, B. D. Harison, Detroit.

MISSISSIPPI State Board of Health, The Capitol, October 9. Secretary, J. F. Hunter, Jackson.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, October 11. Secretary, Geo. C. Ober, Washington.

NEW JERSEY State Board of Medical Examiners, Trenton, October 16-17. Secretary, J. W. Bennett, Long Branch.

TEXAS State Board of Medical Examiners, Houston, October 16-18. Secretary, T. T. Jackson, San Antonia.

FLORIDA Board of Medical Examiners (Regular), Jacksonville, October 17-18. Secretary, J. D. Fernandez, Jacksonville.

ILLINOIS State Board of Health, Great Northern Hotel, Chicago, October 17-19. Secretary, J. A. Egan, Springfield.

LOUISIANA State Board of Medical Examiners, New Orleans, October 19-20. Secretary, F. A. Larue, New Orleans.

INDIANA Board of Medical Registration and Examination, Indianapolis, October 23-25. Secretary, W. T. Gott, Indianapolis.

Kentucky July Reports.—Dr. J. N. McCormack, Secretary of the State Board of Health of Kentucky reports the following examinations: At the examination held at Louisville, July, 1906, the number of subjects examined in was 13; total number of questions asked, 120; percentage required to pass, 70, not less than 60 in any one branch. The total number of candidates examined was 17, of whom 11 passed, including 2 osteopaths, and 6 failed, including 3 osteopaths and 1 graduate in optics. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent
Hospital Coll. of Med., Louisville	(1906)	72, 79
University of Louisville	(1906)	76
St. Louis Univ. (Marion-Sims-Beaumont Med. Coll)	(1906)	76
Barnes Med. Coll	(1906)	74
Medical Coll. of Ohio	(1902) 82; (1906)	78
University of Pennsylvania	(1905)	85
University of Tennessee	(1906)	70

FAILED.

Hosp. Coll. of Med., Louisville	(1903)	65
Univ. of Tennessee	(1905)	55

At the meeting held July 16, 1906, the following were granted licenses to practice medicine without examination:

	Year Grad.	Total
Hosp. Coll. of Medicine, Louisville	(1896) 1; (1906)	40, 41
University of Louisville	(1887) 1; (1894)	1, 2
Kentucky School of Med	(1888) 1; (1906)	6, 7
Louisville Med. Coll	(1906)	1

At the meeting held July 22, 1906, the following were granted licenses to practice medicine without examination:

Louisville Med. Coll	(1906)	4
Kentucky School of Med	(1906)	2
University of Louisville	(1899)	1

New Louisiana Officers.—We learn from Dr. Felix A. Larue, secretary of the Louisiana State Board of Medical Examiners, that on and after Oct. 1, 1906, the office of the board will be Room 502, Tulane-Newcomb Building, 211 Camp Street, New Orleans.

New Nebraska Rules.—Dr. George H. Brash, secretary of the Nebraska State Board of Health, sends us the following resolutions which were adopted and approved by that board, Aug. 8, 1906:

Resolved, That after July 1, 1906, no one shall be allowed to practice medicine or osteopathy until a certificate has been issued by the Nebraska State Board of Health.

Resolved, That after July 1, 1906, no one shall be granted a certificate on reciprocity unless the applicant has been in active practice in the state, by whose board he is endorsed, for at least one year immediately preceding such endorsement.

West Virginia July Report.—Dr. H. A. Barbee, Secretary of the West Virgina State Board of Health, reports the oral and written examination held at Charleston, July 10-12, 1906. The number of subjects examined in was 9; total number of questions asked, 120; percentage required to pass, 80. The total number of candidates examined was 79, of whom 52 passed and 27 failed, including 15 non-graduates. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
George Washington University	(1904)	86
American Coll. of Med. and Surg., Chicago	(1906)	82
Drake University	(1905)	82
Louisville Med. Coll.	(1906)	97
Kentucky University	(1906)	82, 86
University of Louisville	(1906)	87
Hospital Coll. of Med.	(1904)	87

*Merged with Starling Medical College in 1892.

The following questions were asked:

PRACTICE OF MEDICINE (REGULAR AND HOMEOPATHIC).

1. Describe the tongue in typhoid fever; chronic gastric catarrh: billousness and scarlet fever. 2. Cirrhosis of the liver: give symptoms and causes. 3. Give normal dimensions of the liver in midaxillary and mammary line. 4. What is the pulse rate at birth, at five, ten, fifteen and twenty years? 5. What is arteriosclerosis and what are the symptoms? 6. Where is the apex beat of the heart felt? Where are the various murmurs heard? What causes the heart sounds? 7. What is fever? What is the normal temperature? Name a disease in which fever occurs. What is hyperpyrexia? What is a subnormal temperature? How control fever? 8. Vomiting: Describe the cause, mechanism and general therapy. 9. Physical diagnosis: (1) What is vocal frematus? (2) What is vocal resonance? (3) What is a mucous râle? (4) What is a crepitant râle? (5) What is a friction murmur? 10. Give differential diagnosis between smallpox, chicken pox and pustular syphiloderm.

MATERIA MEDICA (HOMEOPATHIC).

1. Give indications for sepia in female trouble. Compare with pulsatilla. 2. In constipation, with no movement of bowels without cathartics or enema, what drugs are called for? Give indications. 3. What remedies are called for in dysentery. Give characteristics. 4. Give indications for rhus tox in typhoid. Compare with similar acting drugs. 5. Differentiate between cuprum-arsen. and merc. corr., in bowel trouble. 6. Mention four polychrests. Give characteristics of each. 7. Mention three remedies having a pathogenesis of green diarrhea and give characteristics. 8. Give indications for three remedies curative in nasal catarrh. 9. Differentiate gelsemium and natrum muriaticum in intermittent fever. 10. Give the therapeutic individuality of sulphur and phosphorus.

MATERIA MEDICA AND THERAPEUTICS (REGULAR).

1. Define materia medica and therapeutics. What is the difference between empirical and rational therapeutics? 2. Name four ways by which medicine may be introduced into the circulation. 3. Give a rule for calculating doses of medicine for children. 4. Name three drugs excreted by the mammary glands and which may affect the nursing infant. 5. From what source is ergot derived, and what is its most important physiologic action?. 6. What is the difference between an abstract and an extract? What are expectorants, diaphoretics, diuretics? How do they act? 7. What is normal saline solution, how administered and in what conditions used? 8. Dose of salol. How disposed of in intestines? How eliminated? Symptoms of overdose. 9. Name one hydragogue cathartic, one intestinal antiseptic, one hypnotic, one antiseptic, give dose of each. 10. What are alkaloids? Name six important ones with dose.

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC).

1. Apocynum: Indications and uses. 2. Apis: Indications and uses. 3. Aralia: Indications and uses. 4. Belladonna: Indications and uses. 5. Cactus: Indications and uses. 6. Passiflora: Indications and uses. 7. Libradol: Indications and mode of application 8. Aconite: Indications and uses. 9. Ipecac: Indications and uses. 10. Echinacia: Indications and uses.

PRACTICE OF MEDICINE AND PATHOLOGY (ECLECTIC).

1. Typhoid fever: Give etiology, symptoms, diagnosis and treatment. 2. Diphtheria: Give etiology, symptoms, diagnosis and treatment. 3. Give the early diagnosis of tuberculosis of the lungs and the treatment. 4. Appendicitis: Give medical treatment. 5. Lobar pneumonia: Diagnosis and treatment. 6. Smallpox: Give briefly the management and treatment. 7. Scarlet fever: State briefly the care and treatment until dismissed. 8. Rubeola: Give symptoms, diagnosis and treatment. 9. Malarial fever: Give etiology, symptoms, diagnosis and treatment. 10. Cholera infantum: Give symptoms, diagnosis and treatment.

PHYSIOLOGY.

1. Give reaction of the following fluids: Blood, milk, gastric juice, pancreatic juice, saliva, urine and perspiration. 2. In what tissues of the body is lime phosphate most found and its absence constitutes what diseases? 3. From what source are starch, glycogen and sugar derived? 4. What disturbances of digestion result from absence of bile? 5. What is the change in the air breathed, before and after inhalation? 6. Define sensitive nerve, motor nerve, mixed nerve. Give example of each. 7. What are the function and distribution of the fifth pair of nerves? 8. What is meant by nutrition? Define proximate principle. Gixe example. 9. Give composition and functions of the blood. 10. What is fat and how and where digested in the alimentary canal?

ANATOMY.

1. Mention the sutures at the vertex of the skull and state what bones they unite. 2. Mention any one muscle which moves the humerus (1) forward, (2) backward, (3) inward. 3. Describe the renal circulation. 4. Name the bones of the head. 5. Name the principal lobes of the brain and fissures dividing them. 6. Minutely describe the relations of the peritoneum to the bladder. 7. Describe the inguinal canal. 8. Locate and briefly describe the gall bladder. 9. Describe the female urethra as to (1) location, (2) dimensions, (3) structure. 10. What is contained in the right hypochondriac region?

CHEMISTRY.

1. Give names and formulæ of five acids used in medicine. 2. What is "rough on rats?" What is the antidote? 3. What is carbolic acid, physical and chemical properties, antidote? 4. What is arsenic, chemical properties, antidotes? How would you detect it in a solution? 5. Give test for formaldehyd in milk. 6. What are the constituents of normal urine? 7. Name all the different tests for albumin. 8. Name all the tests for sugar. Give formula for Fehling's solution. 9. What are carbohydrates? Name four. 10. What is an incompatible? Name three. What is an insoluble? Name three.

HYGIENE.

1. What is the difference between permanent and removable hardness of water? 2. What is the difference between contagion and infection? 3. Define the terms epidemic, pandemic and endemic. Name a disease of each. 4. How much cubic air space should be allowed each person in a sleeping room? Why? 5. What is the difference between antiseptics, disinfectants and deodorants? 6. Name five of the best disinfectants and explain their action and method of use. 7. What conditions of climate would you recommend for tuberculous patients? Does such a location exist in West Virginia? Explain. What is the best method for preventing the spread of tuberculosis from a sanitary standpoint? 8. How would you prevent the spread of the following: Typhoid fever, diphtheria, scarlet fever and measles? 9. Should a person have gas lights, oil lamps, candles or growing plants in a sleeping room? 10. What is ventilation? Explain the difference between natural and artificial.

OBSTETRICS AND GYNECOLOGY.

1. What bones and ligaments form the obstetric pelvis? 2. Name all the female organs of generation. 3. Describe the stages of formation of embryo and its membranes. 4. Describe the fetal circulation. 5. Give the steps of a normal labor in a primipara? Multipara? 6. A patient with babe six weeks old calls you, she is suffering with pain and dragging in lower abdomen, is very tender, temper-

ature 102.5, a profuse discharge from vagina. On examination you find the uterus measuring five inches and lacerated on the left. Patient is a very sick woman, generally, womb soft and boggy. Treat. 7. Describe a case of placenta prævia centralis, give treatment. 8. Define eclampsia, give symptoms and treatment. What is the prognosis of eclampsia as to mother and child? 9. What constitutes the "bag of water?" What is its functions or office? Would you rupture? 10. Tell how to handle a case of abortion at second or third month.

BACTERIOLOGY.

1. How do you classify bacteria? Name three divisions. 2. What are the products of bacteria? 3. Do bacteria develop spontaneously? Does body temperature affect them. 4. How do micrococci grow? 5. Define sterilization. How obtained? 6. What is an antiseptic? The most effective. 7. Which contains the greatest number of bacteria, river water or ground water and why? 8. What methods are used to free drinking water from bacterial danger? 9. What theory has been brought forward to explain the resisting power of the human body against pathogenic invaders? 10. What factors influence the development of various pathogenic bacteria in the body?

SURGERY.

1. Inflammation: Define, name two common varieties. 2. What constitutes an exotosis, a neoplasm? What is a gumma? Cause, most frequent site and treatment. 3. Define, divide and treat hemorrhage. 4. Describe amputation at middle third of leg, naming important structures severed. Complete operation. 5. Aneurism: Define, give varieties and treatment. 6. Otitis: Define, classify, give cause and treatment. 7. Fracture: Define, classify and give symptoms. Describe and treat a Colles' fracture. 9. Dislocation: Define and classify. 10. Reduce a backward dislocation of humerus at shoulder.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Eczema.

In the treatment of eczema of the female genitals the following combination is recommended by von Schlen in the *Amer. Year Book of Med. and Surgery:*

℞.	Ichthyoli	gr. xv	1
	Pulv. amyli		
	Ung. zinci oxidi, āā	ʒiii	12
	Lanolini	ʒvi	24

M. Ft. unguentum. Sig.: Apply locally to the affected parts.

In dry eczema of the scalp, neck and external genitals the following combination is recommended, using coal tar instead of wood tar:

℞.	Picis carbonis (coal tar)	ʒiss	6
	Alcoholis (95 per cent.)	ʒi	4
	Spts. etheris sulphurici	ʒss	2

M. Sig.: Apply locally with a brush.

In the treatment of professional eczema of the hands the following combinations are advised:

℞.	Zinci oxidi	℥ii	60
	Pulv. cretæ		
	Lotio plumbi		
	Olei lini, āā	ʒss	15

M. Ft. mistura. Sig.: Apply locally to the affected parts. Or:

℞.	Zinci oxidi		
	Sulphuris sublim.		
	Cretal prep.		
	Olei lini, āā	℥ss	15
	Aquæ calcis, āā	℥i	30

M. Sig.: Apply locally.

The foregoing combinations are of value in the milder forms of eczema. Previous to going to bed the patient should be instructed to cleanse his hands carefully and nails with soft soap if the eczema be dry, or with weak soapsuds if the eczema is moist, followed by thoroughly drying the hands and applying the ointment, and at the same time rubbing the hands until the ointment is completely absorbed. The hands should then be covered with gutta percha tissue, thin strips being wrapped around each finger. The whole hand should then be covered with wool-like mittens. The following morning the dressing should be removed, the hands cleansed and a small amount of the ointment again rubbed in for the day. After recovery is almost complete there will remain a few patches, which should be touched up with chrysarobin stick made up as follows:

℞.	Chrysarobin	ʒii	8
	Lanolini	℥iss	45
	Ceræ albæ	ʒvi	24

M. Melt and pour into glass tubes and allow to cool. Sig.: Touch the affected areas two or three times a day.

The hands of those patients who are required to handle lime, plaster and cement must be protected during their work. This may be done by instructing the patient to rub his hands, before beginning his work, with tar diluted with castor oil and alcohol, as this combination is not only palliative and curative, but neutralizes the action of the lime.

In some cases the following combination is recommended to stimulate the corneous layer of the skin:

℞.	Zinci oxidi	gr. xv	1
	Lanolini		
	Resorcin, āā	ʒiiss	10
	Cretæ prep	ʒss	2

M. Ft. unguentum. Sig.: Apply locally.

In the treatment of chronic palmar eczema the following combinations are recommended by the *Medical Bulletin:*

℞.	Olei cadini		
	Olei olivæ, āā	℥ii	60

M. Sig.: Apply locally twice a day. And:

℞.	Acidi salicylici	ʒi	4
	Camphoræ		
	Chloralis hydratis, āā	gr. xv	1
	Sulphuris precip	ʒi	4
	Adipis benzoinatis, q. s. ad	℥i	30

M. Ft. unguentum. Sig.: Apply locally after applying the oils as given.

Intestinal Dyspepsia.

Diarrhea and intestinal indigestion, according to Hemmeter in *Pract. Med. Series,* may be due to failure of gastric digestion, abnormal fermentative changes in the stomach, imperfect function of the pancreas, fermentation or putrefaction in the intestine.

The treatment is: 1. Dietetic, avoiding alcohol, tea, coffee and tobacco, and regulating the diet by excluding those articles which pass the intestines undigested or else give them in very small quantities and in a finely divided state. The experience of the patients is often a good guide. 2. In the treatment of constipation present the practitioner should decide whether it is due to spasm or atony, and in many cases this may have to be determined by therapeutic tests.

[In spastic constipation the patient has colicky pains, especially after eating sour foods, and when he has gone to stool there is a feeling of incomplete evacuation, the caliber of the stool is small, ribbon-shaped, as differentiated from the large caliber of the stool in atonic constipation.]

Care should be taken in the last meal of the day, as a heavy supper often produces a restless night. The treatment, according to Hemmeter, of the general neurasthenia should be electrotherapy, hydrotherapy, massage and baths.

Insomnia may be corrected by simply flushing out the colon. Hypnotics should be avoided if possible. As intestinal antiseptics in these cases the author recommends bismuth salicylate, subgallate, betanaphthol bismuth, thymol, menthol, resorcin and salol.

For putrefactive diarrhea with abdominal pain the following combination is recommended:

℞.	Bismuthi subgal.	ʒii	8	
	Salve	gr. xxiv	1	65
	Ext. opii (denarcotized)	gr. iii		20

M. Ft. capsulæ No. xii. Sig.: One capsule before meals.

For the anexoria the following combination:

℞.	Strych. sulph.	gr. 1/3		02
	Acidi hydrochlor. dil	℥ss	15	
	Ext. condurango flu	f℥iss	45	
	Elix. gentianæ	℥vi	180	

M. Sig.: One tablespoonful in two ounces of water one-half hour before meals, taken through a glass tube. Or:

℞.	Tinct. nucis vom	ʒiiss	10
	Tinct. card. co	℥ii	60
	Tinct. gent. co	℥vi	180

M. Sig.: One tablespoonful three times a day before meals in a small amount of water.

Or, according to Boas, the following:

℞.	Ext. nucis vom	gr. vi		40
	Bismuthi subcarb.	ʒiiss	10	

M. Ft. chartulæ No. xx. Sig.: One before each meal.

Menche recommends the following combination:

℞.	Resorcin resublim.	gr. lxxv	5	
	Tincturæ rhei	℥ss	15	
	Elix. simplicis, q. s. ad	℥iii	90	

M. Sig.: One tablespoonful twice a day before meals. Or:

℞.	Resorcin resublim	gr. lxxv	5	
	Bismuthi salicylatis			
	Pulv. rhei			
	Sodii sulphatis, āā	ʒiiss	10	
	Sacch. lactis	ʒiiiss	14	

M. Sig.: One teaspoonful before each meal.

When fermentation is present with anorexia the following formula after Ewald is advised:

℞.	Tinct. nucis vom	ʒvi	24	
	Resorcin sublim	gr. lxxv	5	
	Elix. simplicis	ʒiii	12	

M. Sig.: Ten to fifteen drops every two hours in a small amount of water. Or:

℞.	Ext. condurango flu	fʒv	20	
	Resorcin sublim	ʒi	4	

M. Sig.: Thirty drops four times a day in water.

When anemia is present with the gastrointestinal symptoms the following combination is recommended:

℞.	Quin. sulph	gr. xviii	1	20
	Strych. sulph	gr. 1/3		02
	Ferri sulph	gr. xii		75
	Acidi arsenosi	gr. 1/5		014

M. Ft. pil. No. xii. Sig.: One pill three times a day.

Tongue and Mouth in Typhoid Fever.

In considering the care of the tongue and the mouth in typhoid fever Shoemaker states that some of the gastrointestinal symptoms may be avoided. The mouth should be thoroughly cleansed after each feeding with an antispetic solution similar to the following combination:

℞.	Creosoti (beechwood)	m. xv	1	
	Aq. eucalypti	f℥vi	180	

M. Sig.: To be applied with a swab of absorbent cotton after each feeding.

When the lips become dry as well as the tongue the following application is recommended:

℞.	Acidi citrici	ʒv	20	
	Syrupi limonis	f℥i	30	
	Aquæ q. s. ad	f℥viii	240	

M. To be used as a mouth wash, diluted as necessary.

When the tongue becomes dry and brown the internal administration of turpentine will often be effective, given in the form of the official emulsion of the new Pharmacopeia, or as follows:

℞.	Olei terebinthinæ	ʒiv	15	
	Olei amygdalæ exp	m. lxxv	5	
	Syrupi	ʒvi	24	
	Pulv. acaciæ	℥ss	15	
	Aquæ q. s. ad	℥iiiss	100	

M. Sig.: One to two teaspoonfuls three or four times a day.

If there is any contraindication to its use, such as nausea or some kidney involvement, the author recommends that dilute nitric acid be given in five-minim doses (.30), well diluted in water, three times a day after food.

Medicolegal

Evidence in Action by Physician Against Administrator.

The Supreme Court of Colorado holds, in Temple vs. Magruder, a case where the latter-named party sought to recover against an administrator a judgment on a claim for medical services, that the physician's account book must be deemed a book of original entry, and would have been admissible in evidence had the preliminary proof required by the statute been made. But it holds that it was clearly error to permit the physician to testify in the case, because of the statute providing that "no party to any civil action, suit or proceeding, or person directly interested in the event thereof, shall be allowed to testify therein, of his own motion, or in his own behalf, . . . when any adverse party sues or defends as the . . . executor or administrator . . . of any deceased person . . . unless when called as a witness by such adverse party so suing or defending." By the plain and positive provision of this statute, the physician, the court says, was incompetent to testify in this case of his own motion, and over the objection of the administrator, on any matter, or at all.

Opinions of Unprofessional Observers as to Sanity.

The Supreme Court of Kansas says, in the case of Kempf vs. Koppa, that an unprofessional observer is competent to form a judgment and express an opinion on the sanity or insanity of one he knows. A fundamental qualification is that the witness shall have had adequate opportunities of observation of the conduct, declarations and appearance of the person whose sanity is in question. The weight and force of the testimony will depend on the extent of the opportunity, as well as the power and habits of observation possessed by the witness, and a consideration of all the circumstances under which the opinion was formed. The courts do not undertake to lay down a definite rule as to how closely the witness must have observed the person whose sanity is the subject of inquiry in order to be qualified as a witness, as even a casual observer may discover mental manifestations that would make his testimony valuable. Whether there is a fair basis for an opinion by a witness must be left largely to the trial court, and the jury, taking note of the opportunity and powers of observation of the witness, must then decide what weight and effect shall be given to his opinion.

Nature of State Board of Health and Its Acts—Powers—Revocation of Certificate.

The Supreme Court of Missouri says that in the case of State, on the relation of McAnally vs. Goodier and others, the relator (McAnally) asked for a writ of prohibition to prevent the State Board of Health proceeding in an investigation of charges of alleged improper conduct and revoking a certificate to practice medicine and surgery issued to him in 1883. Under the act of 1883 he was not required to have a certificate from the State Board of Health to entitle him to practice medicine, because he had been practicing for a period more than five years before the law was enacted, and he maintained that the board had no right to revoke the certificate issued to him, even if it should find after investigation that he was morally unworthy to exercise the high calling, because he said that the board had no right to issue it in the first place. But a complaint of that kind does not make a very persuasive appeal for a writ which, after all, is within the sound discretion of the court to issue or refuse independent of strict technicality, as the very right and justice of the case require. The certificate implied not only that the holder is learned in the science, but that he is, from a moral or ethical standpoint, worthy to be trusted. In this case, if the board, on investigation, should find the relator guilty of the charges preferred, the utmost it could do would be to cancel the certificate that it had itself issued, leaving the relator in full possession of what he said the law gave him independent of the board—that is, the right to practice medicine on his own merits; but it would not leave him armed with his certificate of good character from the State Board of Health. The relator had no right to hold that certificate if he was unworthy of the confidence it invited.

The relator complained that the board was going to try him without exercising compulsory process to bring before it the witnesses he needed for his defense. But the State Board of Health is not a court—is not a judicial tribunal. It can issue no writ. It can try no case—render no judgment. It is merely a governmental agency, exercising ministerial functions. It may investigate and satisfy itself from such sources of information as may be attainable as to the truth or falsity of charges of misconduct against one holding one of its certificates, but its investigation does not take on the form or *character of a judicial trial.* The law does not contemplate that the technical rule of evidence applicable to a judicial trial will be strictly followed, or that compulsory attendance of witnesses will be made. It contemplates that a plain, honest, common-sense investigation shall be made, with good faith and as thorough as may be with the light of such evidence on either side as is obtainable without process and with the means at hand, much like the investigation that fair-minded, intelligent men would make in their own business concerning the alleged misconduct of one of their employés, with this difference only, that the board can not revoke the license except for cause and after the accused has had an opportunity to be heard.

The statute says the board may refuse to issue the certificate, or may revoke it after it has been issued, if the man is unworthy. This implies that the board may have some information of misconduct of an applicant which would justify a refusal to issue the certificate, or, after the certificate is issued, that would justify its recall, and in either case the board is authorized to act, "after giving the accused an opportunity to be heard." Those are the only words that suggest a trial, and they fall far short of a judicial trial. To guard and protect the health and welfare of its people the state must have its ministerial agents or officers and intrust them with power. If every administrative act that looks to the enforcement of the law should be required to be reduced to the compass of a lawsuit and be put into effect only after a court had at the end of a formal trial stamped its judgment on it, the government would make slow progress. There must be trust reposed somewhere and the power to execute the law. The General Assembly has taken great care to secure trustworthy men to perform the duties that are devolved on the State Board of Health. The duties of the board are of an administrative or ministerial character, and, therefore, as long as its acts are within the scope of the exercise of a reasonable discretion it is free to act. If perchance, through a misunderstanding of the law, the board should refuse to perform a given duty, the writ of mandamus will right the wrong, but the writ of prohibition does not go against such a body. It goes only against a court or a tribunal exercising judicial functions.

In other words, the court holds in this case that the state board of health is not a judicial body; that it has the power to revoke a license or certificate issued by it if, after investigation, in which the licensee is afforded an opportunity to be heard, it is satisfied that he has been guilty of unprofessional or dishonorable conduct; and that, in conducting such investigation (or "trial," if that term is preferred), it is not assuming to exercise a judicial function. Therefore a writ of prohibition does not lie to prevent the investigation.

Damages Recoverable for Wrongful Death of Physician.

The commissioner, whose report is affirmed by the United States District Court, in Pennsylvania, in the case of Ward vs. Dampskibsselskabet Kjoebenhavn, an action to recover damages for the wrongful death of a physician, says that no cases were called to his attention, and his search had not disclosed any, in which the amount of compensation for the death of a physician under similar circumstances was determined. The physician in question, Dr. John M. B. Ward, was at the time of his death 39 years of age. He had been a physician for twelve years. For the last eight years he had been an assistant quarantine physician, selected for his competency. Prior to his appointment as assistant quarantine physician, he had been elected to a position on a hospital staff, devoting his time to bacteriology. At the time of his death he was in receipt of an annual salary of $2,000 and the use of a house and other perquisites estimated of the value of $1,000 more per year. His personal expenses were estimated at $1.000 a year, leaving $2,000 as the yearly sum that his widow and children were deprived of by his death. Under these circumstances the commissioner thinks an award of $25,000 damages proper; and the court concurs therein.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

1 *Mysteries and Sources of Suicide. G. M. Gould, Philadelphia.
2 Shock. L. Waite, Chicago.
3 *Pleurisy with Effusion and Pulmonary Tuberculosis. H. F. Stoll, Hartford, Conn.
4 *Acute Mastoiditis, Its Prevention, Diagnosis and Treatment. J. J. Thomson, New York.
5 *Hay Fever and Persistent Bronchial Asthma Relieved by Treatment Directed to the Antrum of Highmore. J. E. Schadle, St. Paul, Minn.
6 *Possible Danger in the Therapeutic Use of Osmic Acid. A. E. Hertzler, Kansas City, Mo.

1. **Mysteries and Sources of Suicide.**—Gould calls attention to the important part which he believes eyestrain plays in suicide. He thinks that the most convincing and striking proof of the theory of this influence in producing suicide pertains to the time of life at which the numbers of suicides increase, reach their acme and decline. Presbyopia with its doubling and trebling of eyestrain, according to Gould, occasions the increased disease and suicide at the ages of from 40 to 60 years. Gould cites specific instances of victims of eyestrain.

3. **Pleurisy and Pulmonary Tuberculosis.**—Stoll concludes that all effusions within the pleural cavity are to be considered grave, as a large majority of them are of tuberculous origin. Although a positive history is most important, a negative one is valueless in excluding tuberculosis. In the absence of a pneumonia or a septic condition he considers the very presence of a pleural exudate sufficient to raise the question of tuberculosis. Patients with pleuritis should be told that the affection is probably due to the tubercle bacillus. They should be assured that they will get well, but they should be warned to take especial care of their health for a number of years.

4. **Acute Mastoiditis.**—Thomson says that the best preventive treatment of this condition is to keep the patient in bed for several days. A good cathartic is indicated. As soon as there is any bulging, an early and free incision should be made in the membrana tympani.

5. **Hay Fever and Persistent Bronchial Asthma.**—Schadle reports the case of a patient who had been suffering for almost two years with hay fever and asthma. Both antral cavities were irrigated with a warm boric acid solution until the return fluid was clear and free from sediment. The sinuses were then freely insufflated with thymol iodid. This treatment was continued for five days. On the third day the symptoms disappeared. The environment was not changed, nor was any treatment given other than that mentioned.

6. **Danger in Use of Osmic Acid.**—Hartzler states that when a dilute solution of osmic acid is injected into the free peritoneal cavity, particles are carried to the kidney, as in the case of silver chlorid, with the small accompanying hemorrhages. Although the small amount of osmic acid used in the treatment of neuralgia is probably not great enough to jeopardize life, still there is a limit to the amount of the chemical which can be used safely in therapeutics.

7. **Cholelithiasis.**—In his discussion of the clinical history of cholelithiasis, Beck lays particular stress on the diagnosis of this condition by means of the Roentgen ray, which has proven very satisfactory in his experience, and describes his method of operation.

9. Deep Breathing.—Pryor makes an earnest plea for deep breathing as a therapeutic measure of the first magnitude in the treatment of malnutrition characterized by that complex group of symptoms ascribed to neurasthenia, toxemia, indigestion, anemia, gout, and in affections of the lungs and pleura. He says that deformities due to rickets and spinal curvatures are often susceptible of great improvement by combined exercise of the lung and special gymnastics. In delayed consolidation, incomplete resolution, imperfect restoration of function accompanying or following pneumonia; partial consolidation, collapse or carnification of the lung, associated with or resulting from pleurisy with effusion; bronchiectasis and adhesions of the pleura, deep breathing is particularly beneficial. Breathing exercises must be taught and watched to be effective. The lungs should be filled from bottom to top. The object to be attained is increase of the tidal and supplemental, and a decrease of the residual air. If coughing is produced by deep breathing, it is usually beneficial and assists in distending unused lung tissue, stretching or tearing adhesions and dislodging secretion.

11. Tuberculosis of Joints.—Tracy pleads for the employment of correct principles in the treatment of tuberculosis of joints consisting of the fixation of the joint, protection of the joint from weight bearing, and good constitutional treatment. He reports 16 cases.

18 *Appendicostomy and Cecostomy for the Relief of Chronic Diarrhea. S. G. Gant, New York.

18. Appendicostomy and Cecostomy in Chronic Diarrhea.—Gant gives his personal experience in the treatment of 9 cases of persistent ulcerative colitis and chronic diarrhea by means of appendicostomy or cecostomy. In 8 of these cases the appendix was brought up, attached to the skin and opened in order to permit through-and-through irrigation. In the remaining cases the cecum was opened and a catheter introduced, after the method of Gibson, for the same purpose. Gant's experience with these operations has been most gratifying. He says that the operation of appendicostomy is comparatively simple, can be performed quickly and is no more dangerous than is the interval operation for appendicitis. Gant opens the abdomen by a short intermuscular or gridiron incision such as is made for appendectomy. He says further:

> The appendix is located, freed if adherent, brought outside the abdomen, opened and a probe inserted to make sure of its patency. If found to be too short, strictured or otherwise unsuitable, it should be removed and a cecostomy substituted. If, however, the appendix is sufficiently long and patent, it is ligated and cauterized. The cecum at its base is sutured to the abdominal wall and the parietal peritoneum, muscles and skin closed with plain catgut sutures. The appendix is anchored to the skin by one or two sutures and the wound covered with protective tissue and gauze held in place by adhesive plaster. In some cases the meso-appendix is left intact, while in others the artery is ligated and the peritoneum stripped off, but apparently neither method has any advantage over the other. Usually the part of the appendix external to the ligature sloughs about the fourth or fifth day, leaving the open stump projecting about one-fourth of an inch above the skin.
>
> The irrigations are begun immediately, using saline solution, ice water, or solutions of boracic acid, potassium permanganate, carbolic acid, ichthyol, bichlorid of mercury, or nitrate of silver. In practically all cases the abdominal discomfort and frequent evacuations cease immediately after the operation, or after the first irrigation, and within a few days the stools become almost normal, containing but little blood or mucus. It appears to make but very little difference what irrigating fluid is employed, provided that it is used daily and in sufficient quantity to cleanse the bowel thoroughly.

The only unpleasant sequela in Gant's series of cases was a small ventral hernia.

41. Vesical Evacuator.—For several years past Kelly has made use of an evacuator in order to empty the bladder of the last drop of urine when the patient is in the knee-chest position, which is in all respects satisfactory. The evacuator is made up of a tube 18 cm. long in its straight portion and 8 cm. long beyond the bend. It consists simply of a bent tube 3.5 mm. in diameter, through which the urine is drawn by a suction bulb into a suitable glass receptacle. The inside diameter of the tube is a little over 2 mm. in diameter. A cap which screws on the end of the tube is used to push down into the vertex of the bladder as the suction is applied, when there is a free and rapid flow from the vesical vertex into the glass bottle held below the level of the bladder. A little flange near the outer end serves to give the fingers a firm hold.

The value of this simple little instrument is said to be twofold; in the first place, it serves to remove any urine which has not been passed or removed by catheter before putting the patient in the knee-chest position. A few drams of water lying in the vesical vertex may easily prove a source of much annoyance to the examiner—above all, if the patient is not in a good posture. Furthermore, if the operator desires to collect urine from one kidney by means of the ureteral catheter, while at the same time he is collecting the urine from the opposite kidney transvesically by means of a vesical catheter, under these circumstances it is most important to empty the bladder thoroughly just before catheterizing the ureter, in order that the urine which runs into the bladder and then out through the vesical catheter may really represent the kidney not catheterized. Such a method of examining the uncatheterized kidney is always valuable as a means of determining the urea coefficient. It may be valuable, too, for a microscopic and a bacteriologic examination, provided the bladder itself is sound.

42. Caring for Umbilical Cord and Navel.—Burns' method differs from those in general use: 1, In the use of a ligature close to the skin covering of the cord; 2, in the arrangement of the gauze; 3, in the absence of any antiseptic powder; and 4, in the use of cotton between the abdominal band and the genitals. Five minutes after the child is born the cord at the juncture of the skin and amniotic coverings is tied with a silk ligature (No. 10 or 12 twisted silk, or a doubled piece of

knitting silk). The ligature is drawn very tightly, so as to compress the deeply situated blood vessels. Two inches from the navel the cord is clamped with a pair of hemostatic forceps (Pean's five-inch long bite). The cord is held away from the child's genitals by the hemostatic forceps and cut one and a half inches from the navel with an angular pair of scissors. The placental end of the cord is carried by means of the hemostatic forceps to the Kelly pad. Wharton's jelly is squeezed out of the cord by grasping the cord near the navel with the fingers of one hand and stripping with the fingers of the other hand. The cord is tightly ligated one inch from the navel, then the ends of the ligature are carried around the cord to the side opposite the knot and tightly tied.

After the child is washed, the cord and navel region are bathed with a saturated solution of boric acid and wiped perfectly dry. A strip of sterilized gauze of four layers is cut to the size of 7 by 3½ inches. In one-half of this, at about the center of the junction of the lower with the middle third, a hole is cut and the cord passed through it and laid upward on the gauze. The other half of the gauze is folded over the cord. A piece of absorbent cotton is placed above the gauze and the band applied. Between the band and the genitals a piece of cotton is placed to prevent the urine from soiling the dressing. The method has been used with the very best results in the last 100 cases attended by the author, and no harmful effects have been noticed.

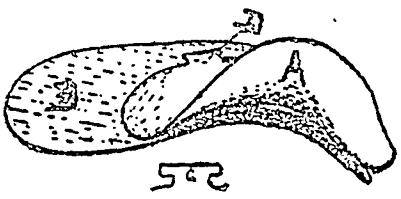
43 Subacute and Chronic Vesiculitis. J. W. Wiltse, Albany.
44 *A Brace to Aid in the Treatment of Flat or Weakened Feet. J. M. Berry, Troy, N. Y.
45 Professional Circumspection. E. Oliver, Ancram, N. Y.
46 Modern Scientific Medicine and Its Relation to Union University. J. D. Craig, Albany.

44. **Brace for Flat or Weakened Feet.**—The brace employed by Berry consists of two parts, a supporting portion (A) and a base piece (B). (C) represents the tongue portion of the support, which fits into the slot in the base piece marked (D).



The supporting portion is made of No. 16, 18 or 20 (depending on the weight of the patient) tempered galvanized steel fitted over a plaster-of-Paris model of the arch of the foot. It supports the arch of the foot and projects high up on the inner side of the foot so that when worn with a properly constructed lace shoe it exerts firm lateral pressure on the foot, thus preventing lateral deformity. It does not cover any of the weight-bearing portion of the heel or ball of the foot and is attached to the base piece in such a manner that it is movable in every direction, thus allowing all motions of the foot to take place. In other words, it supports and holds in position the arch of the foot with the smallest amount of splinting. The base piece serves simply to hold the supporting portion in place. It is made of flexible spring brass so that it readily conforms to the shape of the bottom of the shoe, and when it slips into place in the heel of the shoe the arch supporter is in its correct position.

The method of taking the plaster cast for the brace in question is as follows: The patient sits with the knee flexed and resting on a support in such a way that the outer surface of the foot rests against an upright support. The foot presses closely but not too firmly against the upright support, thus leaving a space between the foot and the support corresponding to the arch of the foot. The support is tilted somewhat to allow the position to be assumed by the patient more comfortably. The arch of the foot is first coated with vaselin to prevent the plaster adhering and with a dermatographic pencil the outline of the brace is drawn on the foot, special care being used in marking out the anterior and posterior limits and the height to which the brace rises laterally. The foot is now put in position on the support and the space represented by the arch of the foot filled with plaster cream. The plaster hardens in a few moments, and on removal the outline made with the dermatographic pencil will be found to have been transferred to the plaster. Any imperfection in this negative cast can be filled with plaster cream, and after this has hardened, the surface is coated with vaselin, the outline of the brace freshened and a positive cast made, especially necessary in all cases where the arch is very low or where edema or swelling has partially obliterated the arch. The cast is now sent to the instrument makers and the steel plate fitted to the outline.

54 *A New Splint for Fractures of the Humerus. G. G. Marshall, Wallingford, Vt.

48. **Prolapsus Ovari in Femoral Ring.**—Parsche reports case of femoral hernia of the ovary occurring in a woman who had a tumor in the femoral region for 14 years, causing her no distress until she over-exercised and the hernia of the ovary became strangulated.

54. **New Splint for Fractures of Humerus.**—Marshall's splint consists of two thin pieces of board fastened to each other at right angles by their long edges. One, longer than the other, is 15 inches long by 3¼ inches wide; the other is 11 inches long by 3 inches wide. In the angle at the lower end is fitted a square piece of material with a slot cut through it near its outer end. Surmounting the upper end of the shorter side of the splint, is fastened a crutch piece to fit the axilla. This piece is also curved forward so that the end will not crowd on to the chest, as the arm rests across the body. When the splint is in position the crutch piece fits closely in the axilla, and the longer side supports the posterior aspect of the arm, while the shorter one supports the inside of the arm. The square at the lower end of the splint extends from 2 to 4 inches below the elbow, according to the length of the arm. Strips of adhesive plaster are applied, one to the inside and one to the outside of the arm, extending up to the point of fracture. At the elbow the strips are folded on themselves so as to cover their adhesive surfaces, and the inner one passed through a slit in the lower end of the piece; the outer strip is passed through a similar slit in the square piece, the two ends drawn tightly and tied. This gives strong extension in the line of the shaft of the humerus. This splint is of special advantage in compound fractures of the humerus as the dressings may be removed without weakening the extension.

58. **Drains and Drainage.**—To dilute the waste matter coming from the rapid changes that ordinarily follow a surgical operation, Cantrell fills a water-bag with normal salt solution and hangs it eight to ten inches above the patient, adjusts the long vaginal nozzle, that has numerous openings, into it so that as the water passes in at some, gas that may want to escape may pass out at others. This is inserted into the rectum and held in place with strips of adhesive plaster passed around the nozzle and then made fast to the patient, the

water is turned on slowly. Cantrell says that it is surprising the quantity that may be taken up in this manner with little or no discomfort, thus facilitating drainage through the natural channels, as well as supplying the necessary fluids otherwise needed.

62. **Epidermal Fibrils.**—Thompson found that in certain animals, in addition to the protoplasmic fibrils of the stratum filamentosum that are present normally in human epidermis, there are well-developed fibrils in the cells of the stratum germinativum. These fibrils are present in the human epidermis only under conditions of increased cell activity. These fibrils, that are prominent in the stratum germinativum of human epidermis under conditions of increased cell activity, seem to increase in direct ratio to rapidity of cell production. The differentiation of these fibrils of the stratum germinativum into the finer fibrils which connect the cells of the stratum filamentosum can be observed under proper conditions of growth and therefore there should be no separation of the fibrils into different groups with various names. This process of fiber production by the cells of the human epidermis is analogous to increased fiber production by various other cells under similar conditions, and may be of importance in identifying or classifying new growths of epithelial origin.

63. **Effect of Incubation on Tumor Cells.**—The experience of Clowes and Baeslack with mouse tumors has demonstrated that a great difference exists not only in the relative immunity possessed by different individuals, but also in the relative virulence of different tumors all owing their origin to the same source. The variations in question can be accentuated by incubation of the transplantation materials previous to inoculation at temperatures varying from 37 to 41 C. In the case of extremely virulent tumors giving a yield of over 60 per cent. under normal conditions, a distinct and gradual fall in virulence accompanies increasing temperatures of incubation until a point is reached at which no further tumors are obtained. On the other hand, relatively inactive materials giving comparatively small yields of tumors under normal conditions may be so stimulated by subjecting them to incubation at suitable temperatures as to afford a large yield and relatively more rapidly growing tumors than were obtained in the normal series. Those tumors which give a small yield under normal conditions, but which give an increased yield on incubation, are either rapidly growing young tumors, or small and hard tumors, or tumors that have been extremely slow in their development, and have in certain cases exhibited indications of a tendency to undergo spontaneous recovery. Those tumors which on inoculation give a large yield at normal temperatures and a gradually decreasing percentage of tumors in the batches inoculated with materials which have been incubated at increasing temperatures are generally fully grown tumors which have developed rapidly and come of a relatively active strain.

64. **Calcareous Degeneration.**—The methods employed by Klotz resemble those of previous investigators. A pure solution of adrenalin chlorid, 1 to 1,000, was injected into the ear veins of rabbits. Microscopic lesions, such as dilatation of the blood vessels, hemorrhages in the brain and aneurismal distensions of the larger vessels, were noted. The most frequent lesions were situated in the descending arch of the aorta, where white calcified plaques formed the chief naked-eye alterations. The aneurisms were found to be situated in the centers of these white plaques which have been described by some as atheromatous areas. Histologic examination shows that these plaques, at an early stage, are situated entirely in the media and that the calcification which occurs here is the secondary result of a degenerative, chiefly fatty, change which takes place in the media. Calcification is never found in the intima, and only rarely are there any intimal changes. The intimal changes which occur are of two kinds; either there is a local heaping up of endothelial cells at a point where no degenerative changes of any kind have taken place, or there is a thickening of the intima underneath the endothelial cells, chiefly due to proliferation of the connective tissues, in which slight fatty changes may occur. Such being the case, Klotz believes that the term atheroma must be discarded in describing the experimental arterial lesions in rabbits.

65. **Colitis in Man and Animals.**—Flexner and Sweet state that the toxin of the Shiga dynasty bacillus is liberated from the bacillus through the process of autolysis. In rabbits the toxin is not absorbed directly in an active form by the gastrointestinal tract; in man, however, absorption of an active poison does take place from the intestine. The toxin is excreted in rabbits, and probably in man as well by the intestine, chiefly probably by the large intestine, which being injured by the act of elimination, reacts by the development of inflammation, etc. In rabbits the characteristic action of the toxin depends on the integrity of the biliary secretion into the intestine. When the bile is prevented from entering the intestine, either by ligature and section of the duct or by establishment of a biliary fistula, no lesions whatever of the large intestine appear, or they are inconsiderable in extent. The loss of toxin through a biliary fistula does not prevent in rabbits the lethal effects which are caused, apparently, by a nervous poison. The tying off of the bile duct seems to prevent the passage of the toxin in amounts sufficient to cause the large intestinal lesions into the blood. The liver, therefore, in this condition tends to hold back the toxin from the general circulation. The peculiar effects of the toxin on the large intestine in rabbits is not produced at once, but would appear to depend on successive acts of excretion of the poison by the bowel. The establishment of biliary fistula reduces the intensity of action of corrosive sublimate on the large intestine in rabbits; and the lesions of ricin poisoning in these animals are also modified by this operation. Dysentery toxin is destroyed by peptic digestion, and also, though probably more slowly, by tryptic digestion. The absence of power of the toxin to cause poisoning in rabbits when it is brought directly into the lumen of the intestine, is not explained by the destructive action of trypsin. The character of the histologic changes in the cecum of rabbits caused by the dysentery toxin, points to an action on the substance and not primarily on the surface of the intestine.

67. **Method for Plating Anaërobes.**—The method described by Zinsser, besides being a facile one for separation, permits the assumption of absolute anaërobiosis. The apparatus used consists of two circular glass dishes fitting one into the other as do the halves of a Petri dish, and similar to these in every respect, except that they are higher, and that a slightly greater space is left between their sides when they are placed together. The dishes should be about three-fourths to one inch in height, they need be of no particular diameter, although those about the same size as the usual Petri dishes are most convenient. The sole requirement necessary for successful plating is that the trough left between the two plates when put together shall not be too broad, a quarter of an inch being most favorable. Into the smaller of these plates the inoculated agar is poured exactly as is done into a Petri dish in the ordinary anaërobic work. Prolonged boiling of the agar before plating is not essential. When the agar film has become sufficiently hard on the bottom of the smaller dish, the entire apparatus is inverted. The smaller dish is now lifted out of the larger and placed, still inverted, over a moist surface—a towel or the wet surface of the table—to prevent contamination. Into the bottom of the larger dish, which now stands open, there is placed a quantity (1 to 2 drams) of dry pyrogallic acid. Into this, over the pyrogallic acid, the smaller dish, still inverted, is then placed. A strong solution of sodium hydrate is poured into the space left between the sides

of the two dishes, in quantity sufficient to fill the receiving one half full. While this is gradually dissolving the pyrogallic acid (and this is the only step which requires speed) albolin, or any other oil, is dropped from a pipette, previously filled and placed in readiness, into the same space, thus completely sealing the chamber formed by the two dishes. If these steps have been performed successfully the pyrogallic solution will at this time appear of a light brown color and the small plate with its agar film will float unsteadily above the other. Very rapidly, as the pyrogallic acid absorbs the free oxygen in the chamber, this plate is drawn down close to the other, and the acid assumes a darker hue, which remains without further deepening even after three or four days' incubation.

4. **Sterile Caseous Matter in Treatment of Tuberculosis.**—Paterson directs attention to a few observations which he has made on the effect produced on tuberculous lesions by the injection of some of the products of the tubercle bacillus as elaborated in the body. He says that it is well known that tubercle bacilli are found in the walls of tuberculous abscesses, but in the contents they may be so few that inoculation experiments may be necessary to demonstrate their presence. The conditions in the interior of such abscesses are apparently

favorable to growth; the serum and soluble toxins pass into the circulation, producing more or less constitutional disturbance, whilst there is a stream of fresh serum, rich in nutritive substances, into the interior; the temperature is most suitable, and still not only do the bacilli not increase, but actually diminish in numbers. There must, then, be some substance in the contents which is inimical to the bacilli and, as the fluids are being constantly renewed, presumably this deleterious material is in the encapsulated solids.

The conditions which exist in an abscess, as regards the relative proportion of caseous matter, can not be produced in the body as a whole, still the possibility remains that the introduction of small quantities might exert a beneficial influence on the disease. But before such injections can be made it is necessary to destroy the living bacilli present, for though these may be so few as to escape notice with the microscope, inoculations show that even in these cases they are present. As it was requisite that the chemical constitution of the solids should be as little charged as possible it was evident that neither heat nor chemicals could be used for the purpose of sterilization, and extreme cold, even though applied continuously for a long time, does not affect the virulence of organisms. Cold applied intermittently was found to produce the desired result. If tuberculous pus be kept in a refrigerator but five or six months, but allowing it to thaw frequently during that time, the pus will not induce tuberculosis when injected into guinea-pigs, even in large doses. Having destroyed the bacilli by this means the serum is poured off and the sediment is then washed for three days in a continuous stream of cold sterilized water to remove all soluble toxins. Sterile normal salt solution is now added to the fine white sediment till each centimeter of the emulsion contains 5 milligrams of solid substance and the material is then ready for use.

Large numbers of animals have been injected with this suspension by Paterson, and in no instance has tuberculosis been produced. If a large quantity be injected into a tuberculous patient there is a well-marked reaction, but a few minims can be given without any evident disturbance. If the opsonic index is to be regarded as the degree of resistance of the body against any particular organism then we have in this substance a means of raising the tuberculous index to a high level and that without any negative phase. In one of Paterson's patients this index rose from 0.5 to normal limits within twelve hours. Such a rapid rise is unusual, but there is no difficulty in raising the index to what is regarded as normal and in maintaining it at that level. The technic necessary to obtain this index is so elaborate that it can only be conducted in a fully equipped laboratory and by a properly trained observer, and so long as it remains in this position it can only be employed in a limited number of cases. In using caseous matter, Paterson has found the temperature a convenient guide to the dose. If sufficient be introduced to raise the temperature from 0.5 degree to 1 degree, the best results are obtained and at the same time the index keeps within normal limits. If there be no rise of temperature the index may still be high and yet little, if any, improvement be observed in the disease. He has found that from 0.1 to 0.5 cubic centimeter of emulsion given every second day is sufficient to raise both index and temperature. Paterson begins with the smaller quantity and increases the amount at each injection till a slight reaction appears.

5. **Anticholera Serum.**—MacFayden conducted experiments which show: 1. That acutely toxic cell juices possessing active immunizing properties can be obtained from the cholera organism by the method employed. 2. That an antibody can be produced for that primary poison which exists as an integral constituent of the cholera bacillus—a matter on which there has been considerable dispute and difference of opinion. 3. That the antiendotoxic power of the serum can be raised to a marked degree—a matter of equal importance. 4. That the serum in addition to its antiendotoxic possessed agglutinative and bacteriolytic properties. 5. That in the case of the cholera organism there exists an intimate relationship between its virulence and toxicity. 6. That the cholera endotoxin obtained under the conditions described is thermolabile, being readily destroyed at 55 and 60 C.

44. **Soluble Endotoxins.**—Besredka states that an endotoxin can be obtained from bacilli by triturating a dry mixture of the bacilli and sea salt and then adding water. These endotoxins are more strongly toxic than any other toxin yet described, but they can be neutralized by corresponding serums

robes. The obtained by intravenous injection of living miceivs invariable temperature at which they are destroyed by heat ipy. for chemi- and characteristic, like the boiling or melting point) cal substances.

46. Great Efficacy of Antidysentery Serum.—Vaimpleinst the Dopter state that the serum of horses immunized age stepitoxic bacillus of dysentery possesses antimicrobian and anill properties which render it useful in therapeutics. This serum is entirely harmless for man, but is proving to be almost specific in the treatment of bacillary dysentery. It has no effect on any other variety. They claim that *it arrests both the infection and the intoxication and insures rapid recovery, putting an end at once to all the intestinal disturbances.* Its effects are more striking the earlier it is used, although it has proved effectual even as late as the sixteenth day. Prolonged and chronic dysentery is also amenable to this serum treatment. These results were practically constant in 96 cases of severe dysentery treated with the serum alone, the number of stools ranging from 15 to 288 a day. The amount injected *ranged from 20 to 100 c.c.,* and the injection was sometimes repeated after twenty-four hours, and again a third time in the most threatening cases. The Shiga-Kruse bacillus had been used to immunize the horses, but the serum proved equally effectual against this and against the Flexner bacillus. The curative action of the serum is so prompt and certain that its prophylactic use seems hardly necessary.

47. Frequency of Tuberculous Infection by Way of Digestive Tract.—Calmette and Guérin supplement their previous publications on experimental tuberculosis with the present article, which relates research with cows. The results show that adult cows, as well as calves, contract tuberculosis by the intestinal route, without any traces to be *found in the walls* of the intestinal tract revealing the passage of the tubercle bacilli through them. *In younger animals* the bacilli are retained more or less completely in the mesenteric glands. They *may* die off in the glands or may entail the formation of tubercles. In adult animals the defensive reaction on the part of the glands is much less pronounced, and the bacilli are generally swept along, *with the leucocytes which have incorporated them, into the lymph circulation and through the pulmonary artery to the lung. Pulmonary* tuberculosis in the adult, supposedly primary, is more often of intestinal origin. In experimental work, infection by way of the digestive tract is the most effectual and the one that conforms best to the normal conditions of natural infection.

49. Transmission of Leprosy to Monkeys.—Monkeys of a low type have been found by Nicolle to be susceptible to leprosy in about the same degree as they are susceptible to syphilis. The findings with anthropoid apes may prove more instructive.

54. Treatment of Trypanosomiasis by the Benzidin Dyes.—Nicolle and Mesnil have been experimenting with other dyes of the benzidin group to which trypan red belongs, and give the details of their research, both in regard to the chemical and the biologic action of the dyes in trypanosomiasis. They found that the dye known as "dichlorobenzidine-acid H" (Bayer) is the most powerful in its curative action and is effectual in the three forms of trypanosomiasis in animals, in nagana, mal de caderas and surra. It has, besides, a very striking preventive action in respect to surra. Their tests were made mostly on mice.

60. Prepared Serum Toxic for the Peripheral Nerves.—Schmidt made an emulsion of sciatic nerves from hogs and *injected it into the peritoneum in guinea-pigs.* The serum of the guinea-pigs acquired in time a destructive property for the peripheral nerves of frogs. The nerves suffered both in their physiologic functions and in their structure.

71. Silver Nitrate and Zinc in Chronic Gonorrhea.—Balz and Tansard report 13 cases treated with nitrate of silver and zinc, the action of the zinc decomposing the silver nitrate. There is thus a production of silver albuminate and of silver chlorid which are deposited on the mucosa lining the urethra. There is, further, a formation of metallic silver, also of traces of zinc chlorid, and, finally, of zinc nitrate, which is the most effectual factor of all in the treatment. To obtain this combined local action they instil 10 to 20 drops of a 1 per cent. solution of nitrate of silver. Immediately afterward they insert a catheter made of metallic zinc, about 32 or 40 in the Béniqué series. The zinc catheter is held in the urethra for a minute or two, until the chemical reaction becomes evident by the pain experienced and by the black discoloration of the vaselin with which the catheter is lubricated. In two minutes this black stain shows that the silver-zinc reaction has occurred, and the catheter is then withdrawn. The catheter should be boiled beforehand in distilled water and cleaned at once after removal. They rub it with potassium iodid until it has resumed its usual color. It loses its polish soon and has to be sent to be repolished occasionally. The efficacy of this combined treatment is established by the cases reported. They affirm seven applications cured the first patient, 9 the second and third, 5 the fourth, and so on, all cases of rebellious chronic gonorrhea in males. The method is probably equally applicable for girls and women, in vaginitis and metritis.

78. Traumatic Ruptures of the Bladder.—Morel reports 3 cases which show the diagnostic importance of finding always the same quantity of urine in the ruptured bladder, *as all the urine* above the point of rupture flows out into the peritoneal cavity. The almost immediate refilling of the bladder is also important. The urine accumulated outside flows back into the bladder as soon as it is emptied. One patient had general paralysis, and this allowed his bladder to become distended *to* the bursting point. The degeneration of the bladder musculature also favored abnormal distension.

81. **Schauta's Experience with Cesarean Section.**—Neumann discusses from various points of view the 175 Cesarean sections performed in Schauta's clinic, with five others done immediately after death. He remarks that this is the largest series of operations yet published from one clinic. He tabulates the various details, showing that 161 of the women recovered including 52 febrile cases, in 140 cases there was no reaction on the part of the wound, while there were stitch hole abscesses in 10 and in the abdominal wall in 8. In 25 cases postoperative bronchitis was observed, with lobular pneumonic foci in 4 and croupous pneumonia in 1. About half of these pulmonary cases occurred during the winter. In one case a latent tuberculous affection of the lungs made itself manifest in the bronchitis after the operation. These respiratory affections occurred about equally with the various anesthetics employed. The importance of these affections is shown by the fact that these cases were all accompanied by fever except in 5 out of the 45. Coughing also has an unfavorable influence on the healing of the wound, being probably responsible for 9 out of the 18 cases in which the wound did not heal by primary intention. In the 14 fatal cases the wound had healed by primary intention in several and death was due to eclampsia in 3 and to other causes in the 6 for which the operation was in no way responsible. In 8 cases the operation may possibly be incriminated, one death being due to asphyxia under chloroform one on the fifth day to pneumonia. The anesthetic in this last case had been Schleich's mixture. Death in another case was the result of axial torsion of the intestine from adhesions consecutive to the Cesarean section. In another case it was the result of hemorrhage from the stump after a Porro operation. Hemorrhage from the stump in a second case was due to pre-existing infection. In the three other cases death was due to infection of the wound, and they emphasize anew the extreme caution necessary in selecting cases for Cesarean section also the necessity for avoiding internal examination of women for whom Cesarean section is contemplated, and, last but not least absolutely certain asepsis on the part of the operating surgeon. Of the 175 children, 164 were living twenty four hours after the intervention, 7 were born dead and 3 died in asphyxia. In 18 cases Cesarean section had been done before in 13 instances at the same clinic. Adhesions were found in all these cases, so large and strong in 2 cases that it was hard to open up the peritoneal cavity. The adhesions were at about the same points as in Haven and Young's material. They show that the ultimate outcome even with modern technic is still far from perfect. The best results were obtained with a sagittal incision, made as high as possible.

83 **Lymph Glands in Carcinoma of the Cervix.**—Fromme is assistant physician in charge of the gynecologic clinic at Halle, and here discusses certain questions connected with cancer of the cervix, among them the cause of the sudden febrile attacks with chills sometimes observed in the course of cancer. He reviews the literature on the subject of the behavior of the lymph glands, and then describes in detail 31 cases from his own experience presenting atypical features. Among other points learned is that the occasional appearance of fever with carcinoma of the cervix must be the result of infection of some of the lymph glands with very virulent micro organisms, which overcome the resistance offered by the glands and pass on into the blood. When the glands are already affected, even slightly virulent micro organisms are able to overcome their resistance. The micro organisms come from the cancer, or enter through some mechanical or chemical injury of its surface. In consequence of the bacterial invasion of the glands a growth of granulation tissue and of connective tissue is stimulated. This may be the work of the cancer toxins alone or associated with living bacteria, or it may follow invasion of the gland by the cancer. This new formation of connective tissue aids in the defense as if the gland is not already cancerous, it opposes greater resistance to invasion by the cancer later, and if the gland is already cancerous, the malignant growth may become encapsulated by connective tissue and be choked out. The gland then seems to be full of a white, greasy mass.

84. **Results of Operative Treatment of Myoma.**—Sarwey analyzes the results of 430 operations for myoma at Döderlein's clinic at Tübingen. Comparing them with others' statistics he finds the total mortality of myoma operations to be 4 or 5 per cent; those done by the vaginal route show 1 or 2 per cent higher mortality and the conservative operations 1 per cent higher mortality than the radical operations. He comments on the great frequency of complications of myoma and declares that they are a strong argument for operative treatment. The ultimate outcome, he says, in cases treated by removal of both ovaries in connection with the radical operation are the best conceivable. Disturbances connected with the artificial menopause were noticed in only a third of the patients, and were always so slight and transient as not to interfere with the working capacity. Danger of trouble in the ovaries later is thus summarily done away with. Conservative operations have several drawbacks, among them the possibility of recurrence and of rupture of the uterus at the point of enucleation. Youthfulness and the express wish of the patient to retain menstruation and the possibility of conception are the only indications, he thinks, for conservative procedures. He advocates not to waste time on symptomatic treatment if it does not soon prove effectual, but to operate promptly after fully instructing the patient in the matter.

85 **Tuberculosis of the Vulva.**—The lesion was removed in the case described on the assumption that it was a cancer, but it proved to be a patch of ulcerated miliary tuberculosis, apparently primary. The patient was a woman of 75, and she succumbed five days afterward to general weakness. An old tuberculous focus was found in the right apex and the glands of the hilus were calcified. The findings in this case throw doubt on some of the published cases of supposed primary genital tuberculosis.

86 **Influence of Disinfection of Vagina on Puerperal Morbidity.**—Baisch remarks that the use of rubber gloves and bacteriologic examination have placed the study of this question on a surer foundation. His article is based on 1,000 spontaneous births in which the parturient was usually repeatedly examined, as many as thirty times in one case. In half of the patients the vagina was washed out with a solution of sublimate. The febrile cases among the irrigated numbered 64, that is, 12.8 per cent., while the unirrigated had only 40 febrile cases, that is, only 8 per cent. Comparing only those in which an internal examination was made, 12.8 per cent. of 500 irrigated and 7.7 per cent. of 373 unirrigated, proved to be febrile cases. Excluding the extragenital sources for the fever, the percentages were respectively 10 for the irrigated and 5.2 per cent. for the unirrigated. Bacteriologic examination before and after showed that the rinsing with a solution of corrosive sublimate was not able to destroy the various germs, especially streptococci and gonococci. It modified the bacteriologic content to the extent that the harmless bacilli were destroyed or overwhelmed by the streptococci which then proliferated unchecked. Streptococcus endometritis was observed in 5 cases among the unirrigated and in 14 cases among the irrigated. The sublimate disinfection has now been abandoned. At present every second parturient is treated by the Zweifel method of wiping out all the blood from the vagina a few hours after birth. The findings to date indicate that autoinfection is not responsible for puerperal fever. The latter seems to be always due to the penetration of pathogenic germs into the uterus. The experience at the clinic has been that 7.6 per cent. of all spontaneous deliveries are followed by fever. The aim should be to prevent access of pathogenic germs to the uterus. The access of germs is favored by anything—such as sublimate irrigation—which reduces the physiologic protecting powers of the vagina. Döderlein's success with lactic acid indicates, however, that the prospect of destroying the pathogenic germs in the vagina is not absolutely hopeless.

88 **Fetation in a Closed Accessory Horn of the Uterus.**—Two cases are described and illustrated and the literature reviewed. Among the points brought out is the fact that de-

fectively developed genital organs are peculiarly liable to infection, especially from the intestines; also that if there is any mucosa at all, menstruation is liable to occur, and in a closed organ the menstrual blood may be absorbed.

90. **Kidney Functioning in Congested Kidney of Pregnancy and in Eclampsia.**—Büttner states that the urine in the congested kidney of pregnancy, during normal delivery and during the convulsions of eclampsia, exhibits the characteristics of insufficiency on the part of the kidneys, evidently due to defective blood supply. This in turn, he is convinced, is the result of spasmodic contraction of the blood vessels in the kidney. The convulsions in eclampsia are probably due to spasmodic contraction of the arteries in the brain, but the assumed toxin causing this vasoconstriction is still mere conjecture.

91. **Nucleo-Proteids in Septic Affections.**—Pollak discusses the various theories in regard to the mechanism of immunization, immunity and serum treatment, and then describes 2 cases in which he injected nuclein and salt on theoretical premises in regard to the action of the nucleo-proteids in septic affections. He injected the mixture subcutaneously so as to take advantage of its leucotactic properties to the fullest extent. The prompt benefit that followed encourages him in advocating general adoption of this means of treatment built up on the broadest principles, aiming to increase by artificial aid the resisting powers of the organism in its struggle with streptococci by supplying to the organism some preparation of nuclein. The beneficial effect may not be due to the nucleic acid alone; the albuminoids of the nucleo-proteids certainly participate in it.

93. **Formation of Leucotoxin Under Roentgen Treatment.**—Milchner and Wolff exposed an extirpated but surviving spleen to the action of the Roentgen rays. Severe pathologic changes became evident after a few hours, while another spleen under the same conditions but not exposed to the rays showed normal structure. The extract of the exposed spleen, injected into animals, rapidly reduced the numbers of leucocytes. Injection of the unexposed spleen was followed by marked leucocytosis. Their research also confirmed in other ways the generation of a leucotoxin under Roentgen action.

94. **Superheated Air Plus Calomel and Iodin in Treatment of Tuberculosis of Mucosæ.**—Holländer reiterates that ascending tuberculous processes of the mucosa of mouth and nose occur much more frequently than is generally recognized, both in connection with lupus and without it. In contrast to the descending form, in which the condition of the diseased lung dominates the clinical picture, the prognosis is not unfavorable. The ascending variety displays a pronounced tendency to heal after removal of the primary focus, and complications in the lungs run a mild course. Treatment with superheated air without direct contact is capable of realizing a complete cure. In his extensive experience during the last ten years not a single case has shown itself refractory to this treatment. His success with quinin plus iodin in erythematous lupus encouraged him to try iodin in these tuberculous processes, with calomel for the local chemotactic agent. Fifteen minutes before applying the calomel he administered a tablespoonful of a 5 per cent. solution of potassium iodid. The calomel was applied as a dry powder to the lesion on cotton and left for twenty-four hours, or it was rubbed into the mucosa of the gum or a 1 or 2 per cent. oily suspension was injected directly into the tissue. The latter method induced necrosis of the tissues, but after the necrotic tissues were absorbed or thrown off the process was found remarkably influenced for good. In laryngeal tuberculosis he advises insufflation of the calomel. The most striking results obtained by this treatment were in the case of a girl with extensive lupus of the lip and upper gum. The entire upper lip had fallen in from the ulcerative process and she was unable to eat solid food. The calomel tampons were applied and the iodin given twice a day, and in the course of five weeks the entire process had healed. He has found it extremely beneficial in tuberculous processes in the bladder. He has treated over 100 patients with tuberculosis of the nasal mucosa, 30 with tuberculous and lupous processes in the mouth and gums, about a dozen patients with tuberculosis of the lips, including 2 with isolated primary tuberculosis, and a patient with extensive tuberculous processes on the tongue. In 3 cases he applied the superheated air to the larynx after laryngotomy. In 2 cases the process was of the descending type and the results of treatment were not satisfactory; in the other it was ascending and the patient was cured. In conclusion he urges more general adoption of this iodin-calomel treatment in tuberculous affections of the bladder mucosa as well as in those of the larynx and mouth.

98. **Dietetic Regulations at Health Resorts.**—Pariser describes the way in which the physicians of Homburg have satisfactorily solved the problem of providing a suitable diet for the various classes of patients taking treatment at the spa, without attracting attention to the patient or inconveniencing the hotel or boarding-house management. The affections most common among the patients are chronic gastric or intestinal catarrh, with diarrhea, chronic constipation, diabetes, heart affections, gout, nephritis and neurasthenia. Four special diets with a few subclasses have been found to answer the purpose, diet 1 for gastric affections, 2 for intestinal catarrh with diarrhea, 3 for constipation and 4 for diabetes. The local medical society supplies the landlords with the booklets containing the list of 220 different articles or dishes. The landlord marks the price opposite the dishes he intends to serve on that special day, or makes up the table d'hôte from the list. He is supplied with a fresh lot of the booklet menus for each day. Opposite the name of each dish are the figures 1, 2, 3 and 4 in parallel columns or the space for one of the figures is left blank. The absence of the figure shows that the dish is forbidden in the diet represented by the figure. The booklet contains also a brief presentation of the principles that guide the selection of the diet, with also general and special remarks. These booklets are supplied at cost price, and have been gratefully accepted by the landlords, while from the medical and scientific standpoint they are regarded by all who have seen their workings as a great advance. The daily booklet menus are supplemented by a large wall table that hangs in each kitchen and bears in large type the four "diets" and subdivisions. The forbidden dishes are printed in red ink, the others in black. The table contains also a few of the "guiding principles" in a brief summary. The system has been in use now for a year or so, with, it is said, constantly increasing satisfaction on the part of all concerned and great benefit to the patients. Each patient is given a separate booklet containing only the diet prescribed for his individual case when he enters on the "cure."

101. **Thyroid Treatment of Obesity.**—Rheinboldt gives the details of 4 cases of obesity in which thyroid treatment was given, supplemented by copious ingestion of albumin, to supply the demands of the over-nutrition consequent on the thyroid treatment. While the thyroid extract is being taken he assumes that about 3,000 calories above the ordinary are required, and if this extra supply is not given from without, the patient's own albumin is drawn on and his general health suffers. In the 4 cases described the treatment proceeded without

the slightest by-effects, which Rheinboldt accepts as confirmation of his theoretical reasoning. He urges that the thyroid treatment should be begun very gradually, and the dose always be restricted to the effectual minimum. The tablets must be thoroughly chewed. At least 20 per cent of the calories needed should be supplied in albumin, preferably meat. In his experience the elimination of water was much promoted by the thyroid treatment.

107 **Relations Between Physical Behavior and Action of Drugs**—Frey shows how the physical properties, the solubility in water or oil, the dissociation into ions and the diffusibility are important for the medicinal effects of drugs Sufficient has already been learned to explain many of the effects observed as he illustrates by specific examples

109 **The Desmoid Reaction**—Sahli warns against the desmoid capsules on the market, having always insisted that the physician must make the little desmoid bag for himself at the time of using for reasons which he states Physicians who have not had successful results with the desmoid test have many of them confessed that they knew of Sahli's work only by brief summaries in other journals and he says that it is not fair to any method to decry it from tests made in ignorance of the author's minute technic

110 **Splitting of Fat in the Stomach by Action of a Ferment**—Heinsheimer's tests were made on animals and on a young woman with an artificial esophagus who submitted to various series of experiments the first instance of the kind in an adult The gastric juice was collected as it flowed naturally, free from admixture of intestinal or pancreatic secretions The fundus secreted a specific ferment which contained a fat-splitting ferment This ferment seems to be exceptionally active in infants

113. **Inheritance of Maternal Characteristics by Larvæ.**—Peter's experiments were with the larvæ of the echinus or sea urchin, and they showed a marked transmission of maternal characteristics without admixture of the paternal. The findings suggest that the laws of heredity are more complicated than hitherto assumed and that different organisms are regulated by different laws.

114. **Research on Absorption of Fat in Intestines**—Bleibtreu describes the technic with which he was able to study the absorption of fat in the isolated, ligated intestine. Cats were the animals used and the substance injected was a soap in the nascent phase An emulsion of cod-liver oil or olive oil was emulsified by shaking it in water with a little dilute soda solution. To this was added a little dried, pulverized cat pancreas tissue and some bile or solution of salts from ox bile. The needed alkaline carbonate was supplied by the mucosa of the intestine. This mixture was injected into the isolated intestine and the abdomen closed. When examined six or eight hours later, the chyle vessels were found as surcharged with fat as after a copious meal of milk. A control loop without the addition of bile to the mixture showed none of this absorption He thinks that the technic described will be found useful for further research on intestinal absorption.

116 **Senile Atrophy of Ocular Muscles.**—Thiele describes a case and suggests that what is generally called amyotrophic atrophy of the ocular muscles is in reality merely senile atrophy.

118 **Modification of Virulence of Micro-organisms by Cultivation in Other Species.**—Loeffler reports among other findings that the germ of foot-and-mouth disease loses its pathogenic properties for cattle after passage through young pigs. He describes the technic by which germs thus modified by being cultivated in animals of other species can be utilized for protecting immunization.

119. **Gram Staining Technic**—Loeffler has been experimenting with various dyes to improve the Gram technic, if possible. He obtained much better results with methyl violet 6 B and methyl violet BN dissolved in a 1 or 2 5 per cent. aqueous solution of carbolic acid in the proportion of 1 to 10. The first mentioned is most excellent for all the micro organisms tested except the pneumococcus; for this the second dye is preferable. The carbolic solution must be freshly prepared

120 **The Biologic Blood Tests.**—Uhlenhuth has found that dirt straw, urine, tuberculin and various other substances liable to be encountered with a specimen of blood sent in for examination "divert the complement"—which is the basis of the hemolytic blood test recently put forth by Neisser and Sachs, mentioned on page 310 of the last volume of THE JOURNAL This possibility of error deprives the test of accuracy under ordinary conditions, although not detracting from its value in the laboratory where extraneous contamination can be excluded Comparative research with the two methods, the hemolytic and the precipitating biologic test, gave instructive findings among others in regard to inoculation of monkeys with normal human albumin for serodiagnosis of syphilis for instance.

121 **Record of Movements of Heart at Left Auricle.**—Minkowski has devised a means to record the movements of the left auricle by a registering apparatus connected with a sound introduced into the esophagus under Roentgen control. He uses an ordinary soft Jacques sound with an opening in the side, over which is drawn a long, narrow rubber bag tied above the opening By blowing into the sound the little bag is inflated The sound above is connected with a Jaquet sphygmocardiograph and the heart beat, as felt in the esophagus, is registered on the drum The bag is inflated until it fits tight in the esophagus opposite the heart, without pressure Specimens of curves thus obtained are given.

122 **Action of Diuretics After Removal of Kidneys.**—Both kidneys were excluded by a ligature in rabbits and various diuretics then administered or injected The results demonstrate. Weber thinks that the diuretics of the caffein group not only affect the endothelium of the kidneys, but also the extrarenal capillaries and thus they promote metabolism They act not only on the kidneys, but have also a general capillary action

123. Albumosuria and Albumin Metabolism.—Allard and Weber report the findings in a carefully studied case of albumosuria in a man of 54. The amount of albumose eliminated was out of proportion to the possible sources ingested, especially during febrile states, suggesting that the albumose was derived from destruction of the organic albumin.

124. Bronchial Asthma.—Strubing gives a comprehensive analysis of the various theories that have been suggested in regard to the etiology of bronchial asthma. For diagnosis and treatment it is indispensable that the various disturbances should be sharply differentiated and each one traced to its true origin. When the asthma has developed on the basis of a neurosis, other nervous manifestations are liable to be encountered. He has found it possible to train healthy persons until they could imitate the attack of asthma. By the same means he believes it possible to train the asthmatic until they can control the attacks and finally cure them altogether. Treatment based on this principle will be described in a later communication.

125. Abdominal Actinomycosis.—Friedrich states that in fully 4 per cent. of the 200 patients operated on at Greifswald for inflammation of the cecum during the last three years, the lesion proved to be actinomycosis. Of the 8 patients treated by extensive resection into sound tissue, 7 are still living in good health. It has been the experience hitherto that the affection is liable to recur during the fifth to the sixth year after two or three years of peace, but the patients in the cured cases seem to be perfectly well.

126. Suction Therapy for Differentiation of Malignant Tumors.—Ritter has found suction cups extremely useful for aspirating particles from tumors and fistulas for microscopic examination without danger of hemorrhage or of accelerating the growth of the tumor. In one case described a dubious tumor in the upper abdomen showed fluctuation. A puncture opening was made with a wide cannula and a cupping glass, such as Bier uses for the breast, was applied daily. In a few days the edema had subsided and the tumor could then be palpated. Jelly-like masses were aspirated by the suction, and the patient was much relieved and gained five pounds in weight in seven weeks. The opening was enlarged by a small incision and scraps were obtained for microscopic examination by means of forceps introduced into the tumor through this opening. He has applied this suction therapy in a number of other cases, mostly inoperable cancers. It always brought great relief, while no untoward effects were observed in any instance. In the exceptional cases requiring unusual diagnostic measures the suction cup will be found very useful.

127. Closure of Esophagus from Stomach.—Sauerbruch and Haecker report experiences on dogs which suggest that the stomach closes the entrance into the esophagus by a kind of valve caused by the pressure of the fundus on the esophagus. This is sufficient to prevent reflux of stomach content into the esophagus even after the cardia has been completely excised. But if the vagi are severed, the swallowed food does not pass down into the stomach, showing that peristaltic action is necessary to overcome this valve closure of the entrance into the stomach.

128. Chorea of Pregnancy.—Martin states that in all his extensive experience with chorea in pregnant women he was never compelled to interrupt the pregnancy except in 3 cases. Medicinal treatment always proved sufficient to conquer the trouble in others. In these 3 cases the menacing chorea rapidly subsided after expulsion of the ovum. Two of his patients exhibited chorea with each recurring pregnancy. In one patient the chorea developed in a pregnancy after an attack of acute articular rheumatism after a normal pregnancy, and reappeared in the succeeding pregnancies with increasing intensity. He advocates bromids, although iron and arsenic may suffice for the milder cases. His formula is sodium bromid and ammonium bromid, each 2 gm., and magnesium bromid 4 gm., in doses of from 2 gm. to 8 gm. a day. He never found it necessary to go above these doses. Complicating endocarditis and meningitis, of course, are indications for more energetic measures. He never observed any untoward effects during the long continued bromid treatment, although 13 days after its discontinuance in one case two attacks of heart weakness were observed. They certainly had some connection with the bromids which had been taken for 81 days.

129. Anterior Colpohysterotomy.—Jung says that 3 out of 8 women treated by anterior colpohysterotomy succumbed to previously existing affections which had been the indication for the intervention. He asserts that this operation should be restricted to cases in which there is direct danger for mother or child, or both, and the soft parts are still unprepared for delivery. Such conditions are observed in eclampsia, severe nephritis, uncomplicated heart defects, premature detachment of the normally located placenta, and in acute general affections such as pneumonia. Under other conditions, anterior colpohysterotomy should not be done, enticing as it may appear.

130. Treatment of Perforating, Infected Wound of the Eyeball.—Schirmer has had only 2 cases of sympathetic ophthalmia in 157 cases of perforating, infected lesions of the eyeball. He ascribes this fine record to his energetic treatment with mercurial inunctions, saturating the system with mercury, by inunctions of blue ointment, rubbing in every day from 6 to 9 gm. until he has used up from 150 to 200 gm. in the course of nine to twelve weeks. A few instances of mild stomatitis or mercurial exanthem required the suspension of the inunctions for a few days, but otherwise he met with no signs of intolerance. A most important factor in treatment is the bed rest which he enforces until all inflammation has subsided, sometimes for from four to six weeks. Getting up too early is almost invariably followed by recurrence of inflammation. The inunctions are made morning and evening, rubbing in half the daily dose each time. This general mercurial treatment is completed by subconjunctival injection of 0.3 c.c. of a 1 to 2,000 solution of corrosive sublimate. By this energetic general and local mercurial treatment he has saved many eyes when the patients were on the point of having them enucleated. Sympathetic ophthalmia developed in only two instances and in one the systematic mercurial treatment had not been attempted. In the other an operation had been done on the second eye. The impregnation of the entire system with mercury affects the disease germs not only in the eye, but wherever else they may lurk. He was able to save 103, that is, 66 per cent., of the 157 injured, infected eyes that have come under treatment during the last ten years. Ninety, or 57 per cent., were left with more or less vision. Sympathetic ophthalmia was never observed during or within three months of the course of mercurial treatment. The main points are to give enough mercury and to keep it up long enough. Out of 41 cases in which there was still a foreign body in the eye, the results were excellent in 27. The outcome was even better in the cases with retained foreign body than in those without. The iron splinters were always extracted with the magnet. The results in all cases were far better the earlier the treatment was commenced.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interest of our readers.

A TEXT-BOOK OF GENITO-URINARY DISEASES, Including Functional Sexual Disorders in Man. By L. Casper, Professor in the University of Berlin. Translated and Edited with Additions by C. W Bonney, B.L., M.D., Assistant Demonstrator of Anatomy, Jefferson Medical College, Surgeon to the Southern Dispensary, Philadelphia. With 213 Illustrations and 23 full-page plates, some in colors. Cloth. Pp. 618. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co., 1906.

REPORT OF THE ROYAL COMMISSION ON THE DECLINE OF THE BIRTH-RATE AND ON THE MORTALITY OF INFANTS IN NEW SOUTH WALES. Vol. I. Together with Copies of Commissions, Diagrams, Statistical Evidence and Statistical Exhibits, etc., 1904, second session. Paper. Pp. 97. Sydney: William Applegate Gullick, Government Printer, 1904.

A TEXT-BOOK OF SANITARY AND APPLIED CHEMISTRY, or The Chemistry of Water, Air and Food. By E. H. S. Bailey, Ph.D., Professor of Chemistry, University of Kansas. Cloth. Pp. 343. Price, $1.40. New York: The MacMillan Company, 1906.

TRANSACTIONS OF THE MEDICO-CHIRURGICAL SOCIETY OF GLASGOW, edited by H. McLaren, M.B., C.M., Editorial Secretary to the Society. Vol. V. Sessions 1903-1904, 1904-1905. Cloth. Pp. 301. Glasgow: Alex. MacDougall, 1906.

PROPRIETARY MEDICINES.*

A. JACOBI, M.D., LL.D.
NEW YORK.

Goethe once said that the most interesting book that could be written would be a treatise on human errors. In that book, large like a library, the history of quackery—well meant or deceitful—would fill a large place. The distrust of medicine and its powers is as old as the world, for not many ever knew or cared to appreciate what medical science or art is capable or not of accomplishing, or should be held responsible for. Besides, the more uncultured or uncontrolled the human intellect the greater is the predominance of mysticism. In Greece quackery was rife and Aristophanes made it the subject of ridicule. The elder Cato, who advised the use of cabbage against all sorts of disease and employed witchcraft and incantations for luxations, demanded the expulsion from Rome of the Greek physicians. The iatromechanics, who taught the direct interdependence of stars and man and prescribed pills compounded during the conjunction of Jupiter and Venus, and the medieval priests who cured with prayers and processions and auto da fés, must surely have met with failures and driven the sick somewhere else. Even the specialists among the saints, St. Anna the ophthalmologist, St. Judas the doctor for cough, St. Valentine for epilepsy, St. Rochus the veterinarian, may have made mistakes and proved incompetent.

Nor was the public always edified by the doctors in other respects. Hippocrates complains bitterly of the contests of doctors among each other. More than 2,000 years later Peter Frank thought and advised seriously that the only way to procure an orderly consultation was to call in the police. The maltreatment they were exposed to in the Middle Ages, the contempt in which wounds and ulcers were held, so that the medical faculty of Paris about 1300 committed their candidates by oath not to practice surgery; the barbarous methods of treatment by fire for the dangerous body fluids to which everything was attributed, and afterward the nauseating draughts with which the sick were punished until no better man than Hahnemann tried to redeem them—all that did not contribute to add to the dignity of the profession and to the confidence of the public. All that drove the masses into the arms of the sectarians and the quacks.

Then followed the era of scientific medicine, little more than half a century ago. It was built up on anatomy and physiology and was studied on biologic lines. We should have suspected that the darkness of quackery would disappear before the new light. On the contrary, it has grown in geometric proportions until the accumulated ignorance of quacks and fakers has become a power in every land. The Germans, who like to style themselves the nation of thinkers, have more quacks than any other people. Indeed, Saxony and Bavaria have one quack to two regular physicians; Berlin itself has two to nine. It is in Berlin that 29 per cent. of the men among the quacks—including clergymen, workmen, stewards, bathhouse keepers, shepherds and university students—and 14.4 per cent. of the women had, before embarking in the practice of doing the sick people, collided with the law courts on account of theft, forgery and sexual crimes. It is Berlin that has a judge who, in discharging one of that ilk, said the man deserved the greatest confidence, for he was in possession of very good prescriptions obtained from the servant of a famous dermatologist.

Scientific medicine, as developed by the Vienna school more than fifty years ago, ended in nihilism. Patients, however, would not long be satisfied with being merely percussed and auscultated and autopsied. They had the pardonable wish to be healed and cured. But the only chance they were given was to serve as scientific material. With that they were not pleased and ran off to fill the offices and the coffers of the quacks. Then, after Skoda and Rokitansky, came Virchow, the great man of the century, the enemy of mysticism and obscurantism, the daily discoverer of new facts and new methods in pathologic anatomy, the founder of the cell theory, the great anthropologist and hygienist, the assiduous therapeutist of the individual man and of society, the very realization of what Aristotle meant by his "politician," that is, the philosophical and scientific statesman. The great mistake of his life resulted from his democratic confidence in the people. His idealism moved him to believe that the people would instinctively distinguish between the physician and the quack; it was on his advice that the Prussian parliament opened the doors to the fakers and reduced the medical profession to a trade. That was in 1869. He learned too late that people do not know who is who in medicine. People are not even taught by lectures or pamphlets or books, which are superfluous to the physician and not read by the masses. It is their nature to prefer to be in opposition at all hazards. They would rather pay hundreds of millions annually for pseudo-doctrines as displayed in books and journals and for proprietary medicines.

Do you care to know about how many there are? Up to Oct. 12, 1900, there were United States patents for 321 disinfectants, 30 extracts, 48 hair dyes and tonics, 180 insecticides, 376 internal remedies, 56 plasters, 371 topical remedies, 78 veterinary medicines. There were trademarks for drugs and chemicals, 319; medical compounds, 5,794, which increase at the rate of 250 annually. The State Board of Health of Massachusetts has examined about sixty proprietaries for their percentage of alcohol, according to the board's report

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Howe's Arabian Tonic, "not a rum drink," contains 13.2 per cent.; Parker's Tonic, "purely vegetable," recommended for the cure of inebriates, 41.6 per cent.; Schenck's Seaweed Tonic, "entirely harmless," 19.5 per cent; Copp's White Mountain Bitters, "not an alcoholic beverage," 6 per cent; Greene's Nervura, 17.2 per cent.; Hoofland's German Bitters, "entirely vegetable and free from alcoholic stimulants," 25.6 per cent.; Kaufman's Sulphur Bitters, "contains no alcohol," 20.5 per cent. and no sulphur; Whiskol, "a non-intoxicating stimulant," 28.2 per cent.; Golden's Liquid Beef Tonic, "for treatment of alcohol habit," 26.5 per cent.; Hood's Sarsaparilla, 18.8 per cent.; Peruna, 28.59 per cent.; Lydia Pinkham's Vegetable Compound, 20.61 per cent.; Kilmer's Swamp-Root, 7.32 per cent.

We, the doctors, like Virchow, our great master, are responsible for a great deal of this injury that is done to the people. For a baby it is we that prescribe artificial foods, the composition of which we do not know. What Nature gives us at a low price—milk, cereals, salt and sugar—we know and therefore underestimate. Nature is democratic and offers the best she has for the rich and the poor alike. We covet what is unknown and high-priced. We prescribe nostrums of known or unknown composition; the latter is not far from criminal, the first would be excusable but for two reasons. One of them is that the manufacturer looks for the good he can do to himself, and that factories are not run for your benefit; the second is that an unalterable formula, though its composition may correspond with the label, should not be used by the physician who deals with a variety of cases, ages and circumstances. I do not blame a layman who indulges in self-medication after being treated by his physician with a remedy he sees advertised in the glowing headlines of his daily paper. I have known at least one of the infant foods that was advertised and sold for twenty years, and then publicly discarded by the manufacturer, who claimed to have at last found the proper — probably cheaper — compound. The layman must be excused for refusing to pay a doctor in addition to the advertising expenses of the tradesman.

We physicians do more. We take medical journals that advertise nostrums, that print "reading notices" of proprietary medicines, old and new; that sell pages of their issue to the trade; that print eulogies of factory products in the shape of "original articles;" that alternate their medical and advertising pages. When I spoke of this abomination before the International Medical Congress of Paris in 1900 a Western medical journal of that style asked the appropriate question: "Who, after all, is this Dr. Jacobi? If it had not been for us, the journals, he would have lived and died in obscurity."

Thus it is that even the mind of the medical man is gradually poisoned. What these sheets do not, perhaps, accomplish fully, the glib agent—sometimes an M.D., who gains access to you by the card he sends in to you—will complete. He dumps his wares—his blotters, inkstands, paper-knives, pencils, blank books and almanacs—on your table, either personally or through the post-office. Well, he can afford it. For the poisonous anilin preparation with sodium bicarbonate which he baptizes with a hybrid name and which is prescribed by thousands of us yields him a thousand per cent. of profit. And how? It has been given admission to what should be your sacred medical book, the United States Pharmacopeia. That is why you find thousands of doctors and hundreds of apothecary shops with stacks of advertising sheets and quackish booklets, but without a United States Pharmacopeia or the American Pharmaceutical Association's formulary. That is why a friend found the expensive prescription of a prominent New York practitioner which read: "Remedium Spontaneum, Radway," and which meant no less than merely cheap "Radway's Ready Relief." The same friend took the trouble of examining 50,000 prescriptions compounded in a number of drug stores. Between 1850 and 1873 he met on the prescriptions of physicians no nostrums and no machine-made tablets; in 1874, 1 in 1,500; between 1875 and 1880, 2 per cent. of them; 1880-1890, 5 per cent.; 1895, 12 per cent.; 1898, 15 per cent.; 1902-1903, from 20 to 25 per cent. In a large drug store, one of the gaudy ones, to which the prescriptions of our fashionable doctors are sent, I was assured that 70 per cent. of the prescriptions sent in by reputable physicians contained either nostrums pure and simple or as a part of a compound.

Perhaps it would lead too far to examine all the reasons for that demoralization. But one of them should be generally known and appreciated, which is that there are very few medical schools a graduate will leave, diploma in hand, with the knowledge and practice of writing a prescription. Our medical schools neglect their duties by thus omitting to teach the art of medicine in combination with what is exclusively, and pompously called "science." Let the schools remember what every one of us general practitioners can tell them, that medicine means both science and art. I have here the prescription, dated April 14, 1906, which was given to a patient, who swallowed the stuff, by the professor of pharmacology and therapeutics in one of the great universities between the Atlantic and the Mississippi—very far from the Mississippi—which is a mixture of scientific and queer langage, viz., "Bili-salol"—what is bili-salol in the Pharmacopeia?—"0.25, dentur tales doses No. C, three to five pills after meals three times a day."

If there is so much proprietary medicine prescribed, and so much quackery, clear your own skirts, professors and doctors. The quacks and manufacturers smile at our unctuous words and unclean hands.

PROPRIETARY MEDICINES AND THEIR ABUSES.*

GEORGE DOCK, M.D.

ANN ARBOR, MICH.

Proprietary medicines are substances which some one has an exclusive right to make or sell for medicinal purposes. The exclusive right may depend on secret methods of manufacture, or on a patent on the method of preparation, as in Germany, or on process and substance both, as in America, or on a copyright on the substance. A patent on the name, or a copyright, is one of the most effective methods of acquiring and maintaining exclusive rights in the case of medicines whose virtues are fictitious, though secrecy is in some cases equally effective, for a time.

Proprietary medicines are not either good or bad by reason of their origin. In the language of the day, none are "ethical" or "unethical" *per se*. The possibility of greatest danger occurs among secret preparations and depends partly on the fact that secrecy regarding a remedy may have more serious consequences than secrecy in the manufacture of steel or rope and many other indispensable articles. The chief objection is that no dependence can be placed on the constancy of action of such substances, and that no certain comparisons can be made of observations on their action. They are not fit for scientific deductions.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

There is no essential difference between proprietary medicines advertised exclusively to physicians and those advertised to the general public—the former in medical periodicals or special circulars, the latter in newspapers, handbills or almanacs, or on rocks, fences and barns. These are, perhaps, more frequently of secret composition, but recently this difference has been abandoned with great ostentation by some makers of so-called "patent" medicines. One or the other may be honest in intent and harmless or even useful in effect, just as either one may be fraudulent in conception and dangerous in use. The same lawless nomenclature is followed in both cases, the euphonious or hideous, outlandish or suggestive names being much alike in all. As a further evidence of similarity, a preparation that begins most blatantly in newspapers or on fences may in time find a welcome in reputable medical journals, and, on the other hand, a remedy first advertised to and used by physicians may in time be advertised in newspapers or form the leader in a cut-rate drug store or on the drug counter of a department store.

It is difficult to discuss proprietary remedies in a comprehensive way, but impossible to specify without becoming lost in the endless confusion they present. Certain classes stand out prominently. So there are synthetic compounds, active principles and new salts, real discoveries in chemistry that may have the virtues and drawbacks of chloral hydrate, sulphonal, urotropin, of salol, codein, cocain and others. They are usually put on the market with very little preliminary testing, but with the most sweeping claims. There are mixtures of these with other substances, sometimes representing an advance in pharmacy, often not. Then, there are preparations, whose chief recommendation is that they are of pleasing appearance or taste—"elegant," in the language of practical pharmacy. Though no more efficient than plainer preparations, they seem capable of filling a useful purpose, but are often hampered by secrecy of composition or unfounded claims of far-reaching therapeutic action. Expensive advertising and lavish distribution of "samples," neither of which should be necessary in legitimate trade, enormously raise the price at which these are sold.

It is unfortunate that the laws and customs of ownership do not permit a clearer separation of various classes. There is a deep-seated objection, on the part of most physicians, to the taking out of patents on such inventions as instruments or drugs, but it seems to me that this attitude is wrong in principle and partly responsible for a good deal of the demoralization now obviously existing. I am speaking, of course, of genuine discoveries and not of mixtures or formulæ.

It is a curious and paradoxic fact that no objection is made to physicians taking out copyrights on books, yet there is no essential difference. In the present organization of society, it is not only legal, but natural and proper, that any one making an invention or discovery of value should be able to realize a material return for his pains or ingenuity, and this right can best be preserved by patent. Jenners and Pasteurs will doubtless continue to investigate without hope or expectation of gain, for the love of experimentation, and will achieve not only glory, but also more material rewards, but that is no reason for checking inventive talent of a lower order. The man who invents a new dye may make a fortune. Why not the man who invents a drug that will do for pneumonia what quinin does for malaria?

Regarding instruments, if not protected, imperfect imitations are put on the market. No one is benefited except the makers, who deserve only the ordinary returns for their part of the transaction. If the inventor wishes to lower the price he can easily forego his royalties and give the buyer the benefit. I do not intend to discuss the question as to the profit derived from patents on books, instruments or medicines, though there is a matter for discussion on this point, but merely to emphasize the propriety of allowing inventors or authors to control, for a time at least, the manufacture of their products. The incidental fact that the price of the article may be enhanced by the patent does not affect the question materially. Prices of medicines will always be regulated, like other commodities, by the law of demand and supply. If fashion causes an elevation of price beyond the real value of the article, as occurs with many other things besides drugs, this does not seem a sufficient reason for interference with the well-known laws of trade.

Perhaps the strongest objection against the owning of patents on instruments or medicines by physicians, but one that is rarely expressed, is the danger of abuse in ways not open to the usual objects of trade. An author can hardly stimulate the sale of a book in any but obvious ways, but a medical man, especially if he has a reputation as a scientist, might excite an artificial demand for an instrument or a new remedy. Yet the danger of this is much more likely to exist, and to a greater degree, if the ownership is disguised, as it may be now, and in fact sometimes is. Publicity in such a case, as in others, seems the most promising check to dishonesty either intellectual or financial.

So far I have assumed that a proprietary medicine may be of value. Such a medicine may even be of very great value. Many of the newer nostrums, some of the very ones most objectionably advertised, have not only been imitated by manufacturing pharmacists openly patronized by the profession, but have even been admitted to the Pharmacopeia with a haste not characteristic of sound therapeutics.

I do not think we realize clearly enough the enormous waste of time and energy in the trial of new remedies. Many are doomed to early oblivion, as a perusal of the advertising pages of any series of medical journals makes clear. Just as the names of nostrums advertised in newspapers and trolley cars change year after year, so do those in medical journals. Many others would disappear, but for costly advertising, which is, of course, paid for by the purchaser.

Two sets of evils follow from this ever-changing but never-ceasing flood. On the one hand, the layman has perpetuated or strengthened in him the belief in the magical properties, as distinguished from the physiologic effects, of medicines—the faith in drugs as substitutes for right living. Or, as in the development of bacterial therapy and prophylaxis, he has set up a hope, if not a trust, in the use of antibodies in place of efficient public hygiene, e. g., typhoid inoculations instead of pure water and proper sewage; antirabic inoculations instead of proper dog laws, etc., etc. Or, again, if less credulous, he concludes that the art of medicine has no principles at all, that medicines "are for readiness, and not for propriety" (Bacon).

On the other hand, the physician who follows such methods fails to increase as he should in therapeutic experience and facility. Getting therapeutic knowledge, perhaps, but never therapeutic wisdom, he drifts along, depending more on the statements of salesmen or drummers than he does on those whose interests in drugs are chiefly in their therapeutic effects, and hardly at all on his own observations. Even if observations are carefully made and recorded, the accumulation fails because of the variety of data, as in the case of a physician I know who tried some three dozen creasote preparations in as many cases of consumption in a short time, and was unable to speak confidently of any one.

The making of new preparations and the haste to try them form a vicious circle. Synthetic drugs and mixtures were poured forth in response to the alacrity with which the first ventures in these lines were taken up. As the sick layman grasps at anything in the way of treatment, so many physicians prescribe new and untried drugs, and just as every soldier in Napoleon's armies carried a marshal's baton in his knapsack, so every assistant in a chemical factory dreams of and works for a new synthetic, and many a teacher whose ambition is supposed to be centered on "gathering pebbles on the seashore of science," is working just as hard on some similar scheme. The manufacturers gladly exploit any novelty, expecting the usual profits. The medical profession, as one of the most striking examples of the triumph of Hope over Experience, keeps on accepting the discoveries, repeating over and over the story of disappointment.

The natural tendency to believe everything, not always repressed by training, is skilfully fostered by the resources of the modern advertiser. Exaggeration is inseparable from the enthusiasm of an inventor and discoverer. Had it not been for the unproved assertion, based on perfect good faith, in the complete and permanent protection against smallpox, the use of vaccination would long have been delayed. There is some difference between the sanguine hopes of a discoverer and the studied rhetoric of an advertising expert, but the difference is not easy to see. In the case of proprietary remedies exaggerated claims of excellence at every point, assertions of freedom from the untoward effects inseparable from the action of remedies, insinuations of new properties and suggestions of the imperfection or uselessness of older remedies are all advanced with a skill born of keen competition.

Sometimes the assertions are so absurd that it would seem impossible for any one to pay further attention to the substance advertised, yet experience shows that this is not so. A few years ago a preparation was exploited which was claimed to contain live red-blood corpuscles, which latter were alleged to be capable of entering the body of the sick man and restoring it to health. The finding of the philosopher's stone, the realization of perpetual motion, or the existence of Dowie's healing power seem as easy to accept as theorems of Euclid compared with these claims. And yet this product, notwithstanding so disreputable a beginning and a later stage less daring, but just as cloudy, has become, if not the head of the corner, at least part of the basis of many a medical journal. The claims of organic iron preparations, of intestinal antiseptics, cardiac stimulants and antipyretics are almost as bad and do not require further mention.

Unfortunately, in all these claims, the manufacturers are aided by testimonials from physicians, just as dangerous as the testimonials of governors and congressmen that fill certain newspapers. The plain puff is too obvious, and pseudo-scientific articles are published often with great luxury of illustration.

The manager of one of the most iniquitous frauds ever sold once told me with honest pride that his firm never made a statement it did not believe. I was astounded at first, but in looking through the literature I found the claim was literally true. Everything necessary to exploit the material was furnished by physicians. That the information was given gratis may be a mitigating circumstance.

There is another method of furthering the use of new preparations, becoming so widespread as to suggest a conspiracy, though the growth may be merely the result of "mob suggestion." This is the vilification of critics of indiscriminate or irrational drugging. "Who is not for us is against us" seems to be the motto of drug sellers, and just as, sixty years ago, Skoda was called a therapeutic nihilist because he believed that bleeding and tartar emetic were not necessary in the treatment of people with pneumonia, so now any one who does not at once and always prescribe large and numerous doses of drugs is given the same term—and with the obvious intention of making him odious.

What are the remedies for the abuses connected with the sale of proprietary medicines and which I have imperfectly sketched in the preceding lines? To many the prospect seems hopeless. Drugs, like a mighty flood, pour out so rapidly that many are swept off their feet. Yet the situation is neither unique nor hopelessly bad. Sound, temperate Hippocratic medicine has lived through even worse phases. The physician of the sixteenth and seventeenth century had no coal-tar preparations and no sera, but he had more than 3,000 plants in his materia medica, not to mention minerals and animals of all kinds from worms to man, their organs, secretions and excretions. Medicine survived this, the richer by a few remedies of real value, and there seems no reason to fear that oblivion will overcome the less useful of the newer discoveries and permit the good ones to take admitted rank.

How to secure the really valuable new remedies is the problem now before all earnest therapeutists. Repression by force or by enactment can never serve against such a condition. The right to investigate, to discover, if wished for to patent new remedies, need not be curtailed. Authoritative bodies, governmental or otherwise, can do much to assist in determining the status of such products, but the final verdict must come from the great body of practical therapeutists, the physicians in actual charge of sick people. Such a body as the Council on Pharmacy and Chemistry of this Association may perform an important function in making impartial examinations and reports on new substances of obscure composition, but it can not determine whether or not such substances shall be used. The American Pharmacologic Society can also carry on an equally valuable work in making further tests. But no such body can be depended on to disclose all the good things and repress the bad, and just as far as it prevents the development of the spirit of responsibility and of criticism on the part of the physician will it do harm.

Medicine has never been successful when bound down by traditions, schools and authorities. It has only flourished when it made use of every resource that science or chance could bring—whether the cinchona bark of the savage, the hydrotherapy of the peasant or the synthetic compounds of the university professor—testing all things, holding fast to the good.

I shall take the liberty of discussing briefly some of the solutions for the present abuses.

One of the most general is the exclusion of advertisements of proprietary medicines, at least those of unknown composition, from medical journals. There are some good reasons why this view should receive consideration. A scientific periodical certainly makes a more pleasing impression when it is free from all advertising. In the case of journals of a more practical tendency it is convenient to be able to find advertisements of drugs, books, instruments and other supplies, but even if classified it is difficult to find what is wanted if there is a preponderating number of notices of drugs, mostly unknown. These are particularly exasperating when inserted among the pages of text, as in some of the most reputable English periodicals. On the other hand, merely keeping such advertisements out of journals would not stop the nuisance, for the same matter, or more, would be forced on us in other ways—sample copies, circulars and the like. Nor would the exclusion of such matter from journals be a likely aid to the morals of those who now fall victims to the wiles of the advertiser. In the practice of medicine, virtue that comes only from lack of temptation is as doubtful a quality as in other cases. Moreover, the daily or weekly appearance of an advertisement can not be sufficient reason for any competent person to patronize the thing advertised. Surely the readers of medical journals do not buy every carriage or automobile, or even every book, any more than they buy all the bargains advertised in the daily paper. Medicines, like get-rich-quick schemes, furnish a bait of unusual attraction, but both can be withstood.

It can hardly be expected that physicians will abandon the reading of journals with advertisements of nostrums, but if the goods advertised were not bought the obnoxious pages would soon disappear.

It would seem possible to exclude the most exaggerated or obviously baseless claims, but this is not so easy as might seem at first glance, as the following experience shows: In a recent number of the *Fortschritte der Medizin* there was a brief notice of a preparation loudly advertised in America, with a fling at the "credulous colleagues" in "the land of unbounded possibilities." Yet in the same number of the same journal, as in all the previous numbers, were many advertisements, to me just as bad, including one of a remedy for gout, sciatica, "all rheumatisms," influenza and nervous headaches, the same being also an expectorant useful in putrid bronchitis, typhoid and pneumonia, and a specific for whooping cough, asthma, cardiac neuroses and arteriosclerosis!

A decided gain would come from a freer criticism of all kinds in our medical literature. A fear of frankness seems to bind it all—in abstracts, in book reviews and in editorials. Much of this depends, no doubt, on trade affiliations, but it seems to spread beyond them. I may be permitted to cite an example: A plain and easily controllable investigation of the claims of a widely advertised mud preparation was published in The Journal of the Association at my instigation. Personal communications and letters from many physicians confirm my idea that the report was one of value. Within a few days after it appeared a circular letter was issued to medical journals, giving a misleading account (though it had been believed by the writer) of the origin of the article, and requesting editors of other journals not to abstract it. The scientific statements in the article were easy to test, and were important, no matter how the article originated. Most of the periodicals, however, followed the wishes of the advertisers and the article was conspicuous by its absence from the abstract columns of the great bulk of journals.

Incidents of this kind, for I am sure the experience mentioned is not unique, indicate one of the greatest obstacles to the freedom of medical science.

Recently a very clear-minded critic of affairs has pointed out the advantages of greater frankness on the part of physicians toward patients. I think most of us agree on this, at least in the case of intelligent patients. But is there not even greater need of frankness among ourselves, and especially of plain speaking, without cant, prejudice or passion, as regards one phase of one of the greatest evils of the day—the nostrum evil?

At best proprietary remedies will continue to be made and advertised, and all sorts of claims will be made for them. We as a profession can not directly stop these things, even if we think it desirable to do so.

We can, however, learn how to use better than we do now well-known remedies and in that way lessen the use of the others. And, although we can not draw a sharp line between unprincipled time-serving or the affectation of ultramodernity, we can at least express our opinion of crude experimentation. We can assume that the physician who depends on the remedies advertised in display type is no more deserving the credit of advanced views than one who should sell his horses or automobile and buy a balloon for making his daily calls. We can look as coolly on new drugs as we do on a new phase of mental healing or a new application of massage. If this were done, production would be less rapid, the vogue of each novelty shorter, the possible virtues of some more quickly determined.

At times, no doubt, some loss would come from this attitude, as it did from the neglect of the revelations of Holmes, Semmelweiss and Lister. Yet there would be compensations. Perhaps the loss of life from the delay of accepting asepsis was not greater than that from the indiscriminate use of coal-tar antipyretics.

How can the profession be brought to a better attitude as regards the present evil? Many think the solution is to be found in more teaching of prescription writing, of lectures on therapeutics. I differ from those who hold this view. What is needed is (1) broader and deeper training in preliminary and biologic branches and the cultivation of exact habits of mind; (2) a more intense study of pathology, not merely to acquire anatomic data, but to learn the actual results and extent of the lesions in common diseases, so that the student may offset speculation with fact; (3) a more intimate study of clinical medicine, that can only come from more prolonged and more personal investigation at the bedside.

In speaking of the evils of the nostrum habit among physicians do we not forget that, although we usually speak of the profession as a whole, the individuals vary enormously in capacity and opportunities for the study of medicine? Doubtless many graduates of hopelessly poor schools become sound and well-informed physicians, and equally doubtless some graduates of great schools fall into utter routinism, but is not the chief fault the existence of several scores of schools that never have given and never can give proper medical instruction?

To sum up, proprietary medicines are increasing as the result of natural developments. Their abuses spring partly from the exaggeration of legitimate commercial methods, partly from the credulity of the medical profession. The remedy for this part is wholly in ourselves. Let us do all we can to overcome this at least.

THE PHYSICIAN'S RESPONSIBILITY FOR THE NOSTRUM EVIL.*

RICHARD C. CABOT, M.D.
BOSTON.

As physicians we are largely responsible for the sale of secret remedies. We help to create the demand. We feed it.

We feed it because it is shown that 44 per cent. of the prescriptions filled at one of the best of our Back Bay drug stores in Boston call for nostrums—secret remedies of whose constituents we are ignorant.

The conditions are the same or worse elsewhere. The manufacturers and those whose living depends on the sale of these nostrums, have done their best to obscure the issue by vilifying the leaders of the present vigorous crusade against secret nostrums; I mean Dr. Simmons and Dr. Billings. The nostrum makers and a group of medical journals which are their organs, try to deceive us into believing that the great crusade for honest, open, intelligent prescribing and against fraud and ignorance in therapeutics, is all the work of those splendid leaders, Dr. Simmons and Dr. Billings. The truth is that almost every man of mark in the medical profession of the United States has put himself on record within the last year as being in entire accord with the policy of The Journal of the American Medical Association, and with the quite unanswerable arguments brought forward in this section by Dr. Billings a year ago. The leaders of medicine throughout the country are in accord on this matter and it is time for the rest of us lesser lights to stand up and be counted too. Any one who attacks Dr. Simmons and Dr. Billings attacks every one of the leading men in American medicine to-day. We, their followers, should stand ready to be hit, too, by every missile thrown at them, for the intelligence of the profession is solidly on the side of The Journal in this matter.

The issue is simply between light and darkness—between ignorance and knowledge. A man should know what he is prescribing and not pour down their patients' throats mixtures of whose ingredients and action he is ignorant. It is not a question of where these nostrums are advertised, or whether or not they are patented, or whether the Pharmacopeia contains or excludes them. The whole question for us is: Shall we be false to the confidence which our patients place in us? Shall we, who should safeguard their interests with the keenest watchfulness, desert our post and permit, nay advise them, to use medicine whose composition is wholly guesswork to us, though our patients trust us to investigate and to understand it?

I do not see how any honorable man can see two sides to this question. Suppose an investor went to his financial adviser for counsel on investments and was recommended to buy a certain stock. Suppose the investor to ask "What is the property? Is it manufacturing stock, railroad stock, mines, municipal enterprises?" Would he not be angry and indignant if his expert adviser should answer: "I don't know what it is. A promoter gave me some and said it was good, but I know nothing about it save what he told me." A pretty sort of adviser, this! False to his trust, surely; but we are far worse than that, for the financial adviser was dealing only with his client's property, while we deal with his life. They juggle with his dollars—we with his vital organs.

I believe there are not many in this audience who are not guilty—as I am guilty—of the sin of having used remedies—some of them dangerous—without knowing what they contained. I have used ammonol, before our Council on Pharmacy and Chemistry showed it up. I supposed (ignorantly, culpably) that it was a synthetic chemical compound, instead of an acetanilid mixture. I am ashamed of it. I shall try to do better, and never again to advise a powerful poison without knowing it, or an inert drug while supposing it, on hearsay evidence, to possess power. But that is just what is advised in 44 per cent. of the prescriptions filled in our Back Bay drug stores. If the public realized this it would be justly angry at our indolence and faithlessness in the high position of trust.

But, I believe that we not only feed the public demand for useless and harmful drugs, but also go far to create that very demand.

Babes are not born with a desire to take a drug for every symptom—they acquire this desire. Who teaches them? You and I do. We educate our patients and their friends to believe that every or almost every symptom and disease can be benefited by a drug. Some ignorant practitioners believe this, and we can not blame them, though we deplore the results of their indiscriminate drugging. But in my experience the educated physician who knows that only a few of his patients can be much benefited by drugs, gives out just as many prescriptions as the ignorant physician who believes all that the Pharmacopeia and the nostrum vendor tell him. The only difference is that the educated physician gives his drugs as placebos. In my opinion, the placebo habit does more harm than the habit of giving drugs to every patient with full faith in their pharmacologic action. But of this I shall say more in a moment. Here what I want to insist on is that so long as the chief visible, tangible, gustable result of a physician's visits is a row of medicine bottles, just so long will the patient tend to try to eliminate the middle man (the doctor) and buy the drugs himself, "patent" or pharmacopeial as the case may be.

If the result of the physician's visits were a reform in the patient's diet, a lengthening of his hours of sleep, better habits in bathing, ventilation and exercise, and a sleeping balcony, no patient would be such a fool as to think he could get these results out of a bottle of "patent medicine" or a box of headache powders; but when the net result of the doctor's expensive visits is medicine bottles, the patient learns his lesson, clings to his bottle, and eliminates the expensive visits. Result: $75,000,000 a year for secret remedies.

Placebos have another bad result. They weaken the confidence of the patient in the physician, because every placebo is a lie, and in the long run the lie is found out. We give a placebo with one meaning; the patient receives it with quite another. We mean him to suppose that the drug acts directly on his body, not through his mind by means of expectant attention. If the patient finds out what we are doing he laughs at it or is rightly angry with us. I have seen both the laughter and the anger—at our expense. Placebo giving is quackery. It also fosters the nostrum evil.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

The "patent medicine" and nostrum industry will be seriously crippled when we do two things:

(*a*) Stop advising secret remedies which may be poisonous or inert.

(*b*) Stop fooling our patients with placebos.

The positive side of all this negative advice I have tried to explain in another paper.[1]

DISCUSSION.

SYMPOSIUM ON PROPRIETARY MEDICINES.

Dr. W. S. Thayer, Baltimore, said he agreed with Dr. Cabot. He related an occurrence in the South when he attended a country medical society and talked on the subject of typhoid fever, telling them what it was, etc. After going over the question of the pathologic conditions involved he told of what one could expect from the methods of treatment and talked very plainly regarding it. He did not know that a well-known drug firm had engaged men to make speeches during a recent campaign, telling of the good of intestinal antiseptics in the treatment of typhoid fever. If the members of that society had had the training that the members of the American Medical Association had, they would have known when that man talked such arrant nonsense. Dr. Thayer said that the better education of the physicians all over the country would do much in the solving of this problem.

There was a point in which he did not agree with Dr. Dock; he could not see the advantage to be gained by admitting the possibility of physicians patenting drugs, etc., for that was not the way for the practicing physician to make money; we should have a higher aim than that. It was a mistake and was likely to lead to more harm than good. The stand should always be taken that the medical profession should not patent or acquire individual rights in the discovery of anything which had to do with the treatment of the diseases which afflicted the human being.

Dr. H. A. Hare, Philadelphia, said that he wished to raise his voice in defense of the medical profession, and if he took on himself this defense, he did it because he wished to defend himself as well. He vehemently denied the truth of any statement made that members of the medical profession, particularly of Pennsylvania and of Philadelphia, had deliberately given placebos to patients with the idea of fooling or deluding them. He said he was in accord with the statements made by Dr. Thayer, and against those made by Dr. Dock, in what was said regarding numbers of the medical profession patenting drugs or instruments. In regard to patented remedies which possess therapeutic value he believed physicians should employ them. If they did not they would be depriving themselves and their patients of remedies which the more progressive members of their calling would use. It is a mistake to turn down everything because it is patented. He said he could mention drugs employed by all of them for many years which were patented and which they could not do without, such as phenacetin.

Dr. Hare said that a surgeon could recommend an instrument and name the man who made the instrument and not be criticized for it; but if a physician wrote an article and endorsed a certain drug as being of value, even though he did not mention the name of the maker, he would be under suspicion. Dr. Hare thought there should be a normal balance in this matter and that they should give rational consideration to the therapeutic possibilities of substances presented to them.

Dr. S. Solis Cohen, Philadelphia, said he wished to emphasize some points that had not been sufficiently brought forward in the papers. Distinction must be clearly made among the various classes of proprietary remedies: 1, "Patent medicines," so called, the nostrums sold to the public through advertisements, usually full of falsehoods, like peruna, the Pinkham medicines and their kind; 2, the nostrums advertised to physicians, the secret or partly secret "proprietary," sold to the public in part directly, in part through the prescription of careless, thoughtless or deluded practitioners, such as antikamnia and its congeners; 3, the proprietary not secret, for example, Squibb's ether or Hayden's creosotal; 4, the drugs patented and therefore not secret, as antipyrin and phenacetin; 5, patented drugs tainted with fraud because not conforming to the description in the patent.

He agreed with Dr. Hare that non-fraudulent patented drugs might be used by physicians without hesitation, but there was some danger that Dr. Hare's words might be misunderstood. When Dr. Hare spoke of using "illegitimate" or "unethical" remedies he might be misconstrued as supporting the use of secret remedies; in other words, nostrums, the drugs and mixtures of which the composition was concealed. This subject was so important and the nostrum manufacturers tried so hard to render the distinction obscure that there must not be left even by inadvertence a loop hole for misconception. Referring to one speaker's *peccavi* or rather *peccabat*, Dr. Cohen did not understand how any intelligent physician could wittingly order a medicine the composition of which he did not know, but that such a mistake was in this instance honestly made did not justify an indiscriminate denunciation of all other drug-giving. What is needed is intelligent use of drugs, that is to say, the use of known drugs, under suitable conditions. Should they abandon opium or digitalis because some one may use them unnecessarily? One great fault of secret remedies is that there is no guarantee of their uniformity. The composition of "patent medicine" and other nostrums might be changed day by day and has been changed materially in well-attested instances, as shown by careful analyses. One who prescribes antikamnia, for example, has no means of knowing whether it will be the same thing or something else to-morrow.

Dr. Dock's proposition for physicians to take out patents on remedies is an unthinkable method. The cure is worse than the disease. While we might yield to necessity and as he—Dr. Cohen—had already conceded, prescribe drugs of known composition patented by their makers, yet we should not encourage such a lowering of the traditional standards of the medical profession itself. It was to be regretted that they had not taken a decided stand, as indeed he, among others, had urged at the time, and refused to prescribe patented drugs when Knorr's antipyrin was first put on the market. The general issue would have been fought out then and there, and science and humanity would have won. Nothing would have been lost to therapeutics even had the introduction of antipyrin into clinical use been long delayed. Indeed, the temptation to exploit the drug for gain would have been removed, it would not have been so widely and wildly advertised or so much imitated, and perhaps thousands and tens of thousands of lives would have been spared that were lost through its use and that of other coal-tar antipyretics in typhoid fever, pneumonia, and especially influenza. The true sphere of usefulness and, above all, the limitations of the new drugs would have been well defined. Nothing would have been lost, and much would have been gained. It is too late to return to the *status quo ante*, but they can at least preserve what is left of the traditional heritage of the physician.

Dr. Woods Hutchinson, Redlands, Cal., asked that they all look at that medical barbarism, the United States Pharmacopeia, and the enormous lists of things that had been published. Anyone looking over those lists must have been struck with the great number of drugs that have been retained, and it is the fault of the profession that such a large number was retained. The remedy lies in our hands. At least one-half the pages should be cut out; instead, somewhere in the neighborhood of 1,500 or 2,000 remedies had been added. He believed the Pharmacopeia should be revised.

Dr. Albert Francine, Philadelphia, said that he thought it was worth while to review briefly what had been accomplished by the agitation during the past few years against nostrums and proprietary medicines in relation to the general public, to the accomplishment of legislation and to the profession itself. He said that the education of the public had proceeded rapidly and that they were becoming fully alive to the dangerous character of these mixtures. This was shown practically in the fact that the sale of "patent medicines" had decreased enormously throughout the country; and was also reflected in the public press, which now published frequent accounts of poisoning from headache powders and other nostrums, recognizing that the public was interested.

---

[1] "The Renaissance of Therapeutics, "THE JOURNAL, June 2, 1906.

Success had not been so marked in regard to getting the enactment of legislation. He wished that every state could accomplish the legislation which Massachusetts had just inaugurated, by which cocain could be sold only on a doctor's prescription and could not be an ingredient of any copyright mixture whatsoever; morphin could be present only in the proportion of one-fourth gr. to the ounce of solution; and alcohol could be used only in sufficient quantity to act as a solvent. This was certainly a long step in the right direction, and must, if enforced, be the death blow to the alcoholic nostrums and to many others containing cocain and morphin.

The most interesting and difficult phase of the subject and the field for their most legitimate efforts, was in the relation of the profession to proprietary medicines. Their use by physicians appeared to be increasing rather than diminishing. This arose from two things, carelessness and ignorance. Credit must be given to the manufacturing chemist for putting out very elegant mixtures, some of them with the formula on the bottle, and for the temptation thus held out to use them. But as Dr Billings had well said: "To the rational physician, mixtures even with a known formula are objectionable, for disease is never quite the same in different individuals and never quite the same in its different stages." Dr. Francine thought that too many members of the profession did not appreciate their responsibilities in this regard. He thought that the medical schools did not do their full duty in training their graduates in the arts of pharmacology and therapeutics, and in prescription writing. Graduates did not know how to write prescriptions, how skillfully to combine drugs, and did not, as a rule, subsequently familiarize themselves with them. Every graduate, even after a term of service in a large hospital, should diligently apply himself to this study, and it was because this was not generally done that they fell back on ready-made preparations. He thought there was justification for criticism of the usual methods of teaching therapeutics in the medical schools, though this phase of it was a difficult problem for the latter to handle or adjust properly. The physiologic action of drugs and prescription writing should be taught in close relation to their clinical application. It seemed folly to teach the use and action of the nitrites to second and third-year students, when they had little or no familiarity with the diseases in which they were indicated, and yet this was the usual course. It would seem wise, if the physiologic action of drugs must be taught at that time to supplement such theoretical teaching by practical work in prescription writing and prescribing in the fourth year directly to clinical cases in the wards and dispensaries.

Dr. Louis LeRoy, Nashville, Tenn., said that the speakers were laying all of the trouble, or most of it, at the door of the practicing physician, as if he could revolutionize public opinion. He said that he had found that the attitude of the public man now was about reflected by the attitude of the medical man of some one hundred years ago; it took one hundred years to come to the attitude and it probably would take another hundred years to come to the attitude of the medical men of to-day. While they might take some decided step, he felt only moderately sanguine over diminishing to any marked extent the public use of nostrums. Another thing he said should be borne in mind: the medical student came to them in the mental attitude of the general public and in that student they must build up this work. A great thing that had been lacking so long in medical schools was common "horse sense," as well as the ability to correlate what they got. Some of this could be cultivated to a certain extent, although some never would, and some never could. He said they were at fault in medical teaching, in that they did not teach medical students how to put two and two together.

Dr. Richard C. Cabot, Boston, in answer to what was said regarding placebos, said that he would charge no man with what he had not done himself and that he had given bushels of placebos, as all doctors do, to impress the patient. But when they gave placebos they were in precisely the same attitude as the quack. They were pretending to possess remedies and powers which, in fact, they did not possess. Dr. Cabot added that placebos were lies, because if they explained to the patient that they were inert and given solely to influence his symptoms through his mind, they would then be useless. It was only when they led the patient mistakenly to suppose that these inert drugs had genuine medicinal action, that they work on his mind. They should all do as Grover Cleveland, at the last annual meeting of the Medical Society of the State of New York, entreated them to do, namely, treat their patients like intelligent human beings; be open with them, be fair with them, treat them as they would want to be treated if they were sick.

Dr. George Dock, Ann Arbor, Mich., said that he would limit his remarks to the question of patients. He was prepared for the objections made against the patenting of medical inventions, and, in fact, expected even greater objections. He had at one time shared the views so clearly stated by Dr. Thayer. He thought that conditions had somewhat changed and that the objection to the patenting or dispensing of a secret preparation could not apply to the patenting of a discovery or invention of a new principle. A good deal has been said about the fact that Jenner did not take out a patent on vaccination. It would have been a great deal better for vaccination if Jenner had. He himself complained of the harm that was done by careless and ignorant vaccinators. If he had been able to control the standard of vaccine and the method of vaccinating for a few years, the result might have been very much better. A patent made the material public, or open, so far as its composition was concerned. He thought it was unfortunate that in this country they were able to patent the product. It would be very much better if the right were limited to patenting the process. Invention would be stimulated in still further perfecting the product. If a physician did not wish to take money derived from the patent of an invention it would be an easy thing to forego his royalties. On the other hand, if it is wrong to take out a patent on a remedial agent it would seem to be equally wrong to use the patented article. Dr. Dock said that he had not used ammonol, but confessed to having used Behring's antitoxin, adrenalin and modified milk, all of which he was informed were patented. He did not believe that these would have been any worse if patents had been held by physicians.

CIRRHOTIC CHANGES IN THE LIVER FOLLOWING A SINGLE INJURY.*

W. G. MacCallum, M.D.
Associate Professor of Pathology, Johns Hopkins University.
BALTIMORE.

It is well known that various poisonous materials circulating in the blood may cause the destruction of the cells of the liver, sometimes in very small foci, sometimes much more diffusely throughout the whole organ. In many cases, as has been emphasized by Opie, this destruction may occur fairly regularly in certain portions or zones of the lobule, while in other cases it is difficult to determine any such regularity.

Necroses of similar type may be produced experimentally, as shown by Pearce and others, but they most commonly occur in the course of acute infections and intoxications. When limited in extent they may destroy so little of the liver that no definite symptoms result and the injured area is in time replaced by scar tissue, the remaining liver tissue becoming hypertrophied to compensate for that which was lost. This process may become a more or less continuous one if the source of the poison persists, and the final result of such repeated injuries and healings is one or other of the varieties of cirrhosis of the liver. The changes involved in this I have discussed in detail in a previous paper.[1]

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

When the injury to the liver tissue is very extensive and involves at one time the greater part of the liver, symptoms at once arise, and such a condition which is commonly classed as acute yellow atrophy may quickly bring about the death of the patient. Recovery sometimes occurs, and the reparatory changes in the liver in such cases have been minutely studied. One case of this kind was reported in detail,[2] and since that time another case has come to my notice. This second case was that of a child who died of peritonitis following appendicitis, but who had otherwise always been well except for an attack of scarlet fever some months before. At autopsy the liver was found to be extraordinarily distorted by the presence of large prominent nodules of grayish, swollen-looking liver substance, each surrounding a central branch of the portal vein. Between these masses the tissue was shrunken and fibrous and dark grayish red in color. Microscopically there were found conditions entirely analogous to those described in the published case, i. e., in many areas the collapsed scarred framework of the liver with proliferating sprouts from the bile ducts; in other places the greatly enlarged liver lobules which had resulted from the hypertrophy of those lobules which remained uninjured.

The aim of this note is merely to show what must be almost obvious, that there may occur a scarred condition of the liver perhaps intermediate between the ordinary cirrhosis and the extraordinary distortion just described, a condition, in other words, in which some single attack of an infectious disease or some single intoxication has produced a single non-progressive, though widespread, injury from which complete and permanent recovery has occurred.

Such livers present, in general, a smooth, even surface, interrupted only by a network of fine linear grooves, which are also seen on section and which indicate the places where destruction of the liver cells took place. The remaining tissue in two cases which we have studied was composed of lobules perfectly normal in form, but rather larger than the normal. Microscopically, but little proliferative change in the bile ducts are to be observed, and it appeared, indeed, that in these cases but little definite scar tissue had appeared, the depressed lines being composed of atrophic and collapsed liver tissue in which the blood capillaries were separated by scale-like remains of liver cells only.

Similar conditions have been observed in a case of pernicious anemia and in a case of myelocytic leukemia in which the livers were found to present, evidently as the result of a single injury, ramifying bands and lines in which the epithelial cells had been destroyed so that the framework of the tissue had collapsed into a red, vascular, spongy substance, while the remaining uninjured liver tissue stood out prominently in the form of opaque, yellowish-gray masses, with normal or somewhat enlarged lobulations.

These are rather extreme cases, but there are many cases in which, although no symptoms referable to the liver were noted during life, the autopsy revealed a liver practically normal, except for the presence of irregular, fine lines of scar tissue throughout its substance. These are commonly recognized as cases of incipient cirrhosis, and, indeed, it can not be denied that they are cases of cirrhosis, but we have no evidence whatever that the condition is part of a progressive process. From the normal state of most of the liver tissue it seems far more probable that we are dealing, not with the beginning of an advancing cirrhosis of the liver, but rather with a finished or stationary condition which has existed unchanged, since the injuries to the liver produced in the course of an attack of some infectious disease in earlier life were permanently healed. In other words, the condition differs from ordinary cirrhosis merely in not being progressive and in representing only the scars of an old injury.

DISCUSSION.

Dr. W. Ophüls, San Francisco, believed with Dr. MacCallum that the importance of the regenerative and reparatory changes taking place in cirrhosis can not very well be exaggerated, but he would not go so far in giving the interstitial changes an entirely secondary position. His contention is based very largely on some experiments which he has been doing on chronic nephritis. For his experiments he used guinea-pigs and dogs, feeding them certain well-known poisonous substances which affect the kidneys, and the specimens show that, although there are degenerative changes with the interstitial processes which were observed, they are hardly marked enough to be regarded as primary, nor is there any direct local relation between the two, the degenerative changes being diffuse in character and the inflammatory changes being localized in certain parts. It is certainly true that in these chronic inflammations degenerative and reparatory changes in the epithelium play a very important rôle in the production of the anatomic picture.

Dr. Henry A. Christian, Boston, asked Dr. MacCallum what in these lesions he considered the possible determining feature of the attack on the periphery of the lobule in the light of the fact that most acute conditions attack the center of the lobule. Such, at least, had been the distribution of acute necroses in his cases. He also asked what Dr. MacCallum thought about the endothelial type of cell which appears, that is, the cell which morphologically resembles an endothelial cell; whether he regards such cells as true endothelial cells.

Dr. MacCallum said that he was convinced that the only instance of primary trouble is of the highly organized tissues. He can not make clear himself any constricting effect on the liver tissue. In regard to Dr. Christian's remarks, he thought that necrosis of the liver is different in arrangement at Baltimore from what it is in Boston. He has been struck by the relative rarity of the central lesions. As to Dr. Christian's second question, he does not regard these as endothelial cells or that they go to the formation of any blood vessels.

Dr. Henry A. Christian, Boston, agreed that what Dr. MacCallum said about the difference between Boston and Baltimore is true. This was brought out when Dr. Opie read his paper in Washington on "Zonal Necroses of the Liver." Dr. Christian said that he felt rather badly because he thought that this condition might have been overlooked in Boston, but he came back and went over something like 2,000 cases and found only central necroses. He can not explain why this difference exists. The types of cirrhosis in Baltimore and Boston are practically the same.

Electric Signal for Wet Diapers.—We learn from an exchange that the Exhibition of Hygiene recently held at Vienna contained a practical device, the invention of Professor Pfaundler, to aid in the care of infants. It is an electric contrivance with dry elements and a small wire pad. The latter is placed in the child's diaper. As soon as the diaper becomes wet the circuit is closed and an electric bell rings until dry conditions are restored.

A PLEA FOR MORE RADICAL OPERATIONS IN CANCER OF THE LIPS AND TONGUE.*

D. N. EISENDRATH, M.D.
CHICAGO.

The decreased number of recurrences after a thorough removal of the breast according to the method of Halsted and others has taught us that the same principles could be applied in the surgical treatment of carcinomata elsewhere in the body. In no class of cases does this seem more promising than in carcinomata of the more superficial character like those of the face, tongue, lips, ear, etc.

MODE OF GROWTH OF SQUAMOUS-CELLED CARCINOMATA.

Carcinomata of the lips, tongue, ear, etc., all belong to the flat or squamous-celled type. They spread almost exclusively either by continuity of tissue or along the lymphatic spaces and vessels to the lymph nodes which normally drain the region involved. Metastatic growths in the internal viscera or long bones are very rare in the squamous-celled type of carcinoma.

von Winiwarter and Landau were unable to find internal metastases in a large number of cases examined by them. Küttner[1] found only four in which there were such deposits in a number of cases of cancer of the tongue reported from nine German university clinics.

These data confirm the frequently observed clinical fact that recurrence of carcinoma of the lips, tongue, etc., usually takes place close to the original seat of operation or in the adjacent lymph nodes. Such a local or regional recurrence usually manifests itself from one to three years after operation; but cases have been reported in which they did not appear for eight or ten years. The latter are a rare exception.

There are but few reliable statistics which will aid us in judging of the percentage of permanent recovery after the older and less radical operations for removal of the class of carcinomata of which this paper treats. The chief reason for this is the great difficulty in following the cases for a long period. Küttner was able to collect 162 cases from nine hospitals in which the nonradical operation had been performed for cancer of the tongue and found only 13 per cent. of permanent recoveries.

There is no form of carcinoma in which involvement of the lymph nodes draining the area involved takes place as early as in carcinoma of the tongue, lips, etc. It is for this reason that operations for the radical removal of all infected territory seem to offer such favorable opportunities for permanent cures.

LYMPH NODES WHICH DRAIN THE LIPS, TONGUE, FACE AND EARS.

These have been carefully investigated by Sappey, Küttner,[1] Polya,[2] Poirier[3] and others and can be best understood by a reference to Figures 1, 2 and 3. They are as follows:

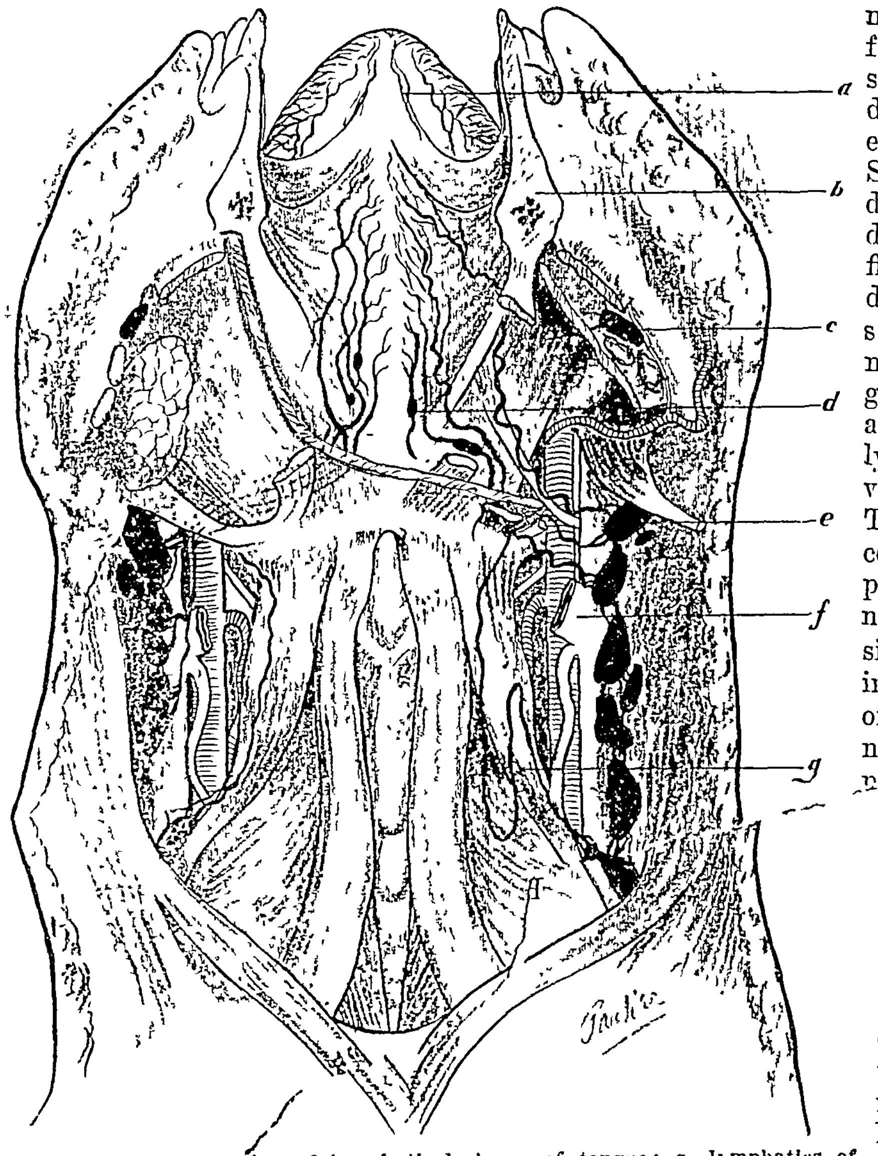

Fig. 1.—Anterior view of lymphatic drainage of tongue; *a*, lymphatics of sides of tongue and floor of mouth; *b*, cut surface of jaw divided in the median line; *c*, submaxillary lymph node; *d*, lymph nodes in geniohyoid muscle; *e*, deep cervical node along the internal jugular vein; *f*, internal jugular vein; *g*, omohyoid muscle.

1. For the Tongue (*Fig. 1*).—Submaxillary lymph nodes receive lymph from the edge, lower surface and middle of dorsum of tongue and entire floor of mouth. Superior and inferior deep cervical nodes drain entire tongue and floor of mouth. In addition to these there are some intramuscular nodes situated in the geniohyoid muscles, and at times retrograde lymph currents may involve the parotid nodes. There is much intercommunication of lymphatics so that a carcinoma involving only one side of the tongue may invade the lymph nodes of both sides of the neck. The most important node is situated at the bifurcation of the common carotid arteries. This node lies deep beneath the posterior belly of the digastric muscle. In order thoroughly to remove the deep nodes which drain the tongue, it is also necessary to excise the lower part of the parotid salivary gland.

2. For the Lips (*Fig. 2.*)—The chief lymph nodes which drain the lips are situated in the submental and submaxillary regions. Occasionally infection of one of the deep cervical nodes will take place at an early period. The submental lymph nodes draining the lips are situated just beneath the skin between the two anterior bellies of the digastric muscles. The submaxillary nodes lie embedded in the subcutaneous fat of this region in close relation to the capsule of the submaxillary salivary gland. They are at times found within the latter so that it is always safer to remove the submaxillary salivary gland itself.

[2] Polya: Deutsch. Ztschr. f. Chir., vol. lxv.

[3] Poirier, Cuneo and Lamere: "The Lymphatics."

Involvement of the deep cervical nodes does not take place until a later period of the primary growth, but in a radical operation, even at an early stage, the possibility of their involvement must be borne in mind.

3. *For the Ear* (*Fig. 3*).—The lymph nodes draining the external ear are chiefly the deep cervical, although at times the parotid and mastoid nodes may be first affected.

4. *For the Nose, Face and Cheeks.*—The lymphatic drainage of the nose, face and cheeks is chiefly into the submental and submaxillary nodes and from these into the deep cervical at a comparatively late period of the development of the primary growth. The lymph from the lateral portion of the face drains into the parotid nodes situated on, within and beneath the capsule of the parotid salivary gland.

One can not in general rely on any one set of nodes being affected, but must remove all of them in order to be thorough. One should not depend on external palpation for enlarged lymph nodes before undertaking a radical operation. Such enlargement may be simply inflammatory or there may be a number of deep nodes which are not palpable.

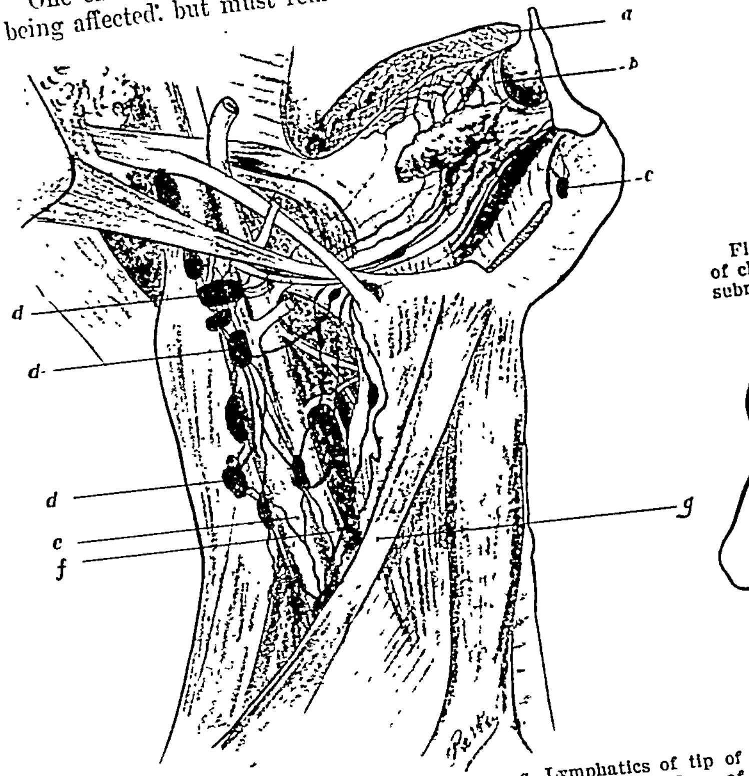

Fig. 2.—Lymph nodes draining tongue: *a*, Lymphatics of tip of the tongue; *b*, lymphatic trunks of sides of tongue and floor of mouth, draining into *c*, submaxillary and submental nodes, and into *d*, deep cervical nodes; *e*, internal jugular vein; *f*, common carotid artery; *g*, omohyoid muscle.

HISTORY OF OPERATION.

Before beginning the description of the methods I will refer briefly to the development of this tendency toward more radical operations in this class of carcinomata.

The majority of the articles have appeared during the past eight years. The first surgeon to advocate thorough removal of all lymphatic nodes was Butlin.[4] In a paper published in 1898, he stated that he had employed the method since 1895, in a more or less systematic manner, for cancer of the tongue. Since 1898 a number of articles have appeared advocating the same procedure for cancer of the tongue, lips, etc. Among these may be mentioned those of Crile, Küttner,[1] Polya,[2] Stewart,[5] Cheyne,[6] Stieda,[7] Ebel,[8] Boyd and Unwin[9] and Whitehead.[10]

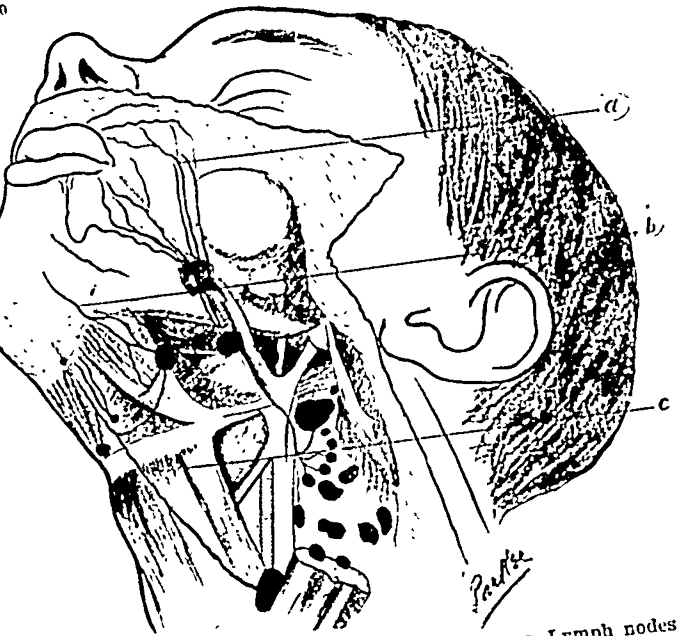

Fig. 3.—Lymph nodes draining cheeks and lips: *a*, Lymph nodes of cheek; *b*, lymph nodes of lower lip and chin region draining into submaxillary and submental glands; *c*, deep cervical nodes.

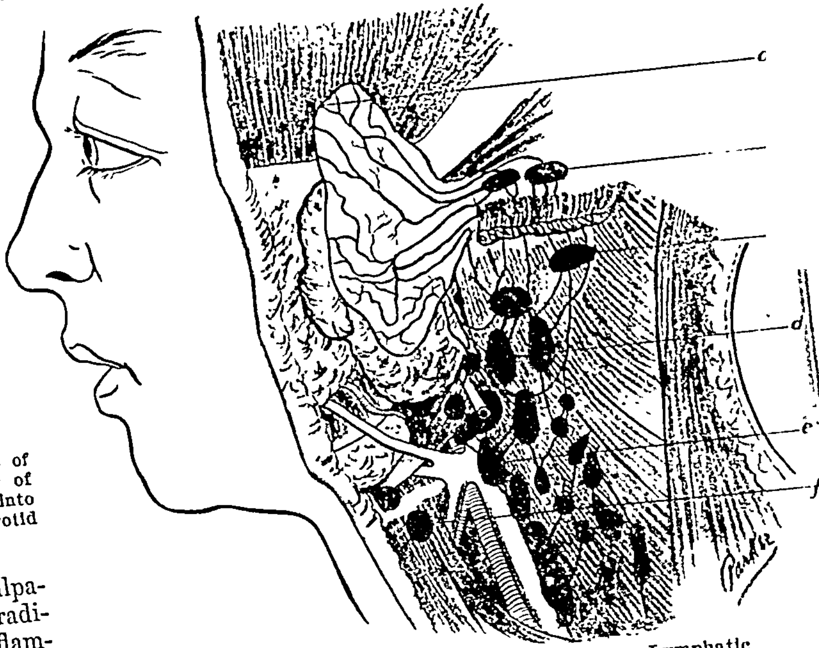

Fig. 4.—Lymph nodes draining ear (Poirier); *a*, Lymphatic trunks of auricle; *b*, mastoid, *c*, *d*, *e*, and *f*, deep cervical nodes.

Unfortunately there are but few statistics up to the present time which will enable one to form an opinion as to what extent these more radical operations have lessened the percentage of recurrence. As in the case of the development of the same mode of operation in cancers of the breast, it will be necessary to collect a large number of cases and await a considerable time after operation before we can judge of the value of the same principle as applied to cancers of the lips, tongue, etc. It would seem as though a period of at least three years should elapse before results could be fairly judged.

[8] Ebel: Beitr. z. Klin. Chir., vol. xl.
[9] Boyd and Unwin: Practitioner, May, 1903.
[10] Whitehead, W.: Practitioner, May, 1903.

Butlin[4] began to perform the operation for the complete removal of the contents of the anterior triangle of the neck in December, 1895, or January, 1896. Between that period and December, 1901, there were 28 of these operations, and, in a paper published in 1905, he says: "I will merely take the number of persons who died of affection of the gland without recurrence in the mouth and the number of successful cases, that is, of persons who were alive and well three or more years after the operation, or who died of some other disease than cancer more than three years after the operation. There were 28 cases of removal of the contents of the anterior triangle of the neck from January, 1896, to December, 1901; 4 patients died of affection of glands without recurrence in the mouth; successful cases, 10.

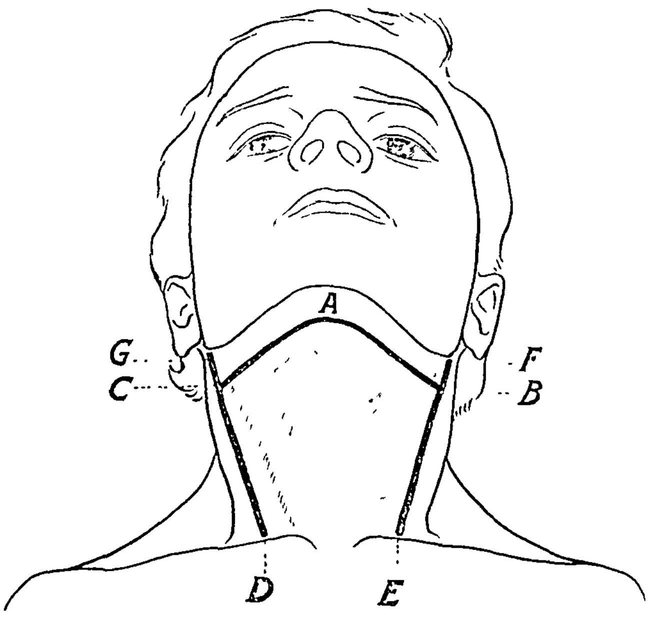

Fig. 5.—Incision employed in extirpation of lymph nodes in carcinoma of the lips, tongue, etc. C, A, B, transverse incision parallel to lower border of lower jaw, and midway between upper border of thyroid and lower jaw for extirpation of submaxillary and submental glands; G, C, D and F, B, E, incisions over middle of sternocleidomastoid muscles to permit extirpation of deep cervical nodes, with or without the removal of the sternocleidomastoid and internal jugular vein. The nodes in the supraclavicular region may be removed by an incision parallel to the upper border of the clavicle, carried outwards from D or E respectively.

Compare with these the results of the old operation, in which the glands which could be felt to be enlarged were taken out, but no more than this was done. Up to January, 1896, I performed this operation 31 times. Of these 31 cases of removal of enlarged glands before January, 1896, 8 *patients died of affection of glands* without recurrence in the mouth; successful cases, 5.

Again, take another series of cases to compare with the first series. Between January, 1896, and December, 1901, Butlin operated on 34 patients for the removal of cancer of the tongue without removal of the glands of the neck. Of these 34 cases 9 patients died of affection of the glands *without recurrence in the mouth; successful* ones, 9."

It will be seen at a glance that by far the most successful results are those which were procured by the removal of the contents of the anterior triangle. But the mere statement of numbers does not tell anything. Allowance has been made for certain conditions which were present or which were absent in each of these three series of cases. In the first series of cases, there were 18 patients in whom the glands were perceptible to touch at the time they were removed, 7 in whom they were not perceptible, and 3 of whom there was no note on this important point. By far the best results were obtained in the 7 cases in which the glands were not perceptible to touch. For 4 of these patients are among the 10 successful cases. Of course, *in the second series the glands were* perceptible in every one of the 31 patients, and that was why they were removed. So far from thinking the results bad, he was surprised to find they were so good. For it is a remarkable circumstance that five persons, under such conditions, should have been cured by so incomplete an operation. In more than 1 of these 5 cases the glands were proved *by microscopic examination to* contain epithelioma. Yet one of these patients was alive and well nearly twenty years after the operation.

Probably no corrections are required in the third series of 34 cases. For if, on the one hand, it may be said that these 34 cases comprise the lightest and most favorable of all the cases (which is, of course, true), *there were, on the other hand, some of them in which* the glands were not removed, because they were beyond reach of removal, and the operation on the tongue was merely palliative.

In 1903 I began to employ the radical removal of the lymphatic nodes and surrounding tissues in the submaxillary triangle and along the internal jugular vein *as a routine procedure in cancer of the lips, tongue, ear* and face. The number of cases is still too small and the time which has elapsed too short to render a publication of results advisable at the present time, so that the present article is intended more as a preliminary communication to call the attention of the profession to a much-needed change in our surgical treatment of these more superficially situated carcinomata.

The method employed at the present time by the majority of surgeons varies chiefly, *a*, as to the incision; *b*, as to the amount of tissue to be removed; *c*, as to whether the operation shall be performed at one or two sittings. It is necessary to divide the cases into two classes: first, those in which the case is seen by the surgeon at a *comparatively early stage* of the lymph node involvement; second, those seen at a later period when the secondary growths are very extensive. For the former the first method of operation to be described is to be employed; for the more advanced cases *the methods* recommended by Crile, Butlin[4] and others are to be used.

TECHNIC FOR LESS ADVANCED CASES.

1. *Removal of Primary Growth.*—In cancers of the lips and tongue the amount to be removed varies, of course, with the extent of the lesion. As a general rule, one should never be content with excising at least a half inch of healthy tissue on each side of the growth. In cancer of the tongue which extends beyond the median line, it is better to remove the entire organ, since the lymphatics of both sides of the neck are probably involved. Whether the tongue shall be removed, *a*, through the mouth after the method of Whitehead; or, *b*, through an incision parallel to the lower jaw, i. e., from below, combined with temporary resection of the jaw, is a matter of individual preference. The majority of surgeons both in this country and abroad prefer the Kocher

method, i. e., from below the jaw. It can be readily combined with radical removal of infected lymphatic tissue, or combined with ligation of the external carotid artery to be referred to below.

Temporary resection of the lower jaw in the median line after the method of Langenbeck adds greatly to the exposure of the operative field.

2. Removal of Infected Lymphatic Nodes.—In the majority of cases cancer of the lips, tongue, ear, face and cheek, the incisions shown in Figures 5 and 7 will suffice. I have used them since 1903 and they give excellent access to every part of the neck. In cases of cancer of the lips only the first portion need be employed; viz., C, A, B (Fig. 5). This consists of an incision through the skin and subcutaneous fat extending parallel to the lower jaw and midway between the lower border of the latter and the upper border of the thyroid cartilage from the sternocleidomastoid muscle on one side of the neck to the same structure on the opposite side.

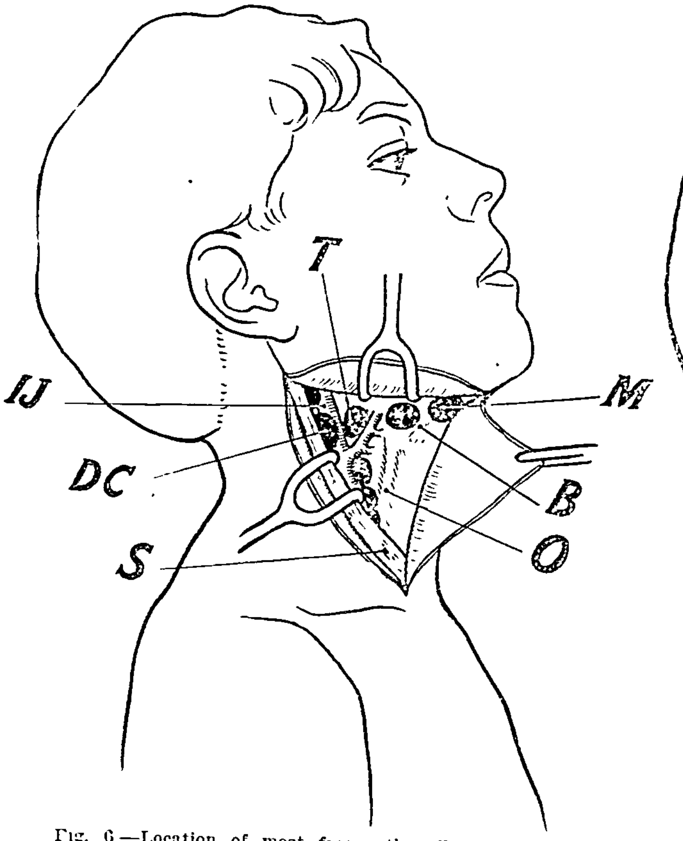

Fig. 6—Location of most frequently affected lymph nodes in carcinoma of the tongue: M, submaxillary nodes; T, deep cervical node lying between internal and anterior jugular veins; D, C, deep cervical nodes lying in front and behind internal jugular vein; S, sternocleidomastoid muscle, retracted so as to show the deep cervical nodes in the upper half of the neck; I, J, internal jugular vein; O, omohyoid muscle; B, anterior belly of digastric.

The flaps are retracted and all of the following tissues removed in submental region and the submaxillary triangles on both sides of the neck: subcutaneous fat, submaxillary and submental lymph nodes, submaxillary salivary glands and all veins, large or small.

In cases of cancer of the tongue the removal of lymphatic nodes, etc., should not only include the contents of the submaxillary region, but the additional incisions (G,C,D and F,B,E), shown in Figures 5, 6, and 7 should be made. These permit free exposure of the lymph nodes lying along the internal and anterior jugular veins beneath the sternocleidomastoid muscles on both sides of the neck and many lymph nodes between the sternocleidomastoid muscle and the muscles of the larynx and at the bifurcation of the common carotid.

If the sternomastoid or the omohyoid be involved, they should be removed, since their extirpation does not interfere greatly with the movements of the head. Similarly if the nodes are adherent to the internal jugular it is best to resect a portion of this vessel. No operation should be considered complete without a thorough removal (through the incisions made over the middle of the sternocleidomastoid muscle) of the deep cervical nodes along the internal jugular. The exposure of the supraclavicular fossæ on each side through an incision parallel to the upper portion of the clavicle (Fig. 6) permits an inspection of the lymphatics in this region and removal of the abundant fatty tissue and infected lymphatics. In cases of cancer of the tongue there are two other places in which search should always be made for infected lymph nodes. These are on and within the parotid capsule.

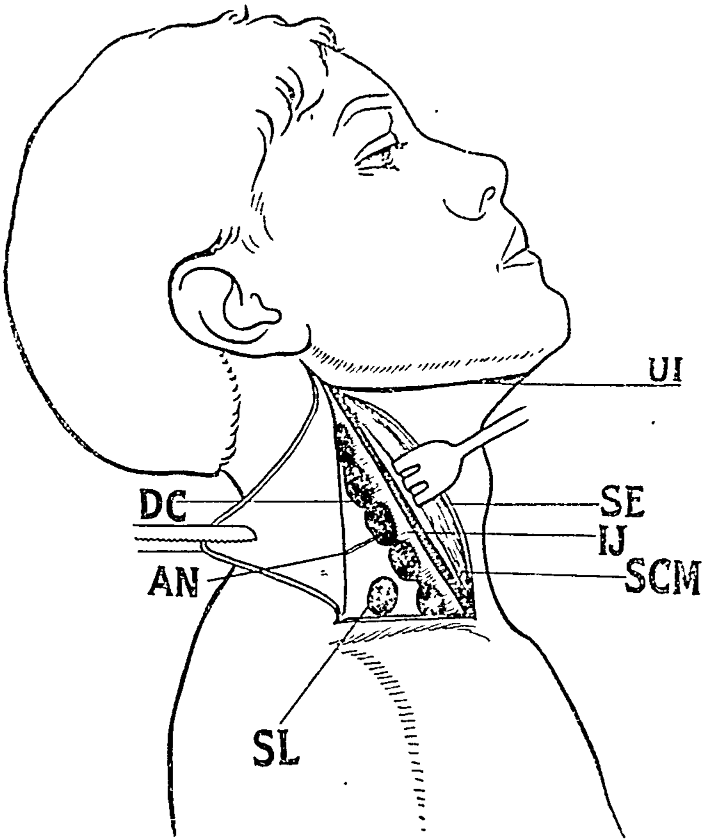

Fig. 7.—Method of removing lymph nodes in posterior triangle of neck, and those adherent to posterior aspect of internal jugular vein without resection of the sternocleidomastoid muscle: U, I, incision through which the submaxillary and submental glands have been removed; S, E, skin edge; I, J, internal jugular vein; S, C, M, sternocleidomastoid muscle pulled forward; S, L, supraclavicular nodes; A, N, spinal accessory nerve; D, C, deep cervical of internal jugular nodes.

3. Hemostasis.—Hemostasis in operations for extirpation of cancer of the lips and of the lymphatic nodes in the submaxillary region is a much simpler problem than in the case of an operation for cancer of the tongue. In the latter the question depends again on whether the organ is removed through the mouth or from below by Kocher's method. In the latter case the incisions described above for the removal of lymphatics greatly facilitate the ligation of the lingual or even of the external carotid arteries. There is, of course, some danger of cerebral embolism following the ligation of the external or common carotid. Mortality from this cause is estimated by Crile usually at from 1 to 2 per cent., but at the time of life at which cancer is likely to develop the danger of embolism from this cause increases to from 20 to 30 per cent. A ligation of the lingual arteries through the neck incision before removing the tongue is especially to be recommended as greatly decreasing the amount of hemorrhage and not being followed by embolism. In general it may be said that every vessel should be caught with artery forceps and ligated lest they reopen after the clots become dislodged.

Every precaution should be taken to avoid infecting the field of operation either from the primary growth or through careless removal of carcinomatous lymph nodes. The primary focus should be cauterized, if possible, and great care taken not to open the lymph nodes during their removal.

4. Mode of Anesthesia, Posture, Etc.—The mode of anesthesia varies according to whether or not a preliminary tracheotomy has been performed. If the latter has been done, the anesthetic is given through the canula in the trachea. If no tracheotomy has been performed one can use the method of Crile, viz., inserting a rubber tube through each nostril extending to the level of the epiglottis, or the anesthetic can be administered through the nostrils after being poured on a sponge or pumped through a rubber tube inserted just beyond the external nares with the aid of the modified Brophy apparatus. Chloroform should be given preference on account of the greatly increased amount of salivary secretion after the use of ether. The hypodermic administration of ¼ gr. morphin 15 minutes before beginning the operation greatly decreases the amount of anesthetic used.

The best position for thorough removal of the tongue with removal of the lymphatics is with a sand bag under the shoulders and the head thrown well back. Whitehead prefers a sitting posture. In operation on the lips the primary growth can be excised with the head elevated, and then the latter can be lowered to permit removal of the lymph nodes.

TECHNIC IN ADVANCED CASES.

This has been so well described by Crile in a number of recent articles that it will be necessary to refer only briefly to it here.

In these advanced cases Crile closes the common carotids temporarily by means of a clamp and then proceeds to remove from below upward all of the soft tissues, including the lymph nodes themselves, the sternocleidomastoid muscles, the internal jugular vein, fat, etc. It is remarkable how little general or local disturbance such radical procedures cause. Whitehead mentions having excised portions of the common carotids in two cases.

SHALL THE OPERATION BE PERFORMED IN ONE OR TWO SITTINGS?

The question arises in these radical operations whether both the primary growth and the lymphatics shall be removed at one sitting. The answer is that it depends. *a*, on the general condition of the patient; *b*, on the extent of involvement; *c*, on the skill and experience of the operator in this class of cases.

In cancer of the lips both operations can usually be performed at one sitting. In cancer of the tongue there should be only one sitting unless the patient's condition is such as to permit of an operation requiring in the most experienced hands from 1 to 1½ hours. The shock from these operations is, as a rule, very slight, so that, if possible, both had better be performed at the same time.

Boyd and Unwin[9] have called attention to a very important fact, viz., that if the tongue growth is removed *at the first sitting* and then the lymphatics taken out 1 to 2 weeks later an increased lymph stream follows and the tumor cells are more widely diffused. They advise, if the operation is to be performed in two steps, to remove the glands first and the tongue a week later.

It may be said in general that, with the exception of very old or weak patients, there are many advantages in performing both operations at one sitting, especially if the Kocher method of removing the tongue be employed. Butlin[4] performs the operation on the tongue first. The removal of lymphatics is done as soon as the patient is able to take food by mouth, i. e., liquid food enough to enable him to fight through the second operation.

My own method has been to perform both operations for cancer of the lips, face and ears at the same sitting. In cancer of the tongue I have carried out both at the same sitting in fairly robust patients without much glandular involvement. If the latter is extensive it is better to follow the plan of Butlin just mentioned.

103 State Street.

THE RADICAL CURE OF ANEURISM.

PRESENT STATUS OF THE METHOD OF INTRASACCULAR SUTURE, OR ENDOANEURISMORRHAPHY.*

RUDOLPH MATAS, M.D.
Professor of Surgery, Medical Department Tulane University, Louisiana.
NEW ORLEANS.

SYNOPSIS.

The term, endoaneurismorraphy, meaning the closure of an aneurismal orifice connecting the trunk of an artery with the aneurismal sac by suturing the orifice from *within* the sac and the obliteration of the sac by suture, I introduced in 1902, in a paper read before the American Surgical Association at its meeting in Albany, to describe an operation which it was my fortune to apply for the first time at the Charity Hospital of New Orleans while attempting the extirpation of a traumatic brachial aneurism in a negro, March 30, 1888, eighteen years ago. It was after the failure to cure this traumatic aneurism by the application of a proximal and distal ligature of the brachial artery that I attempted the extirpation of the sac; but the extirpation had to be abandoned because of the danger of injuring the median and ulnar nerves which were incorporated in the walls of the sac. The persistence of bleeding, after the removal of the tourniquet, from numerous collaterals which opened into the main trunk at each end of the sac, compelled me to adopt the suture with needle and silk to occlude the bleeding orifices. This simple expedient, suggested by the urgent hemostatic necessities of the case, appeared to be so easy and satisfactory that it seemed to me that any surgeon similarly situated, would have instinctively adopted this way of extricating himself from what would otherwise have been a difficult situation.

The detailed report of this case[1] attracted no notice, and it was not until after my report[2] of four additional cases of aneurism treated by this method, in which the technic of the operation, as a systematic procedure, was fully described, that the value of the suture, methodically applied to the cure of aneurism, began to be realized, and the interest of other operators roused in the subject.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[1] Medical News, Philadelphia, Oct. 27, 1888.

From June, 1902, the date of my first communication, to April, 1905, when the status of the operation was summarized,[3] I was able to present the reports of fifteen operations for aneurism performed by thirteen different operators who had adopted the method I had described. These fifteen cases, with my original five personal operations, summed up a total of twenty aneurisms treated by the method of intrasaccular suture up to April, 1905. In my second report[4] I was able to add ten more cases, from various sources, to the list, thus making a total of thirty, reported up to January, 1906.

I am now able to add six more operations to the record, four of which are of American origin and two foreign (Le Fort and Del Conte), which can not be recognized as typical procedures, such as I have described for this operation, though they are instances of the suture as applied to the closure of arterial orifices in aneurisms.

Very recently, I have learned through the program of the International Medical Congress, held in Lisbon, March, 1906, that Prof. R. Lozano, of Saragossa, Spain, has adopted my suggestions and operated on four aneurisms by arteriorrhaphy, including in this an abdominal aortic aneurism, one subclavian and two popliteals. This would swell the list of aneurisms treated by the method of suture to forty, including in this thirty-four cases reported by American operators who have adopted the procedure which I originally suggested, and six others reported by three foreign surgeons, two of whom have operated on two patients, by methods of their own, in which, however, the essential principle of suture is recognized.

With a list of thirty-four American cases thus far reported, which may later on be increased to forty when the details of these foreign cases are better known, we will soon be in a position to institute a fair comparison with other surgical methods of treating aneurisms, notably with (1) the ligature, (2) the method of Antyllus, (3) the method of Purmann, or Phylagrius, and (4) the more recent modification of the old operation suggested by the late lamented von Mikulicz.

The mere summary of the facts already gathered from the thirty-four American cases thus far reported is, I believe, sufficiently demonstrative to prove that the new method of intrasaccular suture has not only stood the test of experience, but that in all suitable cases it will accomplish, with greater certainty and simplicity, all that the older classical methods just referred to, have done and can do, for the cure of all aneurisms that are amenable to direct surgical intervention.

Before submitting a brief analysis of the reported cases I deem it necessary to explain, for the benefit of those who have not had access to my previous writings, what I mean by the cure of aneurism by the method of suture, or endoaneurismorrhaphy.

I will have to repeat here what I have recently had to state elsewhere, that "In spite of my efforts to elucidate the essential principles of the operation, and to simplify the *modus operandi*, a great deal of confusion and misapprehension still exists in the minds of many practitioners and surgeons who, having obtained their information from abstracts and second-hand descriptions given in journals and even text-books, regard it as a difficult and complicated procedure, necessarily restricted to a small group of cases which I have described as suitable for arterioplasty," or, as I shall classify them in this article, under the head of "reconstructive endoaneurismorrhaphy."

It is evident that the ideas entertained abroad on this subject are very confused. Höpfner,[5] in his notable article of 1903, classified my cases with a group of normal arteriorrhaphies, and the latest German writer on aneurism, Otto von Frisch,[6] of von Bergmann's clinic, indulges in commentaries and criticisms of an operation which he evidently does not understand, and about which he has certainly not been correctly informed. Del Conte, of Naples, in dealing with this subject, also labors under a serious misapprehension as to the essential features of the operation. The idea that prevails abroad is that the operation which Bullock, of Lexington, Ky., first associated with my name, is essentially the "formation of a new artery from an aneurismal sac by suturing, after laying open the aneurism and turning out the clot." This is not at all surprising when we consider that this idea largely prevails in this country and that the few foreigners who have paid any attention to this subject have formed their conception of the procedure on the current interpretation given of it in our own periodical literature.

Such misconceptions of the method of intrasaccular suture, demand rectification in order that the operation may not be divested of its chief merit, as a simple and thoroughly practical measure applicable to the vast majority of cases in which the ligature and methods of incision and extirpation are still currently applied, as preferred methods. The errors that I wish to correct more especially are: (1) the belief that this method of intrasaccular suture is a technically difficult procedure; (2) that arterioplasty, or the reconstruction of an artery out of the sac walls (reconstructive endoaneurismorrhaphy) is the essential and necessary feature of the operation, whereas, in reality it is only a secondary variation or development of the fundamental procedure, shortly to be described, and is applicable only to a limited number of fusiform aneurisms. In fact it is a question, which we are now trying to answer, in what particular class of aneurisms arterioplasty is necessary or especially indicated. The bolder, more aggressive idea, that of arterioplasty, has clung tenaciously to the minds of superficial readers and reviewers, and the less striking but more generally applicable arteriorrhaphy as applied to fusiform and sacciform aneurisms, has been overlooked and ignored. It should be especially remembered that the general utility of the intrasaccular suture method, as I have understood it, depends on the ease and certainty with which the aneurismal orifices can be sutured and closed without interfering with the collateral circulation, much more than on the principle of reconstructing an artery.[7]

[7] In 1902, when my experience was limited to four personal observations, I felt that there were probably numerous cases of aneurism of the lower extremities, with edematous, cyanotic and choked limbs, in which the reconstruction of the lost artery would be necessary for the preservation of the limb. Subsequent experience with nineteen popliteal and eleven femoral aneurisms in which obliterative aneurismorrhaphy has been performed in the majority of cases, has convinced me that the cases of aneurism which demand the reconstruction of the blood vessels must be few indeed, and that the obliterative and restorative modes of intrasaccular suture, by preserving the collateral circulation undisturbed, are capable of meeting safely and efficiently all the exigencies of the situation.

I therefore submit my definition of endoaneurismorrhaphy and the operations that are derived from it.

SYNONYMS AND DEFINITIONS.

Endoaneurismorrhaphy.—The "Matas operation" (Bullock); "the radical operation for the cure of aneurism by the intrasaccular suture of the aneurismal orifices," essentially consists of two fundamental procedures: (1) the obliteration, by suture, of the vascular orifices which open into the aneurismal sac; (2) the obliteration of the sac by suture which brings its inner surfaces in apposition, or by methods of obliteration which leave the sac undisturbed and tend to secure primary healing by plastic union. In obliterating the vascular orifices that supply the sac, the parent trunk which nourishes the aneurism may be preserved or obliterated at the point of attachment according to the type of sac encountered. Hence the subdivision of endoaneurismorrhaphy into three varieties:

1.—*Obliterative endoaneurismorrhaphy* (the fundamental procedure), essentially consists in opening the sac freely without disturbing it from its surroundings and closing all visible arterial orifices within the sac, by suture, thus securing complete hemostasis and permanently stopping all further access of blood into the aneurismal cavity. The sac is obliterated by approximating its walls with buried sutures, and closing the wound with or without drainage; or, in rigid cavities, by simply infolding the overlying skin flaps and lining the cavity with them (*capitonnage* of the French) or by one of the several procedures or variations I have suggested.

The indications for the application of this obliterative suture, or fundamental procedure, are: All aneurisms in which the sac is of the fusiform type, in which there are two or more orifices of supply and in which the parent artery is entirely lost at the seat of the aneurism by blending with the aneurismal sac throughout its circumference. In these cases no attempt is made to restore the continuity of the parent artery; the blood stream is interrupted in that part of the vessel which directly opens into the sac and the arterial orifices are simply closed by suture, thus shutting off the sac from all sources of blood supply.

Up to the present time twenty-two cases illustrating this mode of procedure (obliterative endoaneurismorrhaphy) are exhibited in the group of thirty-four aneurisms contributed by American operators. Possibly several of the foreign cases are of this type, but as the contribution of Dr. Lozano has not yet appeared, we are not yet in a position to state the type of cases included in his report.

2.—*Restorative endoaneurismorrhaphy.* This variation in the procedure is solely applicable to aneurisms of the sacciform type, in which the parent trunk retains its continuity and normal outline, and the aneurism is a sac simply grafted on the vessel. By opening the sac freely and washing out the clot, the opening leading to the artery is exposed inside of the aneurism and is readily closed by a continued suture which penetrates through all the coats of the sac at the margin of the orifice of communication. By this procedure the blood supply of the sac is permanently arrested, the lumen of the parent artery remains patulous and the arterial stream supplying the limb, or dependent territory, is immediately restored through its normal channel. The sac is then obliterated by bringing its endothelial surfaces together with buried sutures and the surface wound is closed in the usual manner. Up to the present time seven operations of this type have been reported by American surgeons, all successful, and two, at least, of the foreign cases may be appropriately added to this list, making nine in all.

3.—*Reconstructive endoaneurismorrhaphy* (arterioplasty) is applicable solely to fusiform aneurisms in which the coats of the sac are firm, elastic and resistant and the two openings leading to the main artery lie on the same level, in close proximity, and are situated at the bottom of a superficial or readily accessible sac.

In aneurisms of this type, especially those of traumatic origin, the continuity of the parent artery may be restored by making a new channel out of the sac walls which can be brought together by suture over a guide (catheter or drainage tube) inserted into the proximal and distal openings of the aneurism. Before tying the last sutures, the guide is removed and the channel is left behind corresponding to the outline of the original artery. The sac is then obliterated by approximating its surfaces with buried catgut suture, as previously applied in the first and second procedures. Thus far, five cases of this operation have been reported, all by American surgeons. Two of these patients have relapsed. The first, Morris' case, was followed in six months by an amputation of the thigh, though it is recognized that a secondary operation by the obliterative method would have obviated the necessity for this sacrifice. In the second case (Danna's) when relapse occurred the sac was reopened, the obliterative method was applied with permanent and perfect success. The surgeons in the other cases (Craig Barrow of Savannah, 2; Van Lennep of Philadelphia, 1) report that their patients continue to do well, and, thus far, without relapse.[8]

SUMMARY.

Total, 34 cases of aneurisms of different types, reported by 21 American operators:

I. GEOGRAPHICAL DISTRIBUTION.

NEW ORLEANS: R. Matas, 5; J. A. Danna, 4; H. B. Gessner, 1; F. W. Parham, 1; F. W. Parham and E. D. Martin, 1; S. W. Stafford, 2; W. Kohlman and J. Newman, 1; total, 15.

NEW YORK: Robert Morris, 1; Willy Meyer, 1; Robert I. Abbe, 2; F. H. Markoe, 1; total, 5.

LEXINGTON, KY: W. O. Bullock, Jr., 4.

SAVANNAH, GA.: Craig Barrow, 2; George H. White, 2; total, 4.

PHILADELPHIA: J. H. Gibbon, 1; Chas. H. Frazier, 1; W. B. Van Lennep, 1; total, 3.

KANSAS CITY, MO.: J. F. Binnie, 1.

INDIANAPOLIS: H. O. Pantzer, 1.

PUGET SOUND, WASH.: D. N. Carpenter, U.S.N., 1.

FOREIGN (classed as atypical): Le Fort (Lille), 1 (popliteal);[9] G. del Conte (Naples), 1 femoral (sacciform); R. Lozano, Saragossa, 4 (abdominal aorta, 1; subclavian, 1; popliteal, 2).

II. ANATOMIC DISTRIBUTION.

POPLITEAL, 19 (55 per cent.): Matas, 2; Bullock, 2; Robert Morris, 1; J. H. Binnie, 1; Craig Barrow, 1; H. O. Pantzer, 1; H. B. Gessner, 1; J. H. Gibbon, 1; J. A. Danna, 2; Willy Meyer, 1; F. W. Parham, 1; Robert Abbe, 1; F. H. Markoe, 1; S. E. Stafford, 1; Charles H. Frazier, 1; W. E. Van Lennep, 1.

FEMORAL, 11: Matas, 1; Bullock, 2; Danna, 2; G. R., White, 2; D. N. Carpenter, 1; Stafford, 1; Kohlman and Newman, 1; Craig Barrow, 1.

GLUTEAL: Robert Abbe, 1.

BRACHIAL: Matas, 2.

SUBCLAVIAN: Martin and Parham, 1.

III. SEX.

American Cases: Males, 32; Females, 2. Foreign: Female, 1 (del Conte); male, 1 (Le Fort).

Ages in 34 American cases: Youngest, 12 years; oldest, 65 years; majority between 30 and 60 years.

IV. ETIOLOGIC CLASSIFICATION.

TRAUMATIC, 8: Matas, 2; Pantzer, 1; G. H. White, 2; W. Meyer, 1; Markoe, 1; Bullock's fourth case, 1.

TRAUMATO-PATHOLOGIC, 14: Matas, 2; Bullock, 2; Gibbon, 1; Danna, 3; Parham, 1; Abbe, 2; Carpenter, 1; Martin and Parham, 1; Van Lennep, 1.

Cases classed in this group give a distinct history of some indirect traumatism (strain, lifting, indirect falls, etc.) associated with a pathologic arterial basis (syphilitic, alcoholic, arteriosclerotic).

---

[8] Craig Barrow's first case was operated on May 28, 1904; his second case, April, 1906; Van Lennep's, Jan. 17, 1906.

[9] The popliteal was extirpated after development of another aneurism in a different part of the artery.

Pathologic, 12: Matas, 1; Morris, 1; Binnie, 1; Barrow, 2; Gessner, 1; Bullock, 1; Danna, 1; Stafford, 2; Kohlman and Newman, 1; Frazier (?).

In accordance with accepted teaching, it is more than probable that the cases grouped as "pathologic" should be classed as "traumatopathologic," as there is always some direct or indirect traumatism which determines the localization of aneurisms in conditions of general arterial disease. The distinction of "pathologic" is made in the absence of a clear, recognized, local determining cause. This distinction is useful probably in accentuating the preponderance of the pathologic over the traumatic element in the causation.

V. TYPE OF ANEURISMAL SAC.

Fusiform, 23: Matas, 4; Bullock, 4; Morris, 1; Barrow, 2; Gessner, 1; Danna, 4; Gibbon, 1; Parham, 1; Parham and Martin, 1; Carpenter, 1; Stafford, 2; Van Lennep, 1 (nearly 64 per cent.).

Sacciform, 11: Matas, 1; Binnie, 1; Pantzer, 1; White, 2; W. Meyer, 1; Abbe, 2; Markoe, 1; Frazier, 1; Kohlman and Newman, 1. Foreign, 2; (2 sacciform Le Fort and del Conte).

VI. PROCEDURE ADOPTED.

1. Obliterative Endoaneurismorrhaphy: (Applied to fusiform aneurisms) 22 out of 34 American cases: Matas, 5; Bullock, 4; Binnie, 1; Gessner, 1; Danna, 3; Gibbon, 1; Parham, 1; Abbe, 2; Stafford, 2; Martin and Parham, 1; Carpenter, 1.
2. Restorative Endoaneurismorrhaphy: (All sacciform aneurisms) 7 cases: Lumen of parent vessel restored. Pantzer, 1; White, 2; Meyer, 1; Markoe, 1; Frazier, 1; Kohlman and Newman, 1.
3. Reconstructive Endoaneurismorrhaphy (Arterioplasty), applied to fusiform aneurisms, 5 cases: R. Morris, 1; Craig Barrow, 2; J. A. Danna, 1; Van Lennep, 1.

VII. TREATMENT OF SAC.

A—Typical obliteration of the sac without drainage, according to the author's first method. Total, 10 cases: Matas, 3; Bullock, 4; Craig Barrow, 2; G. H. White, 1.

B—Atypical obliteration of the sac, without infolding skin flaps, (buried sac method): Morris, 1. Binnie, 1; Pantzer, 1; Gibbon, 1; Meyer, 1; Parham, 1; Abbe, 2; Markoe, 1; Stafford, 1; R. H. White, 1; Kohlman-Newman, 1; Frazier, 1.

C—Atypical partial obliteration of the sac by approximating walls and surrounding parts, packing and draining: Matas, 2; Danna, 4; Gessner, 1; Carpenter, 1; Stafford, 1; Martin and Parham, 1; Van Lennep, 1.

VIII. POSTOPERATIVE RESULTS.

(a) Deaths: None directly attributable to the operation. (1) One patient (Pantzer's) died fifteen days after operation from associated pyelitis and nephritic coma while the healing of the wound was progressing satisfactorily. (2) Another patient (Stafford's No. 2), a negro, aged 59, died seventy days after the obliteration of a femoral aneurism by suture. This patient was the victim of the aneurismal diathesis. The first aneurism developed in the right popliteal and was extirpated after it had ruptured, Oct. 6, 1905. While the patient was slowly recovering from an infective synovitis of the knee following the operation, he developed a second aneurism in the upper left femoral, which grew rapidly and was obliterated by intrasaccular suture on March 30, 1906. Twenty days after the last operation, and while the wound was healing satisfactorily, the artery above the obliterated aneurism dilated and ruptured at a point where a traction loop had been applied, during the operation, for hemostatic purposes. The dilatation of the artery and rupture coincided with a violent acute edema of both lungs, caused, perhaps, by pulmonary thrombus or infarct. Great cyanosis, temperature 104 F., and intense dyspnea characterized this attack, which subsided after thirty-six hours, leaving the patient in great prostration. At this juncture the artery ruptured and a profuse hemorrhage with enormous hematoma occurred. The femoral was ligated above the seat of rupture a little below Poupart's ligament. Infection and suppuration occurred, followed by gangrene of foot. Six days after this ligation (April 26) secondary hemorrhage occurred at the seat of the ligature, necessitating the ligation of the external iliac above Poupart's ligament. The gangrene of the limb was marked. May 25, 1906, amputation at middle of thigh. Bed sores developed and the patient sank exhausted and marasmic, June 6, 1906.

While these events were taking place it was noticed that the right common femoral and abdominal aorta were undergoing dilatation, which would have developed into aneurisms had the patient survived. It is to be noticed that the circulation of the limb was perfect after the obliteration of the left femoral aneurism by endoaneurismorrhaphy, and that gangrene of the foot and leg did not occur until a ligature was applied to the artery above the obliterated sac.

(b) *Secondary Hemorrhage: None,* except as it occurred (in Stafford's No. 2) from causes not directly attributable to the method.

(c) *Gangrene: None,* except in Case 2 (Stafford), where it followed the application of a secondary ligature, as above described.

IX. RELAPSES.

(a) In obliterating endoaneurismorrhaphy (22 cases), none; (b) in restorative endoaneurismorrhaphy (7 cases) none; (c) in reconstructive endoaneurismorrhaphy or arterioplasty, two relapses out of five cases.

Of the two relapses amputation was performed in one case (Morris) by demand of the patient. In Danna's case (No. 2) the aneurism was cured by obliterative suture, after the relapse (following arterioplasty), became apparent. The other three patients (Craig Barrow, 2; Van Lennep, 1) have continued to do well up to date.

Arteriovenous aneurisms treated by separate suture of artery and vein, or by distinct applications of the suture technic, as distinguished from the ligature, were reported by Zoege v. Manteufel (1895), Camaggio (1898); Gerard-Marchant (1898), Peugniez of Amiens (1900), Korte (1904), Oliver of Uruguay (1904), Danna of New Orleans (1905), and Gessner of New Orleans (May, 1906).

2255 St. Charles Avenue.

DISCUSSION.

Dr. Willy Meyer, New York, reported the case of a young boy, 11 years of age, who, in cutting a stick in the woods, cut his popliteal artery by a slip of his knife. The wound was small but bled much. The boy was carried to the hotel where he was staying in a very weak condition. An improvised Esmarch bandage, a handkerchief and a stick, was applied and the nearest doctor sent for, who stitched the wound. After 12 days the boy was brought to New York, with a somewhat stiff knee. The family physician advised active and passive exercises. Four weeks later the boy noticed a throbbing tumor in the popliteal space. When Dr. Meyer first saw the patient, three months later, December, 1904, the tumor had all the characteristics of a popliteal aneurism, and having heard Dr. Matas' paper read at Albany, and being familiar with his experience with his operation, he concluded to try that method. An Esmarch bandage was applied. He cut down on the sac and found a sacculated aneurism. The sac was a large one with the opening low down, so that it was some time before he discovered just where the opening was situated. On account of this deep situation Dr. Meyer thought it best to introduce a large flexed copper sound into the lower portion of the artery, and it was pressed down by the assistant into the base of the sac so as to permit of making the suture as low as possible. After he had succeeded in running the suture across the opening, the probe was extracted and he continued the suture. After Dr. Meyer had placed the first continuous suture (silk) the crucial point came, viz., the removal of the Esmarch bandage. He was delighted to see that after its removal there was only a slight parenchymatous oozing. He closed the sac with a number of continuous sutures of chromicized catgut, and had the pleasure of seeing the whole wound heal nicely within 10 days. To-day the boy is cured entirely and uses his leg as well as he did before the operation.

Dr. R. C. McChord, Lebanon, Ky., reported a case of popliteal aneurism operated on according to the method described by Dr. Matas. The case was one of gunshot wound of the artery inflicted two years before I saw the patient. The aneurism was situated high up in the popliteal space, and at the site of the wound it was about the size of a hen's egg. It had recently burst. He constricted the leg above, cut down through the sac and stitched up the opening. But before he stitched up the sac, being a little fearful about his technic, and before closing the sac, Dr. McChord loosened the constrictor. There was a little hemorrhage. He simply took a bite down with the ligature and then proceeded to close the sac as Dr. Matas suggested. The wound healed by first intention, except one small spot where there was some infection, possibly due to faulty technic. The patient returned to his home within two weeks after the operation. The man had been home only a few days when there was a slight secondary hemorrhage. The doctors became alarmed and placed constriction above the point of bleeding for a few hours, and when the constriction was removed there was no further hemorrhage and the man made an uneventful recovery.

Dr. Stanley Stillman, San Francisco, said that he had employed this operation in one case. He emphasized the importance of thorough application of the Esmarch bandage, particularly because it is exceedingly difficult to reapply it when that is necessary. In his case, also one of popliteal aneurism, the patient stated that he had only noticed the tumor, which was about the size of a small egg, for three weeks. The sac could not be obliterated because of two reasons. There was not really a properly organized sac and the openings into the aneurism could not be closed by sutures that would hold. He advised this operation strongly, but cautioned those who attempt it to wait, in cases of recent aneurism, till the sac has become sufficiently tough to hold the sutures, and has become properly lined with endothelium.

DR. GEORGE R. WHITE, Savannah, Ga., has had two cases of aneurism on which he operated according to Dr. Matas' method. Both were aneurisms of the femoral artery, and both were of traumatic origin; one was caused by a stab wound and the other by a bullet wound. In both instances the operation was carried out successfully, and the patients are now at work and are as well as they ever were. He emphasized the point Dr. Matas made that the operation is not a difficult one if his description is followed closely.

DR. RUDOLPH MATAS said that he deeply appreciated the kind words of encouragement and praise expressed by the various speakers. He said that he realized most convincingly, however, that the good that there is in the method he suggested, especially its simplicity and safety, could never have been demonstrated without the coöperation of the 20 American surgeons who, with their characteristic alertness and keenness to test new ideas—as well as by their ability—have so quickly furnished the remarkable evidence which he submitted.

THE VALUE OF X-RAYS IN OCULAR THERAPEUTICS.

G. ORAM RING, A.M., M.D.
Ophthalmic Surgeon to the Episcopal Hospital, Philadelphia; Ophthalmologist to the Widener Memorial Home for Crippled Children, Philadelphia; Consulting Ophthalmologist to the American Oncologic Hospital, Philadelphia.
PHILADELPHIA.

Amid the illuminating advances that have characterized the rapid progress of medical science during a trifle more than the last decade, the spectacular and beneficent discovery of Professor Roentgen, of Wurzburg, occupies a position of acknowledged preëminence.

The classical papers which first startled the world of science have been followed by a flood of literature emanating from hosts of enthusiastic workers from almost every corner of the globe, and while the hopes and promises have to some extent failed of materialization yet the amazing therapeutic results that have been wrought up to the present moment should abundantly merit our profound appreciation and study.

Ophthalmic science has had its quota of fleet-footed workers, eager to develop the far-reaching possibilities of the newly discovered form of radiant energy. It is our purpose to institute an inquiry into the results thus far achieved and to attempt to define the present position of the *x*-ray therapeutics as applied to several important branches of ophthalmology.

When we consider the *x*-ray from a therapeutic standpoint we are, according to Freund,[1] dealing with the following forces emanating from the surface or within a vacuum tube in action: (1) heat, (2) ozone, (3) cathode rays, (4) ultra-violet rays, (5) rays composed of material particles, (6) Roentgen rays, (7) spark and brush discharges from the high tension, electric accumulation on the surface of the tube, (8) electric and electro dynamic waves, (9) waves of unknown character. Stern[2] believes the only rays that need to be considered are the *x*-rays, the unknown rays and the electric discharges from the surface of the tube.

The histological sequelæ of the *x*-ray application (Stern) are stimulation of the vaso-constrictor nerves of the blood vessels, paralysis of these nerve filaments accompanied by vascular dilatation, edema, the result of paralysis carried to a higher degree, and finally complete nerve paralysis, accompanied by destruction of tissue.

It is impossible in so brief a communication to place before you a complete summary of the brilliant work which the electro-therapeutist has achieved, but many opinions of value have been gleaned from the copious, and at times, polemic literature of the last few years. In answer to a communication addressed to many of the foremost ophthalmologists and *x*-ray experts of our country, I am able to present to you a number of hitherto *unpublished opinions* regarding the results of the application of this form of therapy to disease of the eyes and ocular adnexa. In the discussion to follow I hope that the various and at times divergent views expressed may be crystallized into definite and unfailing methods of technic that may make the amazing results claimed by certain observers a usual sequel of the application of this form of energy.

In a malignant disease of the eyelids and adjacent structures, radiotherapy (because of the favorable character of the resulting cicatricial tissue) finds one of the most satisfactory fields. When Steinbeck,[3] of Stockholm, exhibited before the Swedish Medical Society, a case of epithelioma, which he had cured by means of Roentgen therapy, a stimulus was given to this important work, which, *notwithstanding its triumphs, must* still be conceded to be in its incipiency.

My experience in a considerable group of epitheliomas, involving the eyelids and contiguous skin structures, and varying in size from a base of 10 mm. in its longer diameter to an extensive ulceration, at times embracing half of the upper and lower lids, and extending well on to the bridge of the nose, several of which were totally inoperable, has been so uniformly satisfying that I am accustomed to leave little doubt in may patient's mind regarding the certainty of a cure. In only one such case that has come under my observation was there any tendency to a recurrence at the end of about eighteen months. This was subjected to a few further treatments and has remained in perfect condition through the succeeding year.

Mayou[4] and D. Walsh (London) presented a most promising series of results before the Roentgen Society, Dec. 2, 1902, the former claiming that all cases of so-called rodent ulcer of the eyelids can be cured. The inflammation which can be produced by the *x*-ray varies, according to these authors, from a mild leucocytosis *(stimulation) to an absolute destruction of tissue.* Added experience seems to emphasize the opinion, early expressed, that this profound change is largely superficial, and is not produced by the rays that penetrate deeply. It is the function of the leucocytes to break up and remove all irritating substances, or to encapsulate and thus render them innocuous.

One of our foremost authorities, William Allen Pusey[5] (Chicago), reports having treated several cases of epithelioma, in which there was no involvement of the deeper orbital tissues, and all resulted in cure where sufficient treatment was permitted. No relapses have occurred, and some of the cases were treated about three years ago. John Green, Jr.,[6] St. Louis, Mo., also concludes that in epithelioma and rodent ulcer of the eyelids, *x*-ray therapy surpasses all other methods of treatment and can be relied on to cure all such cases.

Sweet[7] believes that it is no longer right to resort to plastic operations in these two conditions, basing his judgment on the successful results of 18 out of 20 cases treated.

John E. Weeks[6] (New York) regards the *x*-ray treatment of very great value in epithelioma and has placed at my disposal the notes of one private case of epibulbar epithelioma of very great interest.

The patient, a man aged 54, had a growth occupying the inner half of the ocular conjunctiva to the caruncle, and involved about the inner third of the cornea.

Diagnosis was confirmed by microscopic examination.

About 100 *x*-ray exposures were given, extending over a period from March, 1905 to January, 1906; the exposures averaging 7 minutes each at 10 inches from the Gundelach anticathode using a tube of medium tension. Patient is virtually well. Vision 20/40. Tissues of the globe have not suffered. The exposures were made through a tube 1¼ in. in diameter. There was no other protection.

De Schweinitz[6] (Philadelphia) has had four cases of "entire and rapid cicatrization" with no relapse. In two additional cases the results were entirely negative, or possibly the condition was aggravated. In one of the latter, excision was practiced with subsequent application of the rays, without recurrence. De Schweinitz concludes the rays should be tried for a certain period, and if the results are not good, then excision with or without plastic operation should be practiced.

Charles Lester Leonard[6] (Philadelphia) whose experience has been extensive in treatment of epitheliomas and various skin lesions involving the eyelids, regards it as uniformly and permanently successful. Baker[6] (Cleveland) writes that he has had five cases of rodent ulcer with perfect recovery. One case of special interest has been under observation for ten years, but all this time the disease was slowly progressive, not only the eye, but the cheek and temple were involved. The eye was enucleated and, later, *x*-ray applications were made for a year or more less regularly, resulting in complete cicatrization with no evidence of recurrence at the end of four years. In a sixth severe case in which both *x*-ray and radium were used, a complete cure has been effected, the curative agent being, in Baker's judgment, the Roentgen ray. In eight cases of epithelioma, the results have been entirely satisfactory, although in most of the cases the knife was used and followed by the *x*-ray. There have been no recurrences. Baker had two cases of lupus involving the eyelids that have been "very greatly improved if not entirely cured by the *x*-ray."

Hermann Knapp[6] (New York) has seen "four temporary results in epithelioma and the like." Stevenson[6] (Albert Lea, Minn.) has used the *x*-ray with success in treatment of lupus of the eyelids only. Newcomet[6] (Philadelphia) advises me that he has treated about 30 cases, few of which have shown any disposition to recur.

The names of a host of foreign and home workers in ophthalmologic or electrotherapy lines could be added, if additional testimony were needed, among them Hamer,[8] Hall,[9] Darier[10] and Bettremieux;[11] in our own country, Taylor,[6] Dixon[6] and Marple[6] (New York), St. John[6] (Hartford), Holt[6] (Portland), Black[6] (Milwaukee), Wescott[6] (Chicago), Howe[6] (Buffalo), Schamberg,[6] Hansell,[6] H. K. Pancoast,[6] S. Lewis Ziegler[6] (Philadelphia). Schamberg's case is of considerable interest, as the case involved not only the lids, but the conjunctiva as well., A perfect cure was effected without sign of recurrence at the end of two years.

S. C. Ayres[6] (Cincinnati) has had one case of epithelioma of outer and lower margin of right cornea of six years' duration. It was curetted, but soon recurred. Under *x*-ray treatment, pain was relieved and the condition improved. He was not kept under continuous treatment, and later increase in the growth compelled enucleation.

Bulson[6] (Fort Wayne) advises me that in four cases of extensive carcinoma two were cured, a third probably cured, and the fourth did not continue treatment. Woods[6] (Baltimore) believed the rays successful in preventing a recurrence after an orbital evisceration for extensive carcinomata.

Würdemann[6] reports a case of carcinoma of the orbit beginning in the skin of the external canthus. The operation consisted of exenteration of orbit and resection with partial removal of malar, superior maxillary and orbital process of the frontal bones. The patient was treated about two years by *x*-rays several times a week; a suspicious sore was removed by secondary operation, and the result was complete cure with full lining of orbit by skin.

X-RAYS IN SEVERE CASES.

As illustrative of the curative possibilities of the rays in the more extensive carcinomatous involvement of the orbital and adjacent tissues, it is only necessary to refer to cases of which this one reported by Dr. Pusey,[5] of Chicago, is a type:

Deep Carcinoma in the Orbit.—Patient of Dr. Wm. H. Wilder, treated by Dr. Pusey.

The growth involved all of the structures in and around the orbit, and the terrific intracranial pain seemed to leave little doubt of meningeal involvement.

After nearly two months of treatment and a resulting *x*-ray burn coincident with increasing pain, the case was regarded as hopeless and discharged. About six months later it was found he was still living; the mass had shrunk and lids would close. He is free from pain, eats and sleeps well.

Of the 10 cases so carefully reported by Chas. S. Bull,[12] two were extensive carcinomata. One was a case of the eyeball and orbit in which operation was advised, but declined. The case was cured by twenty-seven *x*-ray exposures. The other was a case of deep-seated carcinoma involving the nose, eyelids and orbit, likewise perfectly cured by thirty-four exposures.

As noted by George C. Harlan[6] (Philadelphia), J. W. Pancoast[6] and many others, with whom probably all of us are in accord, it must be remembered that in many of the deep-seated growths of the carcinomatous type the rays have totally failed to arrest the disease, but even in such cases there is little doubt of the pronounced anodyn effect of the exposures, and, while, as suggested by Nelson Black[6] (Milwaukee) and others, the deeper the orbital involvement the less favorable result can be expected, yet the estimate of Jackson[6]

(Denver) that it is of great value even in the more extensive types of orbital carcinoma can be abundantly maintained.

SARCOMA.

In a previous paper[13] I considered the use of Roentgen therapy in attacking this form of malignant neoplasm. Reference was made to the remarkable result in L. Webster Fox's case of inoperable sarcoma involving the orbit and accessory sinuses apparently cured by fifty exposures to *x*-ray. A daily treatment of five minutes' duration, with a high vacuum tube placed at 10 in. distance, containing a current of 4 amperes, was maintained for 4 weeks, the frequency of the treatment then being reduced on account of an excessive erythema.

In the same paper the gratifying reports of a number of cases of sarcoma *x*-rayed by Leonard and by Pfahler, of Philadelphia, involving the face, neck, lip, nostril and antrum were accepted as giving promise of similar brilliant results with improved technic, when the growth involved the orbit and surrounding structures. The immediate application of the method was suggested before radical operation was attempted. If unsuccessful in removal of the growth, Leonard, who has had a very wide experience, claims that its virulence will be decreased and the dangers of metastasis lessened. Other methods of attack were carefully considered in the event of failure with the *x*-ray.

I will refer now to a few additional reports of cases treated by the rays as introductory to a further discussion of this important subject.

Beclere[14] reports the case of a patient affected with sarcoma of the floor of the orbit who was cured by *x*-rays. The disease had lasted four years. Two operations had been performed, the last one including removal of the eye. All other methods of treatment had failed, but improvement set in as soon as radiotherapy was employed. Histologically, the tumor was found to be a malignant sarcoma. Beclere reports an additional case of orbital sarcoma cured by *x*-rays.

Kienbock[6] reports a sarcoma cured by *x*-rays. This case is of very unusual interest. A growth having appeared in the nose seven years before, in spite of operations oft repeated, had invaded the adjoining structures and produced exophthalmos on both sides with subsequent optic atrophy. Pain ceased after the first treatment, and after thirteen applications the growth (an endothelial sarcoma) entirely disappeared. Eyes resumed their normal appearance and vision partly returned. Grossman[6] reports a similar case which had almost entirely disappeared under the *x*-rays.

Theobold[6] (Baltimore) has had one case of marked exophthalmos (unpublished) with the diagnosis of inoperable sarcoma of the orbit—a diagnosis in which two other surgeons concurred. Under the *x*-ray treatment the case rapidly improved and after a lapse of seven months seemed to be cured. Pfahler[6] advises me that he has treated three cases of primary orbital sarcoma, with resulting disappearance of the growths. A fourth case, which was recurrent, showed no ultimate improvement.

When to these reports we add the case of Mosely,[15] orbital sarcoma, that of Pratt,[15] melanosarcoma of orbit, that of Harper,[16] melanosarcomatous pigment areas on the sclera, and that of Fox,[17] true sarcoma of the lids, all cured by radiotherapy, we surely have abundant reason for some satisfaction at the results already achieved.

Many observers have utilized the rays successfully in preventing a recurrence after the removal of malignant orbital growths, notably sarcoma, and the recent experience of Wescott[6] (Chicago) and Chas. S. Bull[12] and Marple[6] (New York) will serve to bring to our attention this important phase of the subject. Wescott advises me that he exenterated a case of orbital sarcoma, and, feeling positive that all of the disease was not removed, subjected the patient to *x*-ray treatment for three months. There was no evidence of recurrence at the end of one year. On the other hand, Bull, in his painstaking report of eight cases of orbital sarcoma, has not found radiotherapy of value as a curative agent either before or after operation. He, however, believes it distinctly effective in the relief of pain. Marple has had one case of orbital sarcoma with exenteration of the orbit. *X*-ray was used in the effort to prevent a recurrence, which it failed to do. In one of my own cases it seemed to prevent a recurrence *in loco*.

TRACHOMA.

In the treatment of the nodular formations or masses of round-cell infiltration of the conjunctiva, known as trachoma, the ophthalmologist has found one of his most difficult problems. The various remedies used may be classed under the heads of chemical or mechanical irritants. The excessive and often damaging cicatricial tissue remaining after the application of the chemical irritant classes this method as far from ideal.

The rolling, brushing and other allied methods are of unquestioned value, but the cures are frequently incomplete even with the added chemical treatment. The cure is wrought, in part, by mechanically removing the diseased masses and, in part, by the induction of a leucocytosis with subsequent cicatrization. Since the disease is probably allied to lupus, it may be caused by an undiscovered bacillus, the destruction of which by the methods noted results in pronounced betterment.

Stephen Mayou[18, 4] lauds most highly the results achieved by *x*-ray treatment of this condition, claiming (1) less deformity of the lid after treatment, (2) it is practically painless, (3) the pannus clears more thoroughly. His first case, presented before the London Ophthalmological Society early in 1902, was apparently the initial application of the method. "Instead of the white puckered conjunctiva gained by other methods, a supple non-contracted, non-scarred conjunctiva, with no obliteration of the fornices," was noted. In every one of 15 cases a perfect result was achieved. No burning of the globe occurred in any case. Two-minute exposures were given from four to six successive days, followed by a week's rest; then came semi-weekly exposures until slight photophobia began. When granules disappear, the treatment should cease, as the infiltration induced by *x*-ray will be some weeks in subsiding. The patient is seated 9 inches from the anode with a moderately soft tube and a current of 6 amperes. The metal mask formerly used is now discarded, as the patient is not exposed sufficiently to get any skin reaction.

[18] Mayou: "The Treatment of Trachoma by X-Rays," Trans. of the Ophth. Soc., London, S. 10.

Stevenson and Walsh[19] selected severe cases which ordinarily required a very prolonged treatment by old methods, and they were cured in a few weeks. They report equally good results in a case treated less than two months with a high frequency current. After twenty-three painless applications of the brush discharge from a vulcanite electrode connected with a Cox's d' Arsonval apparatus, a disease disappeared that would have lingered on two or three years under ordinary treatment.

Walsh[20] (London) has treated four cases of severe double trachoma, with complete cure in two and marked improvement in the remaining two. Good effects were the same if lids were closed or everted.

Vassutinsky[21] obtained favorable effects on trachoma by means of the Roentgen rays. These rays diminished the infiltration, caused the disappearance of the granulations and of the pannus, and produced a pronounced improvement in the subjective signs of the malady. As a rule, however, trachomatous granulations disappeared but slowly under the influence of Roentgen therapy. The rays proved to be harmless in treating the eyes, no evil effects were noted in any case, nor was pain experienced by the patients. The author thinks that the rays are of service in cases in which ordinary methods of treatment fail.

Ruggero Pardo[22] reports two cases of trachoma which derived benefit from the application of *x*-rays.

CASE 1.—The patient, aged 60, had suffered from double trachoma for three years. In the right eye was dense pannus, abundant catarrh, and congested iris. The left eye was similarly affected, but to a much less degree.

CASE 2.—The patient, aged 14, had had trachoma two years. A Crookes tube with a spark about 700 mm. was used at a distance of 45 to 30 cm. for four to ten minutes at a time. Only one eye was treated, the other being carefully protected with a metallic shield. About six applications were made in each case at intervals of three days. As a result of the treatment the conjunctiva became smoother, the secretion ceased, the pannus cleared, and there was marked improvement in vision in the first case. In the second case many of the tarsal follicles disappeared, the secretion diminished, and there was considerable improvement in the subjective sensations.

Geyser[23] maintains that a few exposures, six to eight, will suffice to bring about a perfect cure. An important consideration is to cause absorption and stimulate normal nutritional processes; nothing seems to answer the purpose any better than the direct contact of the tissues with a high-frequency vacuum tube generated by a static machine or *x*-ray coil. Complete details of technic are given in the article.

Horniker and Romanin[24] (Trieste) report the history of three successful cases of trachoma treated by *x*-rays. The methods of Mayou, Cassidy, Rayne and Pardo are compared. The method of Mayou of applying the rays directly to the everted lids was selected, as the strength of current did not have to be judged with such exactness in order to prevent skin lesions. Cassidy and Rayne applied the current to the closed lids. Notwithstanding the care exercised, dermatitis of the hands developed and, for the purpose of holding open the everted lids, Romanin devised an instrument which is carefully described and which is said to make the performance perfectly comfortable to physician and patient. He claims that one single advantage of the Pardo method which makes prominent the retrotarsal fold can likewise be obtained by his instrument by placing a compress behind the everted lid and by turning the lid holder by screws. Although eminently successful in three cases, Horniker does not attempt to decide on its final value until a larger mass of authoritative material shall have been collected.

The investigation of Heineke[25] as to the results of the application of the *x*-rays in disease of the spleen and other lymph organs in rabbits, more particularly in leukemic conditions, pointed to a destruction of lymphocytes in the follicles.

Buschke and Schmidt[26] found a cessation of proliferation of cells in kidneys and testicles, which confirmed the earlier findings of Albers Schonberg[27] concerning azoospermia. These results induced Stargardt[28] (Kiel) to investigate the results of the rays on trachoma mass, which is essentially composed of lymph follicles.

Kuhnt (Königsberg) has practiced excision of the upper retrotarsal folds for many years. It was at his clinic that Stargardt was permitted to *x*-ray the folds before excision. In the application the method of Kienbach was modified; that is to say, one long exposure (twelve minutes with soft tube distance of 5 cm.). Stargardt believes there is no danger to the conjunctiva in these exposures. Microscopically the principal change was noted in the follicles. In one instance the retrotarsal fold was excised in 16 hours; in a second, 30 hours; in a third, in 14 days. In the first and second cases highly colored masses were scattered over the whole follicle which were regarded as the remains of destroyed nuclei. These masses varied in shape and size from that of a lymphocyte to that of the smallest particle. They were mostly strongly colored with the stain, a few less intensely so, though very scarce some were non-stained. These masses lie mainly between the cells, partly in the phagocytes. The phagocytes are similar to the Villard type. Their number is increased. They are unevenly distributed over the whole follicle and do not show the regular arrangement usually seen in trachoma. In addition to the increase of phagocytes, a strong increase in Villard's giant cells was also noted. The giant cells are very plentiful, and we also find from three to six large black colored nuclei which lie in a mass of plasma substance. The decrease of threads produced by the segmentation of cells was very striking.

Cassidy and Rayne[29] (Baltimore) report the case of an artist's helper who suffered for nine years from granular lids.

Patient had been operated on twice with grattage and twice by avulsion. The usual astringent and caustic treatment was also exhausted. Treatment was begun November 8, 1902, through closed lids. Cautious tentative exposures of three minutes each, separated first at intervals of ten days, then five days, then tri-weekly exposures were given at a distance of 12 inches, and a spark gap of one-sixteenth of an inch. These treatments caused excessive lacrimation which diminished on successive exposures and finally ceased. By the thirty-fifth exposure both eyes were free from trachomatous granules. The patient's lids are now little inflamed and are not thickened. The mucous membranes are still red, but free from swelling and discharge. There are absolutely no trachomatous granules, photophobia is entirely absent, and the patient uses her eyes constantly without discomfort.

The effect, according to three writers, is neurotrophic. Normal tissues are stimulated to a new vigor, and pathologic tissue, always being of less resistance, assumes a retrograde metamorphosis.

At a regular meeting of the Philadelphia County Medical Society, Nov. 23, 1904, W. S. Newcomet and J. P. Krall[30] (Philadelphia) exhibited a girl of eighteen who had been subjected to all the operations for the cure of trachoma without success.

Patient was treated with the *x*-ray from July, 1903, until January 1, 1904. The inflammatory reaction was so intense that it was thought better to abandon the treatment. Later, however, it was found that she could count fingers at close range. The cornea of the eye was entirely clear and only with special illumination could fine blood vessels be seen. The eye not treated with the *x*-ray showed all the symptoms that the treated eye formerly exhibited. The condition of the patient had been present since infancy, and she had been unable to see across the room. Treatment was given every other day for five minutes for about six weeks, when a burn developed and treatment was withheld. Newcomet believed the result to be due to the accidental burn produced in the course of treatment.

H. N. Bishop[31] (London) gives the results of electrical treatment of trachoma at the Middlesex Hospital. Cases had been treated with well equipped apparatus, with rays, high-frequency currents, and radium. With regard to the *x*-rays he explains that there were two sets of rays emanating from the tube, (1) the *x*-rays proper, (2) the overflow rays that cause the severe burning of the skin which sometimes occurred. The former of these rays were used. Four cases of trachoma were treated in this manner. Two were young women. In one, fifty applications were made in five months. The right eye showed changes that might reasonably have been produced in this time without treatment, while the left, which was at first unaffected, steadily got bad. The disease subsequently cleared up in the usual manner with bluestone. None of the three other cases did any better. The seven cases treated with high-frequency currents did not improve at all.

Kassabian[6] (Philadelphia) has treated four cases in his work at the Philadelphia Hospital, two acute and two chronic. All of the photophobia and lacrimation markedly manifest in the acute cases disappeared after four or five exposures and the results achieved in all four cases were so satisfactory that Kassabian believes we have in the *x*-ray a most valuable curative agent, if properly used. Kassabian's technic in treating cases of trachoma consists in covering the Crookes' tube with a dark cloth and darkening the room. He uses adhesive plaster to fix the lids and expose the surface of the eye, to prevent the burning of the nurse's or assistant's fingers. He covers the face with a leaden sheet and treats one eye at a time through an aperture in the lead. Rapidity of action is obtained by getting the patient to keep the eye open while under treatment. There is less danger of burning the cornea than there is to the skin of the eyelid, but should a slight corneal haziness result it quickly disappears and a corneal scar will be absorbed.

W. Franklin Coleman[6] (Chicago) says that in 12 cases of trachoma his results in the treatment have been so uniformly favorable that he would not consider any other method. Coleman's first case was exposed to the *x*-ray July 1, 1903. The disease was of 20 years' standing. A high-frequency tube was used with ten minutes' exposure three times weekly. A perfect recovery resulted in six weeks. He now uses a two and a half inch spark, ten minutes' exposure at six inches with low tube, with lids closed and no mask. Every case treated has resulted in perfect cure.

Ayres[6] (Cincinnati) reports one severe case of trachoma with marked hypertrophy of conjunctiva. Three other cases, trachoma, less severe, all resulted in perfect cure. Pfahler[6] (Philadelphia) has treated 15 cases of trachoma with *x*-ray. All showed improvement, a few decided improvement. He believes the rays should be used after accepted methods have been given a fair trial. He has never seen any harm result to the eye from the exposures.

Schamberg[6] (Philadelphia) has treated one case at the Polyclinic Hospital with most satisfactory results. There were pronounced vegetations on the tarsal conjunctiva. Pain was relieved and the vegetations disappeared. In this case the eyelids were averted and the rays applied directly to the granulation. Twenty-five treatments of five minutes' duration were given twice weekly.

Jackson[6] (Denver) advises me that in his experience *x*-ray does some good and may cure acute cases, but not more quickly or certainly than older methods. It has not cured or permanently benefited the bad cases. L. Webster Fox[6] (Philadelphia) has utilized *x*-ray, but not with encouraging results. Fox prefers the older recognized remedies. Suker[6] (Chicago) states that the *x*-ray has given him no results or even encouragment in treating trachoma of any type. de Schweinitz[6] (Philadelphia) regards the results as fairly good in the few cases in which he has used the method, but considers his experience too limited to render an expression of his opinion of value. Ordinary therapeutic agents or operative measures have served him as well. With improved technic and exact dosage, the measure offers a prospect of success and should be given the fullest trial. His personal experience is limited to two cases, neither of which was as much benefited as it would have been under ordinary treatment in the same period. He has seen two cases in the care of colleagues in which the results were somewhat better than those that follow the usual applications and surgical procedures. Sweet[6] (Philadelphia) has treated a number of cases of trachoma by the *x*-rays, but did not consider the results to be any better than could be secured by the usual local measures.

VERNAL CONJUNCTIVITIS.

The utterly unsatisfactory results of all forms of treatment of this extremely intractable type of conjunctival hypertrophy determined Allport[32] (Chicago) to test the *x*-ray in a case of characteristic palpebral type.

The patient, a young lady, aged 19, living in a refined and wealthy environment, gave a history of seven years' experience with the disease. The growths were first amputated, then subjected to about eighty *x*-ray applications in less than three months. Photophobia, redness, itching and irritability were removed at once, and the patient apparently perfectly cured, since she has gone through two subsequent summers without any recurrence of the disease.

---

[30] Newcomet and Krall: Trans. Philadelphia County Med. Soc., Nov. 23, 1904.

[31] Bishop, Harman N.: "Electrical Treatment of Trachoma," British Med. Jour., Aug. 26, 1905.

[32] Allport: "A Case of Vernal Conjunctivitis," Ophthalmic Record, October, 1903.

The case was *x*-rayed by Pusey, and the diagnosis confirmed by Casey Wood, Woodruff and Guilford, Chicago.

Pusey[6] has had one additional case in which the disease was cured. William Campbell Posey[6] (Philadelphia) believes that *x*-ray exerted decided influence on the course of the disease. He has kindly placed at my disposal a brief note of his case.

The patient, a man, aged 35, came to the Wills Eye Hospital in May, 1905, with the statement that for two years preceding, during the warm months, his eyes had annoyed him greatly with itching and smarting, increased lacrimation and great sensitiveness to light. These symptoms had subsided with the appearance of cold weather again in the autumn. On examination, it was noted that the patient was suffering from a typical attack of vernal conjunctivitis of the palpebral type, the conjunctiva being greatly infiltrated and whitened, and there being a number of flattened granulations in the conjunctiva of the upper lid. The bulbar conjunctiva was unaffected.

Antiseptic washes of boracic acid and cocain, and solutions of adrenalin, in strengths varying from 1-10,000 to 1-5,000, were prescribed. The patient was instructed also to report to the Polyclinic Hospital for the administration of the *x*-rays. These were continued during the summer months, the applications being made twice a week, and each seance lasting about five minutes. Subjective symptoms were apparently greatly influenced by the rays, for notwithstanding that local treatment was interrupted for a time, the itching and smarting sensations were much less in severity. After some weeks treatment the follicles underwent a change and became markedly less pronounced. While during the preceding August and September the patient had suffered great annoyance, these months were passed in great comfort. No deleterious action from the rays, either on the eye or adnexa, was manifested at any time.

Zentmeyer[6] (Philadelphia) has had two cases of vernal conjunctivitis treated by means of *x*-ray by Sweet, one resulting in perfect cure, the second in marked improvement.

In the first of Zentmeyer's cases, a boy of 15, the affection was in both eyes, but worse in the right. The upper lids were studded with typical flat granulations. At the limbus above and to the temporal side were the nodular swellings overlapping the cornea. When treatment was stopped, a year ago, the granulations had entirely disappeared from the lids, but a few of the nodules persisted at the limbus. He passed through last summer without any discomfort and at the present time the palpebral surfaces of the lids are normal. The few nodular swellings still remain, but have not increased during the year. The boy was so satisfied with his improvement that he did not return for further treatment.

Sweet[6] had two remaining cases, which disappeared from treatment after the subsidence of acute symptoms. de Schweinitz[6] (Philadelphia) has utilized *x*-ray in only one case of vernal conjunctivitis. The treatment was of short duration, and the negative result ought not to be utilized in any estimate of the value of this agent in treating this form of conjunctival diseases. Suker[6] (Chicago) has had sufficient experience to convince him that *x*-ray treatment of vernal conjunctivitis is of positive value. Jackson[6] (Denver) believes that *x*-ray sometimes diminished the discomfort, but prolonged trial has shown no curative influence.

CONGENITAL NEVI.

At this writing I am having treated a case of nevus of the left upper eyelid, which had attained considerable proportions. There is apparently being effected a rapid cure.

Stewart (Thomas S.) and Given (Ellis V. W., Philadelphia) advise me they have likewise had several apparent successes with the rays.

CHRONIC CONJUNCTIVITIS.

By courtesy of Kassabian[6] (Philadelphia) I am enabled to add to the various types of cases amenable to *x*-ray treatment that of chronic conjunctivitis.

The patient, a man, aged 35, had suffered for seven years, with an obstinate type of this condition. Every important method of treatment had been exhausted by the two distinguished surgeons, Knapp of New York and Jackson of Denver, whose patient he had been. At the suggestion of Dr. Schneideman of Philadelphia, and with the added recommendation of Knapp and Jackson, *x*-ray treatment was begun in June, 1904. During all treatments the eyes were open, there were no signs of dermatitis, the lashes and brows were not the least affected by treatment. Patient is perfectly well. He insists on exposing both eyes to the rays once a month for five minutes, which Kassabian regards as unnecessary, considering the cure complete.

In the language of Kassabian, the technic is as follows:

Induction coil (15-inch spark producing) energized with 110-volt current, mechanical interrupter 2 amperes going to primary coil. Crookes' tube with "medium vacuum" anode being at a distance of 12 to 15 inches (30 to 38 cm.). The face and chest were covered with a sheet of lead through one opening of which the patient looked towards the tube during exposure. Treatments were given for the first three consecutive months twice a week, the time of exposure being gradually increased from one to two minutes. On September 19, 1904, after twenty-four exposures, the condition was greatly improved; the conjunctiva had become pale on the eye that was treated. During October, November and December treatment was continued only once a week, exposure two and one-half minutes. Treatment was discontinued for two months (January and February, 1905) and begun again March 1, with an exposure of three minutes once a week. Blood vessels are very small and fine, conjunctiva pale and white. Regular treatment was continued three months longer.

GLIOMA.

Hilgartner[33] gives a brief note of a most extraordinary result of Roentgen ray treatment in a case of double glioma in a child aged three and one-half years. The growth in the right eye largely filled the vitreous and could easily be seen in its incipiency in the left eye. Pain was severe. Eighty-four exposures were given. Right eye shrank to two-thirds of its natural size and the growth in left eye was entirely absorbed.

Pusey's[33] results have been sufficiently encouraging to warrant his urging the use of the rays after removal of glioma and sarcoma to prevent a recurrence.

Würdemann[6] reports one case of glioma beginning in retina and extending to orbit, maxillary antrum and nasal passages. Three exenterations of the orbit were performed. *X*-rays were finally used for one year with a result of hindrance of development and absolute prevention of pain.

GUMMATA.

Parker, F. C.[6] (Norristown) reports a most interesting case of bilateral gumma of the orbit in a child eight years of age. Diagnosis was confirmed by microscopic examination, specific and *x*-ray treatment were both instituted, and it was Parker's opinion, based on the course of the case and its final cure, that the Roentgen ray applications were of very positive value.

---

[33] Quoted by Pusey and Caldwell: "Therapeutics of Roentgen Ray," 609.

SCLERITIS AND EPISCLERITIS.

Pardo[22] in his long and interesting communication believes the results of *x*-ray in scleritis and episcleritis represent a real discovery inasmuch as at present there is no other direct therapeutic agent but only means amounting to a purely symptomatic treatment.

CORNEAL ULCERS.

Dennett[34] reports having observed that ulcers of the cornea are stimulated to rapid healing by the rays. Williams[34] reports a case of flat leucoma in the lower half of cornea. Exposures were given once a week for three months, then twice a week for two months, after which the scar was smaller, smoother, and less dense and vision improved.

UVEITIS.

Jackson[6] (Denver) is utilizing the rays in traumatic uveitis. Several times they have given immediate relief from pain and seemed to bring about rapid improvement. In other forms of uveitis he has not seen any marked effect from it.

TUBERCULOSIS OF CONJUNCTIVA.

Sidney Stevenson[35] reports the following case:

A poorly nourished, pallid child, aged 4, was placed under treatment November, 1902. Trachoma-like material was found in semilunar fold. Lid was half closed and thickened lower palpebral conjunctiva was strewn with miliary granulations and folds of coxcomb like tissue. Similar changes were in the superior retrotarsal fold. Tubercular bacilli were found locally. There were positive results from inoculation experiment. Thirteen *x*-ray exposures of ten minutes resulted in complete cure of the conjunctival disease. Enlarged submaxillary glands were present and were removed by operation.

CAUTION IN USE OF THE RAYS.

It is important that a note of warning should be sounded regarding the possibility of unlooked for results of a serious character which are said by competent observers occasionally to follow *x*-ray exposures. They would seem to indicate the very great importance of referring our cases to none but experts in Roentgen therapy. I have seen several cases of temporary corneal haze, conjunctivitis and marked episcleral congestion, but all such conditions subsided with the cessation in the use of the rays.

Dr. Henry K. Pancoast, chief of the *x*-ray department of the University of Pennsylvania, warns us regarding the possibility of the induction of severe conjunctivitis, ulceration and opacity of the cornea, edema of the conjunctiva and lids and optic neuritis. If the growth overlies the eyeball a hard rubber, ivory or metal eye spatula may be inserted under the lids.

In one of Sweet's cases of rodent ulcer the application of the rays was followed by the dulling of the mental faculties the following day. Wild reports a case of epithelioma in which the *x*-ray treatment was followed by the development of panophthalmitis, necessitating the removal of the globe. This must be regarded as a result so exceptional as to be unique.

Birch-Hirschfeld believes the rays capable of leading to very serious results if not skillfully applied. In his experiments on rabbits he believes he has certain proof of the existence of blepharitis with loss of hair and eyelashes, conjunctivitis keratitis profunda, and iritis. Some cases showed evidence of optic atrophy. The microscope in certain instances revealed degeneration of the ganglionic layer of the retina. In four clinical cases, marginal keratitis with vascularity was noted. These serious changes would seem to be the outcome of too lengthy exposures to the action of the rays. Indeed, Pusey of Chicago in one of his excellent early papers remarks on the possibility of producing atrophy of such highly differentiated epithelial structures as the retinal rods and cones, and regards the production of an inflammation of the conjunctiva as quite as likely as that of the skin structure. Hallopeau and Godaud[34] found the patient experienced a disagreeable impression of bright light after long exposure.

Subcutaneous extravasations of blood are said to have resulted in several instances, and Ehrmann quoted by Charles S. Bull described a telangiectatic appearance as a late result of *x*-ray exposure. A few cases of sarcoma and carcinoma by Burdick, Butler, Culey, Edwards and Pusey have been reported in which exacerbations of pain occurred as the result of the exposures.

CONCLUSIONS.

1. *X*-ray therapy marks a great advance in the treatment of superficial epithelioma and rodent ulcer of the eyelids and can usually be relied on to effect a cure.
2. If unsuccessful then electro-chemical sterilization may be utilized, or finally excision with or without plastic operation.
3. *X*-ray treatment has proven of value in the more extensive orbital carcinomata, but it is conceded that the deeper the growth the less favorable will be the result.
4. A sufficient number of cures of sarcoma of lids and orbit have been reported to warrant its exhaustive trial in all types of this disease. More radical operative procedures with subsequent ray applications being indicated in event of primary failure.
5. *X*-ray treatments usually exert an anodyn influence on malignant disease of the eyelids and orbit, but are occasionally reported to cause exacerbations of pain.
6. Noteworthy progress in the treatment of trachoma has been effected by the utilization of *x*-ray therapy. It should invariably be utilized if ordinary methods fail.
7. The weight of evidence indicates the positive value of *x*-ray treatment of vernal conjunctivitis.
8. There is evidence which points to the value of *x*-ray therapy in chronic conjunctivitis (Kassabian), scleritis, episcleritis (Pardo), traumatic uveitis (Jackson), conjunctival tuberculosis (Stevenson), corneal ulceration (Dennett), glioma (Hilgartner and Würdemann) and gummata (Parker).
9. It is believed that the rays will cure malignant disease involving the cornea and conjunctiva, provided treatment is applied sufficiently early.
10. The treatment of congenital nevi by the rays is likely to prove effective and should be exhausted before electrolysis or radical operation is considered.
11. Further testimony must be accumulated before an authoritative statement is possible of the effect of *x*-rays in painful types of iridocyclitis and glaucoma and other ocular diseases.

DISCUSSION.

Dr. George S. Dixon, New York, said that we have been for some time, and are still, passing through the experimental stage of Roentgen therapeutics, and that the earlier and many of the later, ideas of the greatest number of workers in this line must be toned down considerably. So much is heard about the success, but nothing at all of the failures, as few men care to acknowledge defeat, and for this reason the time for judging the exact value of any therapeutic measure is delayed.

---

[34] Quoted by Allen: "Radiotherapy in Ophthalmology."

[35] Stevenson: "Tuberculosis of Conjunctiva," Boston Med. Jour., 1903, p. 1313.

Dr. A. R. Baker, Cleveland, states that he has had a number of cases of epithelioma in which he thinks the *x*-ray has brought about recovery. He has seen several cases of sarcomatous tumors involving the sinuses in which there has apparently been no benefit, except in the relief of pain, except in one case of adenosarcoma involving the septum of the nose. He reported the case six years ago as recovered, but it recurred and an extensive operation was done, removing the growth and as much tissue as possible; in a few months there was recurrence involving the ethmoid and sphenoid sinuses. In consultation with some of the best surgeons it was decided that the case was an inoperable one, and it was turned over to an *x*-ray specialist and to the surprise of every one the patient recovered. That is five years ago and the patient is apparently enjoying good health now.

Dr. John Green, Jr., St. Louis, said that he has recently had under observation a case which illustrates the partial failure of the *x*-ray. A woman, aged 65, was operated on about hirteen years ago for mammary cancer. Six years ago she eloped a cutaneous ulcer over the right ala nasi, which inased in size and resisted caustic applications. Finally a eries of *x*-ray exposures succeeded in controlling the disease at that site. About two years ago, the disease began at the inner third of the right upper lid. Dr. Green saw her first eighteen months ago at which time there was complete immobility of the lid, with destruction of a portion of the margin. He referred her to a competent *x*-ray therapeutist who instituted treatment. In the course of the thirty seances the tumor become so much smaller that the patient could voluntarily raise the lid. In the meantime, however, a nodule appeared at the upper inner angle of the orbit which increased in size despite continuous applications of the ray. Operation was advised but refused.

Dr. Casey A. Wood, Chicago, added his testimony to that of Dr. Jackson's as to the value of the rays in the treatment of malignant tumors that are essentially fatal. He particularly referred to two he has had of secondary gliosarcoma following glioma of the retina. He had the usual experience in enucleating a number of eyes for this disease, but in one case he did an extensive evisceration and had the *x*-rays used afterward. In spite of the rays, however, the secondary tumor occurred as usual and came up to the margin of the orbit, but he was not called on for two years to do another operation, and he thinks that is of great importance. The value of the *x*-ray should not be forgotten in relieving pain and preventing the horrible edema. It helps along until the time when the meninges become affected and the patient dies from secondary invasion of the brain. If it does not cure it is at least of value as an agent of relief.

Dr. C. D. Wescott, Chicago, referred to the case of sarcoma of the orbit mentioned by Dr. Ring in which the ray was used three months and the patient was living at the end of a year. He stated that the patient is still living at the end of three years. Dr. Wescott saw the patient about a year after enucleation of the eye for sarcoma. There was a good-sized tumor which he removed by subperiosteal exenteration. The actual cautery was used on the tissues which could not be removed with scissors and curette and then the patient was subjected to the *x*-rays for three months.

Dr. W. B. Marple, New York, stated that he had one case of recurring sarcoma in which an exenteration of the orbit was done and subsequently the *x*-ray was applied to the orbital tissues. The result was entirely negative and the growth promptly recurred.

Dr. William Sweet, Philadelphia, said that he has had a number of cases of carcinoma, granular lids and vernal conjunctivitis, some of which recurred because the patients failed to return for treatment after the superficial ulcerated area had healed. Although the skin surface was completely healed, there remained a hardened mass at the site of the growth, showing that while the disease had been relieved temporarily, there were still some of the cancer cells deeply situated. In the treatment of sarcoma in the deep orbital structures Dr. Sweet said that we must not forget that active treatment without sufficient drainage is dangerous to the patient. The *x*-rays have a destructive action, and in extensive disease proper drainage must be provided, otherwise the system will be unable to elimate the broken-down tissue. Dr. Sweet has treated a number of cases of trachoma, but has failed to secure results sufficiently satisfactory to warrant the use of the rays in this disease. He has had three or four cases of vernal conjunctivitis, all of which were benefited by this treatment. One boy had typical granulations on the under surface of the lids and around the cornea. The surface of the lids became perfectly normal under the treatment and the granulations at the limbus decreased in size and number although they have not entirely disappeared.

Dr. L. Webster Fox said that since the *x*-ray plant has been established at the Medico-Chirurgical Hospital it is being used in all cases of superficial and deep growths in and about the eyelids and orbit. The first important case that was placed under such treatment was the one quoted by Dr. Ring. Since then there have been three similar cases with like results. The first evidence of benefit in these cases was the diminution in the size of the swelling and relief from pain. The first patient suffered so much that she was unconscious at times, and tetany was very pronounced. It was only with large doses of opium that rest and quiet could be obtained. After four or five applications of the *x*-ray the relief from pain and swelling was marked, and continued so throughout the treatment, until all swelling and pain disappeared. In that case, however, the patient has since had metastatic sarcoma of the liver, which caused her death. As regards the inoperable cases of sarcoma of the orbit, he said the *x*-ray should always be given a thorough trial. In the superficial cancers (the epitheliomata) the usual good results, ending in a cure have been obtained. Quite recently a case came under Dr. Fox's observation, in which two-thirds of the upper lid was destroyed. He scraped the tissues thoroughly and applied the *x*-ray for several weeks, by which time all evidence of induration had disappeared. Over this denuded surface he transplanted a flap of skin, which united perfectly. At the Medico-Chirurgical Hospital 100 cases of various inflammations of the lids from the dispensary were placed at the disposal of the *x*-ray therapeutist—the results were not satisfactory. Other means, such as grattage, sometimes bring about better results. Dr. Fox's method is to evert the lids and with a piece of ordinary gauze scrub the surface, and he thinks that the results are just as good, if not better, in the soft gelatinous papules as by any other method. He has at present an interesting case of leukosarcoma of the iris in which eight applications have been made and it looks as if the disease were slowly disappearing. If a cure can be brought about in this case it will be remarkable. Here one can observe the action of the *x*-ray directly through the transparent cornea on the growth which is now about the size and shape of a grain of wheat.

Dr. C. L. Leonard, Philadelphia, said that he is glad to note that the ophthalmologist appreciates the use of the *x*-ray and believes that it should be used by the *x*-ray therapeutist. If surgeons would appreciate that more and the medical men too they would secure better results. In the deeper growths one is able to secure perfect results. These results are coming, but they will only come with further development of technic, which we do not possess at the present time. We can hardly expect, he said, to reach the deep-seated growths that have already produced metastases. One *x*-ray specialist said that he does not consider a patient cured of malignant disease until he has died of something else and autopsy shows that the malignant disease is not there. Patients often remain apparently well for three or four years and then have recurrences. This method produces results not by removing diseased and normal tissue but by restoring the normal though altered metabolism. The cosmetic result is much better. One can not replace the hair follicles if they have been destroyed. Dr. Leonard has a patient now in whom the upper lid was more than half involved and the hair follicles were destroyed; the patient is well, but the hair can not be restored; otherwise the eyelid is like the other. Dr. Leonard agreed with Dr. Ring and Dr. Sweet that we must get rid of the broken-down tissues produced by the rays. The production of toxemia is proof of efficient treatment, but is also an indication for the cessation of treatment. The *x*-ray therapeutist learns that he must get near the production of that toxemia, but he must have drainage for the byproducts caused by the destructive process. When this is done he is approaching as closely as possible to the destruction of malignant disease and restoration to normal. We are destroying the disease *in situ*. The work is not yet perfected and we must get better results, he said, before we speak of cures. In these deep-seated growths the relief afforded by the *x*-ray treatment is a blessing to humanity. Relief from pain in these cases is constant. The patient is free from suffering without the use of narcotics which destroy the sense of perception.

Dr. D. L. Edsall, Philadelphia, declared that he is so much impressed with the importance of recognizing the great potency for harm, as well as for good, in the *x*-ray, that he should desire to emphasize the point again. A year ago in reporting the first observations that he made on the effect of the *x*-ray on metabolism, he said that it is undoubtedly the most violent known agent used for therapeutic purposes, and that this demonstrates both great possibilities for good and great potentiality for harm. Since ophthalmologists do not purposely use the *x*-ray for its general effect on metabolism, the possibilities for harm are to them of more especial importance in this regard. As indicating such harmful possibilities, he would say that he has been so unfortunate as to see, in one of his own cases and in two cases of colleagues, violent general systemic reactions to a single application of the *x*-ray. Two of these cases soon ended fatally, largely as the result of the *x*-ray exposure; while the third patient became almost moribund, but finally recovered. The last case, he emphasized especially, for it was one of chronic rheumatoid arthritis in which the direct exposure was merely to one arm from the elbow downward and it was only five minutes in duration. There was no direct exposure of the trunk, although there was a distant diffuse exposure of the whole body, as the parts not purposely exposed were not protected from exposure. This shows clearly that a very mild exposure may have an exceedingly dangerous result. He emphasized also the fact that this patient was already somewhat ill from a chronic cystitis and that the clinician in charge of him, who is a very careful man, did not recognize that the severe illness following the exposure was due to the action of the *x*-ray. Dr. Edsall, however, feels confident that it was due to this, because in a previous observation he had noted exactly the same conditions of metabolism as those which appeared in this case, in a case in which there was certainly a general violent reaction to the *x*-ray. This demonstrates also, he said, what many persons have already come to admit: namely, that occasionally dangerous reactions occur as the result of exposure to the *x*-ray, and that their relation to the *x*-ray has in many instances been entirely overlooked. It is not at all surprising, he said, that violent toxic reactions may occur as the result of *x*-ray exposures. The observations that he has made show that one exposure, even, may double the metabolic output in the next few hours; and, clearly, the necessity for metabolizing and excreting such an amount of destroyed tissue must be dangerous in a good many instances. He said that he did not desire to arouse general opposition to the use of the *x*-ray. It has been too clearly shown that it is occasionally a therapeutic agent of great temporary, and perhaps of permanent, value, and is of unquestionable diagnostic importance. He would insist, however, on the importance of employing it for therapeutic or diagnostic purposes with less recklessness than has characterized its use by many of the profession hitherto. In cases such as ophthalmologists meet it is, as a rule, sufficient to protect all parts except those that are purposely exposed; but he considers that it is extremely important to do this, in order to avoid occasional dangerous general reactions, and even if toxic reaction does not occur, we should avoid giving an unnecessary general dose of an agent that always does more than merely take a picture or influence superficial lesions. In the cases that fall into the hands of the medical clinician, the matter is even more important. In such instances, Dr. Edsall believes that it is of great importance that the patient's general condition should be thoroughly known before referring him to the *x*-ray specialist; and a careful conclusion should be reached as to whether he is a proper subject to expose at all to the *x*-ray.

Dr. G. O. Ring, Philadelphia, said with reference to Dr. Dixon's remarks on the treatment of superficial epitheliomata that his own results were somewhat at variance, inasmuch as in all of his cases there had been complete and comparatively rapid cicatrization. He had no experience with the crushing of the nodules previous to the application of the *x*-ray. He felt that Dr. Coleman's experience in the treatment of trachoma was entitled to full consideration, as the technic had probably been faultless. He would unquestionably use the rays in any intractable case. He entirely agreed with Dr. Bull as to the present limitation of the ray treatment in deep seated carcinomata and sarcomata. He has had only two cases of sarcoma, one in which there was no recurrence in loco, and another which is now under treatment; the patient is doing well, the tumor being reduced about three-fourths. Dr. Ring has had only one case of sarcoma of the iris in which there was a question of diagnosis as to one of those rare forms of congenital syphilis, tuberculosis or sarcoma. It was treated with antisyphilitic remedies and with tuberculin without result. *X*-ray treatment was begun and carried on daily, and in three weeks the growths in the iris, which had been increasing, promptly began to disappear. Two of the original nodules could be watched through the clear cornea and have now practically gone, and the third is beginning to lessen. In confirmation of Dr. Weeks' observation on retinal tolerance to the *x*-ray, he had not seen any case in which the retina showed any untoward result. Dr. Ring expressed the hope that the brilliant result in Dr. Baker's clearly inoperable case involving the accessory sinuses might with perfect technic and exact dosage be the usual sequel to the application of Roentgen therapy. Dr. Ring said that it was his purpose in the opening of the discussion to have made reference to Dr. Zentmayer's case of vernal conjunctivitis. He gave the doctor credit with using the words "perfect cure" when he preferred the word "inhibited."

THE ECONOMIC ADVISABILITY OF INAUGURATING A NATIONAL DEPARTMENT OF HEALTH.*

J. PEASE NORTON, Ph.D.
Assistant Professor in Political Economy, Yale University.
NEW HAVEN, CONN.

This is an age of progress, intellectual, social and, above all, material—of progress so colossal that the eternal forces of Nature are gradually abandoning the long fight and one by one surrendering to the mind and hand of man. But with all that has been wrought there yet remain broad gaps in our organization which, if left unheeded, may blight the civilization itself. In the present paper an attempt is made to point out what may be regarded as the most serious hiatus in our social system and to consider a possible remedy based on more efficient organization. Societies, like skillful capitalists, should strive to invest their revenues so as to yield maximum returns. When returns are direct and may be charged for, experience has shown that the management in many cases may be judiciously entrusted to private individuals. When social investments produce conditions rather than commodities, indirect services impossible to measure as they occur unit by unit, but which nevertheless result in large substantial gains measurable in the aggregate, the management must be entrusted to national agencies, sufficient in magnitude to produce the results desired.

In an age of great things, a civilization must not be staggered by its own creations. Greater and greater things must it do because of the necessity that compels it. To falter is to lose grip, and to lose grip means a more or less slow destruction of the civilization by divers melancholy wastes.

---

*Read before the American Association for the Advancement of Science, Ithaca, N. Y., June 30, 1906.

The salvation of the civilization and of the race lies in the hands of exceptional men. The hope of the race rests in its efficient organization for action. Efficient organization consists in compelling each individual to do that thing within his capability which has greatest value for society. To do otherwise is a great waste. To permit great wastes to go unchecked is more than a suicidal policy; for an evil more destructive than race suicide is race homicide.

There are four great wastes to-day, the more lamentable, because they are unnecessary. They are preventable death, preventable sickness, preventable conditions of low physical and mental efficiency and preventable ignorance. The magnitude of these wastes is testified to by experts competent to judge. They fall like the shades of night over the whole human race, blotting out its fairest years of happiness.

The facts are cold and bare—1,500,000 persons must die in the United States during the next twelve months; equivalent to 4,200,000 persons will be constantly sick; over 5,000,000 homes, consisting of 25,000,000 persons, will be made more or less wretched by mortality and morbidity.

We look with horror on the black plague of the middle ages. The black waste was but a passing cloud compared with the white waste visitation. Of the people living to-day over eight millions will die of tuberculosis, and the federal government does not raise a hand to help them.

The Department of Agriculture spends seven million dollars on plant health and animal health every year, but, with the exception of the splendid work done by Doctors Wiley, Atwater and Benedict, Congress does not directly appropriate one cent for promoting the physical well-being of babies. Thousands have been expended in stamping out cholera among swine, but not one dollar was ever voted for eradicating pneumonia among human beings. Hundreds of thousands are consumed in saving the lives of elm trees from the attacks of beetles; in warning farmers against blights affecting potato plants; in importing Sicilian bugs to fertilize fig blossoms in California; in ostracizing various species of weeds from the ranks of the useful plants, and in exterminating parasitic growths that prey on fruit trees. In fact, the Department of Agriculture has expended during the last ten years over forty-six millions of dollars. But not a wheel of the official machinery at Washington was ever set in motion for the alleviation or cure of diseases of the heart or kidneys, which will carry off over six millions of our entire population. Eight millions will perish of pneumonia, and the entire event is accepted by the American people with a resignation equal to that of the Hindoo, who, in the midst of indescribable filth, calmly awaits the day of the cholera.

During the next census period more than six million infants under 2 years of age will end their little spans of life while mothers sit by and watch in utter helplessness. And yet this number could probably be decreased by as much as one-half. But nothing is done.

In the United States alone, of the eighty millions living to-day, all must die, after having lived, say, a little more than 3,200,000,000 years of life, on the average slightly more than two score years. Of these years, 1,600,000,000 represents the unproductive years of childhood and training.

Consider that the burden of the unproductive years on the productive years is 20; 20, or say 100 per cent. Could the average length of life be increased to sixty years, say to 48,000,000,000 years lived by 80,000,000 of people, the burden of the unproductive years would fall to 50 per cent. In the judgment of men competent to hold opinions, this is not impossible.

The states' rights doctrine can be applied against the Department of Agriculture as effectively as against a national department for health. It is not, then, a question of constitutionality, but, rather, of whether or not such a department is needed by the nation.

The idea is by no means a new one. As far back as 1879 Dr. Benjamin Ward Richardson advocated by articles and books the establishment in Great Britain of a ministry of health. Solvay, in Belgium, has emphasized the importance of this field for government action. Sir Francis Galton, in recommending the study of the new science of eugenics, created by his own investigations, holds that the laws now being worked out by the brilliant group of mathematical biologists in England bearing on such subjects as heredity or homotyposis, reproductive selection, inheritance of longevity and mental traits, and disease causation, should become the basis of constructive action by the state. And this point of view has been the subject of much discussion at the meetings of the British Sociological Society.

Two years ago, an interdepartmental committee was appointed by the British parliament under these terms of reference: (1) "To determine the steps that should be taken to furnish the government and the nation at large with periodical data for an accurate comparative estimate of the health and physique of the people; (2) to indicate generally the causes of such physical deterioration as do exist in certain classes, and (3) to point out the means by which it can be most effectually diminished."

The committee returned a report recommending a permanent advisory council, in substance a national department of health, along with fifty-two other constructive measures.

In America, physicians connected with the American Medical Association for a number of years have advocated that the executive cabinet include a secretary of health. The necessity for such a department has also arisen in connection with the Panama Canal. Indirectly, two medical experts are now associated with the canal organization. In 1906, Mr. Hubert Higgins, in a book entitled "Humaniculture," elaborated the advantages and necessity for national action through a thoroughly equipped national department of health. The recent book by Dr. Shadwell, a physician, on "Industrial Efficiency" tends to the same conclusions.

Certain divisions of the work of such a department are now performed by other executive departments, and these bureaus would form excellent nuclei for the organization. The names of those bureaus now engaged to some extent along lines not foreign to the purpose of such a department and their appropriations follow:

Public Health and Marine-Hospital Service (Treasury Department)	$1,290,000
Bureau of Animal Industry for the Inspection of Meat (Department of Agriculture)	1,525,000
Life-Saving Service (Treasury Department)	1,841,000
Total	$3,656,000

The logic that justifies an annual appropriation of $2,000,000 for a life-saving service against the accidents of the sea should justify protection against accidents of disease and death. Other bureaus more closely connected with health regulation than at first sight appears are:

Bureau of Labor (Department Commerce and Labor)	$ 176,000
Bureau of the Census, vital statistics (Department Commerce and Labor)	1,400,000
Bureau of Immigration (Department Commerce and Labor)	2,126,000
Total	$3,713,000

Agitation for the factory acts, the eight-hour day, regulations concerning female and child labor and immigration is justified primarily as health regulation.

The total is, in round figures, seven millions out of a total national expenditure of about $725,000,000. These bureaus should be included in the work of the health department. Many other services, however, should be added, the beginnings of some of which appear in recent bills either passed or now before Congress.

Among these bills is the Meat Inspection Bill, which provides rigid inspection of meat and meat products and regulates the sanitation of slaughter and packing houses. These regulative powers are entrusted in the bill to the Department of Agriculture, which is unfortunately already overburdened with a too diverse series of problems. Moreover, this department is necessarily more concerned with encouraging and protecting the producers in the various industries than in guaranteeing the health of the consumer. Commercially, the interests of the producers and consumers are often at variance. This service should be administered by a national department of health.

The National Quarantine Law recently passed forms the basis for a bureau of national quarantine.

The Pure Food Law provides for the rigid inspection of food and food products, as well as drinkables and medicines. Severe penalties are imposed for adulteration and false labelling. This bill extends federal powers into affairs with which the states have dealt very generally with laxity. The grave danger in state regulation lies in the strong tendency to use these laws indirectly as a protective measure against the products of other states.

There must arise many differences of opinion with respect to the practicable division of powers in the organization of a national department of health. An organization is suggested in the following paragraphs, not for the sake of occasioning argument over details which would necessarily be the subject of careful investigation, but in order to present positive prolegomena for discussion:

1. It seems desirable that a United States National Department of Health should be established, having as its head a secretary, who shall be a member of the executive cabinet.

2. The purpose of the department should be to take all measures calculated, in the judgment of experts, to decrease deaths, to decrease sickness, and to increase physical and mental efficiency of citizens.

3. It is probable that a national department of health could be advantageously made to consist of the following bureaus:

National Bureau of Infant Hygiene.
National Bureau of Education and Schools.
National Bureau of Sanitation.
National Bureau of Pure Food.
National Bureau of Registration of Physicians and Surgeons.
National Bureau of Registration of Drugs, Druggists and Drug Manufacturers.
National Bureau of Registration of Institutions of Public and Private Relief, Correction, Detention and Residence.
National Bureau of Organic Diseases.
National Bureau of Quarantine.
National Bureau of Health Information.
National Bureau of Immigration.
National Bureau of Labor Conditions.
National Bureau of Research, requiring statistics.
National Bureau of Research, requiring laboratories and equipment.

4. At the present time of vast undertakings, the magnitude of this department should not be lightly passed over. Great ends must be wrought out through adequate organization. To make headway against death, morbidity, cancer, tuberculosis, we must use dynamite and in large charges.

To equip human machinery, consisting of exceptional men, organized and kept in action for this task, with suitable apparatus and adequate supplies, at least one hundred millions of dollars should be annually appropriated by the nation.

5. The health department should receive its support:

(a) From licenses levied on persons and industries inspected, stamp taxes and registration fees.

(b) From national appropriations.

6. The scope of the work of the fourteen bureaus is briefly discussed in the following paragraphs. The organization is framed from the standpoints of (1) economy of operation, (2) effectiveness of administration, (3) adequacy of results. It is, of course, out of the question to attempt to give specific reasons for each bureau in the space allotted:

A. Bureau of Infant Hygiene.—This bureau should investigate and regulate conditions causing infant mortality. Registration of births and marriages would enable wholesale education of parents by means of pamphlets and leaflets concerning the care of the child, food, air, dress, etc., such as the model pamphlets of the Illinois Bureau of Health. Continuation classes and education of older girls in schools, as well as regulation of female employment during and after pregnancy, are recommended by the British committee; also medical certificates as to the cause of death and registration of still births. The establishment of municipal milk stations now going on in European cities should be adopted. The famous Randall's Island experiment, where sterilized milk feeding reduced infant mortality from 41.83 per cent. in 1895-7 to 16.52 per cent. in 1904, is pertinent. McCleary estimates for eleven European cities a decline from an average of 20.2 per cent. to 18.3 per cent. by partial use of municipal milk depots. The work of Dr. Goler, of Rochester, is still more striking. The damage wrought by impure milk, soothing syrups and parental ignorance is probably equivalent to a decrease of several years in average age at death of the entire population.

B. Bureau of Education, Schools and Children's Homes.—This bureau could coöperate with the local schools in (1) medical inspection of children and anthropometric measurements, (2) extension of the New York system of disease examination by permanent nurses, (3) municipal treatment of defective eyes, ears, teeth and segregation of defective children, (4) inspection of buildings used and methods of schools, children's homes, etc., from sanitary and educational standpoints, (5) systematic education of children in right living along practical lines.

C. National Bureau of Labor Conditions.—This bureau should investigate and frame legislation for proper conditions under which labor may be employed. The excellent work already being done by the present Bureau of Labor should be expanded. The length of the working day, hours of rest, etc., should have more attention, and proper regulations should be enforced.

D. Bureau of Sanitation.—The subject of sanitation and ventilation should be very thoroughly investigated, with a view to establishing standards (1) for sewerage systems of cities and towns; (2) water supply; (3) air purity, by regulating smoke and chemical pollution; (4) proportion of building and open spaces in cities; (5) condemnation of insanitary and overcrowded house property; (6) regulation of the dust danger in cities; (7) standards for factories and mines; (8) standards for public halls, theaters and public conveyances with inspection; (9) standards of sanitation for farms where dairy products are sold; (10) adequate legislation and inspection to enforce proper regulations, and wide dissemination of useful information.

E. Bureau of Pure Food.—This bureau should provide (1) standards of purity for all foods and drinkables, (2) meat and animal inspection. The beginnings of this bureau are in the Pure Food and Meat Inspection bills, now in course of agitation.

F. Bureau of National Quarantine.—The National Quarantine Act recently passed forms a precedent for such a bureau; also work done by the Public Health and Marine-Hospital Service. An appropriation of $200,000 is, however, entirely inadequate. This bureau should (1) provide means for handling epidemics with speed, (2) regulate quarantines against infectious diseases, (3) study and devise means of handling diseases transmitted by insects.

G. Bureau of Registration of Physicians and Surgeons.—This bureau should have power to require (1) that all colleges educating physicians and surgeons be under national inspection as to curriculum and training; (2) that all physicians and surgeons be required to be registered; (3) that returns be made by physicians and surgeons of records of all cases, on official blanks, showing on analysis by the department statistical records, such as average visits per illness, cases per death, etc.; that returns be made by physicians and surgeons of all organic or chronic diseases for use of the Bureau of Organic Diseases; (4) that licenses be issued barring general practitioners from treating special diseases requiring skill above that evidenced by training; (5) that the standard of the profession be raised by protecting the exceptional men and barring quacks, charlatans, etc.

H. Bureau of Registration of Druggists, Drug Stores and Manufacturers of Drugs.—This bureau should have the necessary powers (1) to regulate the standard of drugs, and to require drugs to be sold, as far as possible, in unbroken packages under seals; (2) to regulate "patent medicines" by requiring contents printed on labels, under government stamp, and severely punishing both newspapers and manufacturers for the insertion of false or fraudulent advertising matter calculated to deceive the public; (3) to regulate preparations of prescriptions by doctor and druggist, by fixing standards, and by summarily punishing substitutions; (4) to maintain competent inspectors and to enforce such regulations as shall accomplish the results; (5) to prepare and to furnish druggists, doctors, etc., with a weekly or monthly bulletin containing orders and instructions in a systematic educational campaign.

I. Bureau of Registration of Institutions of Public and Private Relief, Correction and Detention.—This bureau should investigate conditions in institutions and establish standards. The inmates should be the subject of experiments in diet, hygiene, sanitation, etc., and also of statistical inquiry. The census has recently issued a bulletin in this field.

J. Bureau of Immigration.—This bureau should include in addition to the present service, provisions for the study of races, desirable immigration, mixture of races and also distribution locally.

K. Bureau of Organic Diseases.—The data returned by physicians in compiling notifications concerning chronic and organic diseases with history should be a field for study. Means should be taken educationally (1) to ameliorate and advise by pamphlets; (2) to follow up and to study for causes and remedies; (3) to furnish practitioners with directions for treatment. Dr. Solis Cohen estimates that consumptives alone now number not fewer than 1,000,000. The importance of the work can not be overestimated.

L. Bureau of Health Information.—This bureau should adopt methods used by the Department of Agriculture, the follow-up pamphlet, etc., with a view to disseminating reliable information couched in plain language concerning right living as widely and as thoroughly as possible.

M. National Bureau of Research Requiring Statistics.—In human beings differences in habits are probably more important than difference in physical characters in determining the optimum health, and in warding off morbidity and mortality, as well as criminality. Habits should be investigated to a far greater extent than they have been hitherto. The highly exact methods of statistical analysis, involving the theories of variation, correlation and regression, should be applied to this field on a large scale. Such questions as the correlation of food habits and alcoholism with mental and physical efficiency, value of foods experimentally determined by results in connection with mental and physical efficiency rather than by laboratory theories, effects of longer or shorter labor day on efficiency, correlation of the number of open windows and cases of sickness, etc. Such questions of vital interest can be determined to a finality by the new statistical analysis. The opportunity presented by the possibility of experiment with the diet of the Army, the Navy, the inmates of houses of detention and correction, should not be lost. The preparation of all blanks in use by all other departments should be subject to the approval of this department, which should have at its head exceptional men. The vital statistics of the census should be managed by this bureau. The necessity for experts of the highest order is discussed in a subsequent section.

N. National Bureau of Research Requiring Laboratories and Apparatus.—This bureau should endeavor systematically to extend knowledge of remedies for the deadly diseases which may be advantageously pursued by laboratory methods.

The organization in vogue among modern business corporations and the practice of playing off against each other several experts engaged in independently solving the same problem should be adopted. That which can be accomplished through the organization of the world's exceptional men under the lash of failures and stimulus of great rewards is of vast magnitude.

The vital problem for the Department of Research is to make new discoveries of value at a rapid rate. New discoveries or inventions in general depend on the number of exceptional men in a society capable of such work. Exceptional men are in degrees as one in a thousand, one in a million, an Edison, one in two hundred million of a population. An art discovered by one such man becomes operative for an entire population. The necessity of employing experts can not be overemphasized. The possibilities of a civilization efficiently administered by exceptional men practically renders negative the evils of the Malthusian theory.

1. The greater the population the greater the number of exceptional men of all degrees, since exceptionality depends on a ratio to the total population.

2. The value of the work of a given exceptional man capable of producing an invention, depends on the value of the invention to the average man who uses it, multiplied by the number of users, who are in ratio to the total population.

3. Two results emerge: (a) The value of the work of an exceptional man increases directly with the growth of the population. (b) Society gains greatly through the increase in its numbers, since every member of the population on the average is served by all of the exceptional men. The value of the work of a Luther Burbank, an Edison or an Eli Whitney is incalculable.

From the standpoint of eugenics, it is desirable: (1) To select as early as possible the exceptional minds; (2) to afford these minds every opportunity of training and education; (3) to place them in operation where their exceptionality may prove advantageous to society; (4) to place in operation instantaneously the results of their work. How large are the appropriations now made for the defective children who must forever be a burden on society. How little has been done for the exceptional children who must carry by their work both the defective and the average of the population. Professional organizers understand the importance of this phase, Carnegie in his libraries and institutes, Rockefeller in the Rockefeller Institute and Chicago University. *A fortiori* the nation should provide for this necessity.

The economic reasons for establishing a National Department of Health are five:

1. To enable society to progress more rapidly under the law of increasing returns through increasing the percentage of exceptional men of each degree (many of whom are now lost through preventable accidents), in addition to increasing the total population.

2. To lessen the burden of the unproductive years on the productive years by increasing the average age at death. If we estimate the average span at 40 years, and 20 years as unproductive, the ratio of unproductive to productive years is 100 per cent. Without venturing an opinion as to the true figures after the manner of La Place, I have calculated what would be the economic gain if average span were 40, 45, 50 and 55 years and also the burden of an unproductive year at $100 and $200. The annual gains are shown under the various hypotheses. Thus if the average life-span of a class of the population can be increased from 40 to 45 years, the economic gain would be $25 to $50 per head. Assuming 40,000,000 of productive age in the United States, the burden of the unproductive years of childhood, lightened by an increase in the average life span, from 40 to 45 years would be $800,000,000 to $1,600,000,000 per annum, and an increase of ten years would result in savings of $1.320,000,000 to $2,640,000,000 per annum.

Burden of Unproductive Years on Productive Years.

Average span of life in years	40	45	50	55
At $100, per cent	100	80	67	57
Measured in dollars, per capita	$100	$ 80	$ 67	$ 57
Gain for period		20	13	10
Total gain		20	33	43
At $200	200	160	134	114
Gain for period		40	26	20
Total gain		40	66	86

3. The third economic reason for establishing a department of health is to decrease the burden of death on the productive years by increasing the age at death. If the expense of illness and death are $300, and the average age at death is 40 years, the average death expenses average $15 on the twenty productive years. Could the average age be increased to 50 years, the burden falls to $10, or a decrease of 50 per cent. For 80,000,000 of people, the saving of $1.50 per year of life would be equivalent to $120,000,000 per annum.

4. The fourth object of the plan would be to lessen the economic burden of sickness. Assuming Newholme's figure of 9 days' average illness per annum, approximately 2,000,000 years of life are lost per annum. Estimating wages at $1 a day, and all other expenses $1 a day, $1,444,000,000 loss per annum is registered by this item. Could the days of illness be cut down one-third, nearly $500,000,000 would be saved.

5. Higgins has estimated that six hundred millions are now spent on criminality in the United States. If the criminality is largely the product of the social environment, such as overcrowding, alcoholism, etc., measures which would decrease this only fractionally are worthy of consideration. A decrease of 16 2/3 per cent. would result in savings of $100,000,000 per annum.

For the last four estimates the total savings range between $1,800,000,000 and $4,000,000,000 per annum.

In addition to the economic gain, the establishment of a National Department of Health would gradually but surely diminish much of the misery and suffering that can not be measured by statistics. Sickness is a radiating center of anxiety; and often death in the prime of life closes the gates of happiness on more than one life. Let us not forget that the "bitter cry of the children" still goes up to Heaven and that civilization must hear, until at last it heeds, the imprecations of forever wasted years of millions of lives.

If progress is to be real and lasting, it must provide whatever bulwarks it can against death, sickness, misery and ignorance; and in an organization such as a National Department of Health—adequately equipped—a vast preventive machine—working ceaselessly, an attempt at least would be made to staunch those prodigal wastes of an old, yet wastrel world.

HYPERSUSCEPTIBILITY.*

M. J. ROSENAU, M.D. and JOHN F. ANDERSON, M.D.
Director and Assistant Director, respectively, of the Hygienic Laboratory, United States Public Health and Marine-Hospital Service.
WASHINGTON, D. C.

(Abstract.)

The phenomenon of hypersusceptibility has long been recognized, but has been overshadowed in modern studies on immunity. Instances of hypersusceptibility to certain infectious diseases, bacterial toxins and other substances may be found scattered through the literature. The well-known hypersusceptibility to tuberculin in animals infected with tuberculosis has received much attention, but the importance of hypersusceptibility in general pathology has not been realized.

At first glance it would appear much more important for an organism to be *hyposensitive* than *hypersensitive* to infectious processes, but a closer study of the com-

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Dr. G. F. Ruediger, Chicago, said that about a year ago he was approached on this subject of untoward symptoms following the use of antitoxin by the representative of a manufacturer of antitoxin, who showed letters indicating that the writers got their most serious results after several injections had been given. From the reports in the literature he came to the same conclusion mentioned by Dr. Rosenau: that is, that many of the most alarming symptoms are observed after the first injection. The letters showed, however, that these doctors got very alarming symptoms, with collapse in some instances, after several injections had been given and not after the first injection. These reports are not published, as a rule.

Dr. Theobald Smith, Boston, said the subject had interested him since 1902, although no special effort has been made to analyze the phenomenon. He remarked that guinea-pigs which have received no preliminary doses of serum may die and that of those which have received a fairly large dose of serum at the outset nearly all are thereafter immune. The problem, therefore, is very complicated. He presented his results in the following table:

GUINEA PIGS

Preliminary treatment	Final treatment	Number treated	Results			% of illness or death
			Died	Re-cover'd	No effect	
3cc—5cc diph. antitoxin	3—5cc diph. antitoxin	31	2	—	29	6.45
nothing	3—5cc diph. antitoxin	58	9	—	49	15.5
diphtheria toxin only	3—5cc diph. antitoxin	10	—	—	10	0
dipth. toxin + antitoxin (serum 1/200—1/400cc)	3—5cc diph. antitoxin	18	10	3	5	72.3

Dr. Smith said that an interval of two or three minutes elapsed between the first and second injections. None died after the first treatment. He did not know whether or not the animals were the young of guinea-pigs that had been treated.

Dr. Rosenau said that he wished that he could believe that Dr. Vaughan's explanation is the correct one, being so plain and succinct. It is very easy to expand Ehrlich's side-chain theory to fit these facts by adding, subtracting or modifying a receptor. Dr. Anderson and he had felt that they could safely let Ehrlich modify his own theory to include the new facts. With Dr. Vaughan he realized that chemistry may some day explain the complex and multiple processes constantly going on in living protoplasm. It seemed to him that science has not yet reached that stage where it can assign a definite chemical molecular structure to such a complex, highly-organized and changing substance as protoplasm. Those who constantly deal with the material sciences would like a physical or chemical explanation of life. A correct explanation of the phenomenon studied in the guinea-pig would bring nearer the solution of many problems connected with metabolism and the fundamental processes on which existence depends.

DETERMINATION OF THE NORMAL TEMPERATURE OF THE CLOSED INGUINAL FOLD OF A CHILD, AND ITS CLINICAL SIGNIFICANCE.*

ALBERT H. PARKS, A.M., M.D.

CHICAGO.

HISTORY.

The practitioner of medicine is constantly looking to science and research for methods he may use in his routine work. Most practitioners seek methods which combine two characteristics, accuracy and practicability, but these are often diametrically opposed. I have attempted to solve a problem in a manner that shall yield results at the same time accurate and easy of application to the clinical case.

Normal and pathologic conditions in the animal body are very intimately connected with, and in fact dependent on, the production, the distribution and the variation of that phenomenon called animal heat.

Medical and scientific literature is replete with all phases of this subject, and I intend to touch on only those points of measurement which may be included in the term thermometry.

The practitioner usually adopts the practice of taking the patient's temperature as one of the first steps in his routine examination. Two methods of estimation as pertains to clinical thermometry are in vogue, namely, the internal and the external. Both have their adherents and applications. Some writers contend that the only true measurement of the temperature of the body can be obtained from the internal cavities, while others state that external methods are sufficiently correct for purposes of clinical study.

The following table shows the results of observations by several authors who have made extended studies along these lines:

TABLE 1.

Maximum.		Minimum.		Mean.		Author and Place.
F.	C.	F.	C.	F.	C.	
99.05	37.2	97.7	36.5	98.42	36.9	Davy[1]: Mouth.
99.5	37.5	98.24	36.8	99.05	37.2	Gierse[2]: Mouth.
98.6	37.0	97.34	36.3	98.06	36.7	Hooper[3]: Mouth.
99.14	37.3	97.88	36.6	98.6	36.7	Hallman[4]: Mouth.
98.6	37.0	97.88	36.3	98.24	36.8	Clifford Allbutt[5]: Mouth.
100.4	38.	97.16	36.2	98.6	37.0	Wünderlich[6]: Axilla.
99.32	37.4	96.98	36.1	98.24	36.8	Leibermeister[7]: Axilla.
98.78	37.1	98.06	36.7	98.42	36.9	Damrosch[8]: Axilla.
99.32	37.4	96.98	36.1	98.06	36.7	Billet[9]: Axilla.
100.2	37.9	97.34	36.3	98.78	37.1	Billroth[10]: Axilla.
100.4	37.8	97.7	36.5	99.05	37.2	Turgenson[11]: Rectum.
98.78	37.1	97.88	36.6	98.24	36.8	Neuhaus[12]: Rectum.
99.14	37.3	98.42	36.9	98.78	37.1	Jaeger[13]: Rectum.
99.32	37.4	96.98	36.1	98.24	36.8	Nicol[14]: Rectum.
99.5	37.5	99.32	37.4	99.14	37.3	Hall[15]: Rectum.

The average of the mean observations in Table 1 for the mouth temperature is 98.47 F. (36.93 C.), for the axilla 98.43 F. (36.91 C.), for the temperature of the rectum 98.81 F. (37.12 C.). This shows that the difference between the mouth temperature and the axillary temperature is very small, approximately .04 F. (.02 C.). The variation between the axillary and rectal temperature is somewhat larger, being .38 F. (.21 C.). The maximum average for the temperature of the mouth is 99.42 F. (36.91 C.), the minimum being 98.47 F. (36.93 C.); for the axilla, maximum 99.60 F. (37.56 C.), minimum 98.42 F. (36.91 C.), and for the rectum, maximum 99.33 F. (37.41 C.), minimum 98.69 F. (37.05 C.).

Many authors quote higher readings, especially for the rectal temperature, and also declare that the difference between the rectal and axillary temperature is greater, while a few are under the above figures. My observations regarding rectal temperature closely correspond with the results of the above table, with the exception that the range of variation was greater, due to the fact that the temperature range of children is more variable than that of adults.

It can not be denied that for purposes of accuracy the natural closed cavities of the body give more constant and reliable results than surface temperatures, or the artificially closed cavities as the axilla, or the groin.

The surface of the body naturally responds more quickly to the variations in temperature of the surrounding medium, and in some instances the variation is considerable. For instance, in the case of rigor the surface temperature falls several degrees, while the internal temperature is steadily rising. This is further shown by the tests made during the defervescence of fevers, in which case the temperature of the blood falls, while the surface remains at fever heat. A very rapid fall of temperature in an external part likewise corresponds to a very rapid rise in the internal parts. In the vast majority of cases the external cavities of the body, as the axilla and the groin, if properly closed for a few minutes, soon approximate the internal temperature of the body.

In taking the temperature of infants, to which class of patients I now confine my attention, we are confronted by an inability to use the ordinary oral method employed so extensively in adults, and so we are forced to rely on some other means for estimating the body temperature.

METHODS.

The following methods are being used or have been suggested by various authors:

1. Internal surfaces...............rectum, vagina
2. External surfaces.................axilla, groin
3. Freshly voided urine.

The first or rectal temperature has been the accepted method and probably gives the most constant and reliable results. It has always enjoyed the greatest popularity in the practice in hospitals and institutions, while the practitioner in the private home has often made objections to it, as it is sometimes repulsive to his other patients or friends in the home. An oral temperature for the mother, following a rectal temperature for the child is likely to raise a suspicion in the mind of the former that her esthetic interests are not properly guarded by the physician. It is sometimes no justification to say that separate thermometers are kept for each purpose or that the instrument has been properly cleansed, for, in fact, that necessary procedure is sometimes neglected.

Objections are also raised to this method, as it can seldom be repeated often enough for the exigencies of many cases unless the physician is in constant attendance or is assisted by a professional nurse. It is not safe to intrust an unskilled hand with the introduction of the thermometer into the rectal cavity of an infant, for injury to the rectum has been reported in several cases from careless manipulation of the instrument both by means of force and by breakage. A rectal fistula with the introduction of septic material would present a serious condition in an infant. The rectal temperature necessitates an unnecessary exposure to cold and drafts, and is often entirely unreliable, due to contact with or the introduction of the bulb of the thermometer into a mass of feces.

Still lesss suitable is the method of taking the temperature in the vagina. The taking of the temperature of the freshly voided urine is only mentioned to be condemned.

We are left now to the consideration of the last two methods, external temperatures, taken in the temporarily closed cavities, namely, the axilla and groin. The temperature of the well-closed axilla has probably been the most used and convenient method employed by the practitioner for many years in those cases in which he did not wish, for any reason, to take a rectal temperature. The use of the thermometer in this location is not attended with many difficulties and it overcomes many of the objections to the former procedures. It is also shown by Table 1 to be approximately correct, varying from .38 F. to .21 C. from the rectal temperature.

The temperature of the groin, which has been suggested at various times by numerous authors and employed in practice by a few, possesses many advantages and gives results somewhat similar to those of the axilla. The literature to date does not give any complete records of clinical observations of temperatures taken in the groin nor does one find any description of the technic which would seem to possess many points of interest or value.

I present the following observations made on 175 individual cases: a. The age of the patients varied from 4 months to 5 years. b. Normal cases were used so far as possible. c. Mean readings were taken in all cases used as a basis for the determination of the normal temperature of the groin. d. For comparative results in the groin and rectum, individual readings were largely used without reference to number or time. e. In all observations identical conditions were obtained in each case, and these same conditions were produced so far as possible in all cases as a whole. f. The thermometers used in this work were the ordinary one-half minute self-registering clinical thermometers corrected to the same standard instrument.

TECHNIC.

The following technic was used in these cases:

I. Rectal method.
    1. The ordinary technic was used. The bulb of the thermometer was introduced well into the rectum and the readings recorded when the mercury became stationary.
    2. The child was exposed as little as possible.
II. Inguinal method.
    1. The clothing was loosened, but not removed, so as to be free from the groin.
    2. The groin was wiped dry with a towel to remove all secretions from the skin.
    3. The thermometer was placed deep in the inguinal fold and the leg allowed to return to its natural position of adduction.
    4. Readings were taken *in situ* until the maximum reading was reached.

TABLE 3.

Age.	Rectum.		Time.	Groin.		Time
	F.	C.		F.	C.	
18 months	98.8	31.1	4 min.	98.6	37.	6½ min.
1 year	99.32	37.4	3 min.	99.0	37.2	7 min.
4 years	98.06	36.7	3½ min.	97.8	36.6	5½ min.
6 months	99.1	37.3	5 min.	99.0	37.2	5½ min.
9 months	97.8	36.6	4½ min.	97.49	36.4	6 min.
4½ years	98.0	36.7	4 min.	97.6	36.5	6½ min.
2 years	98.78	37.1	6 min.	98.65	37.0	7 min.
1 year	100.04	37.8	3 min.	99.5	37.5	5½ min.
8 months	99.0	37.25	3¼ min.	98.7	37.1	8 min.
18 months	98.8	36.7	4½ min.	98.5	37.0	4¾ min.
3 years	97.9	36.6	5½ min.	97.4	36.3	6½ min.
10 months	98.05	36.7	5 min.	98.0	36.7	6 min.
4 years	99.0	37.2	3½ min.	98.4	36.9	8 min.
5 years	99.14	37.3	4 min.	99.0	37.2	5 min.
4 months	100.2	37.9	3 min.	100.0	37.8	4½ min.
18 months	98.2	36.8	3¼ min.	97.4	36.3	3½ min.
2½ years	98.42	36.9	4½ min.	98.1	36.7	5½ min.
1 year	98.6	37.0	3 min.	98.1	37.7	7 min.
10 months	99.1	37.3	3½ min.	98.9	37.1	6½ min.
3 months	97.8	36.6	4½ min.	97.6	36.4	5 min.

RESULTS.

The few cases given above in Tables 2 and 3, selected at random from the entire number, will show that the difference between internal temperature (rectum) and external temperature (groin) is comparatively small.

The results of the entire number of mean cases under observation show that the average difference between the temperature of the rectum and the closed groin is .34 F. (.18 C.) while the normal temperature of the closed inguinal fold of a child is 98.52 F. (37.5 C.). The greatest difference found in any one case was 1.5 F., while the majority of the cases ranged close to average found. In a number of readings the results of the groin and rectal readings were the same, while in a few cases the inguinal temperature was higher by a fraction of a degree. In most of these cases the lower rectal temperature was found to be due to the contact of the thermometer bulb with fecal masses. In such cases the readings were discarded as not representing the true rectal temperature.

The time element, which is an important one, was carefully worked out and recorded. It was found that with the above technic the rectal method required three and one-half minutes for a complete register of the thermometer, while the inguinal method required six and three-quarters minutes. We did not find that so long a time was necessary for correct results as some authors quote for external reading.

The clinical ease of application of the two methods offers interesting results. The great majority of cases under observation were obtained from hospitals and public institutions, and so we were not forced to face the objections which many practitioners meet with in the employment of rectal temperature. We were impressed with the great facility and ease of the inguinal method. The natural attitude of the child while retaining the thermometer in the closed groin made the usual struggling and crying unnecessary, and with but few exceptions the temperature of the groin was taken without any resistance or disturbance from the child.

It was not found necessary to hold the thermometer in the hand during the process, for the natural close apposition of the thigh to the body retained the instrument in place without any trouble, with the exception of a few cases which showed extreme emaciation. In such a condition more satisfactory results may be obtained from the internal than from the external method. If it is necessary to use the external method the groin possesses obvious advantages over the axilla.

It was not feasible to consider the influence of cold or of extreme heat on the body surface as in sudden chilling or in a rapid rise in the atmospheric temperature, as the patient was protected in all cases, but a rise of .2 F. was observed in the inguinal temperature of one child directly after a warm bath.

With the thermometer in the groin and the leg retained in apposition to the body either by the hand of the nurse or the doctor, the time required for the register of the thermometer can be employed with advantage to a further study of the case.

The inguinal method is absolutely safe for the employment of the mother or the non-professional nurse, the only requisites being an acquaintance with a few simple rules of technic and an ability to read correctly a thermometer scale.

SUMMARY.

a. The normal temperature of the closed inguinal fold of a child is 98.52 F. (37.5 C.).

b. The variation of the inguinal temperature from the rectal temperature approximates one-third of a degree F. or two-fifths of a degree C., the average variation being .34 F. (.18 C.). That is, the inguinal temperature is approximately one-third of a degree F. (two-fifths C.) below rectal temperature.

c. The usual variation between the temperature of the rectum and groin is so small as to be practically disregarded for clinical purposes.

d. The absence of many objectionable features of the rectal method and the ease and reliability of the groin method gives the latter several points of advantage over the rectal method. These advantages of the groin method would recommend it not only as applicable in hospital practice in pediatrics, but more especially in home practice among children.[16]

Skill Acquired by Long and Diligent Application.—In this day of "workless" methods of doing things, remarks the *Western Medical Review*, it will be wise to realize that there are certain ends which can only be obtained by conscientious as well as conscious efforts. There is no method of attaining skill and accuracy of diagnosis except that method which involves long and painstaking mental and manual education.

Special Article

A FORGOTTEN WORTHY, DR. DIEGO ALVAREZ CHANCA, OF SEVILLE, SPAIN.

A. M. FERNANDEZ DE YBARRA, A.B., M.D.
NEW YORK CITY.

With Christopher Columbus, on his second voyage of discovery to America, in the year 1493, there came Dr. Diego Alvarez Chanca, a distinguished practitioner of much learning and professional skill, who held the position of physician-in-ordinary to the King and Queen of Castile and Aragon, and had attended their first-born child, Princess Isabella (who afterward became Queen of Portugal) during a serious illness the year before. He was a native of the city of Seville, and had been especially appointed by the Spanish monarch to accompany that expedition, not only on account of its great political and commercial importance, but also because among the 1,500 persons who came over from Europe to America in that fleet were several distinguished personages and a large number of aristocratic young gentlemen, restless and daring warriors who had done excellent service in the war just ended against the Moors. As an able practitioner, he saved the life of Christopher Columbus, who suffered a very dangerous attack of typhus fever on one occasion and pernicious malarial fever on another occasion, as well as the lives of many Spanish hidalgos who were at the point of death as victims of disease during their stay at the island of Hispaniola or Haiti, as the aborigines called it.

The second expedition was altogether different from the one sent out the previous year in quest of a new passage to the Indies. Instead of the three small caravels, carrying only 120 persons, which accomplished the most transcendent event in the history of humanity—the discovery of the western hemisphere—this flotilla was composed of three great galleons or carracks and fourteen caravels of different sizes. It was well provided with all the requisites for the establishment of a permanent settlement in the land that had been discovered the year before. Even 20 horses for as many lancers (which played a most terrorizing influence among the American Indians) were also on board those vessels.

On their arrival at the island of Hispaniola or Santo Domingo—where the year before Columbus had left 38 men in an improvised fortress, constructed with the remains of the caravel *Santa Maria*, wrecked on the reefs of the shore—Dr. Chanca wrote in the Spanish language of the fifteenth century his famous letter to the Municipal Council or *Cabildo* of his native city, which manuscript is unquestionably the first written document about the flora, the fauna, the ethnology and the anthropology of America.

Dr. Chanca's letter was written at the port of Isabella, during the last days of January, 1494; it left that port February 2, in care of Don Antonio de Torres, commander of the twelve vessels sent back by Columbus to Spain with the news of the discoveries, and arrived there April 8, 1494.

On his return to Spain Dr. Chanca published, in the year 1506, a treatise entitled "Para curar el mal de costado," (The Treatment of Pleurisy) and a commentatorial work in Latin, criticising the book entitled "De Conservanda Juventute et Retardanda Senectute," whose author was another celebrated Spanish physician named Dr. Arnaldo de Villanova. The title of the second work of Dr. Chanca is "Commentum novum in Parabolis divi Arnaldi de Villanova," which was printed in Seville, the year 1514.

Here now follow some scattered paragraphs, translated by me from the original Spanish letter of Dr. Diego Alvarez Chanca, addressed to the municipal authorities of the city of Seville, considered by competent judges to be a most remarkable document, and the best description of the first part of the second voyage of Christopher Columbus to America. I have added a few explanatory notes:

"Since the occurrences which I relate in private letters to other persons are not of such general interest as those which are contained in this epistle, I have resolved to give you a complete narrative of the events of our voyage, as well as to treat of other matters which form the subject of my petition to you. The news I have to communicate is as follows:

The expedition which their Catholic Majesties sent, by divine permission, from Spain to the Indies, under the command of Christopher Columbus, admiral of the ocean, left Cadiz on the twenty-fith day of September, in the year 1493, with wind and weather favorable for the voyage. This wind lasted two days, during which time we managed to make nearly fifty leagues. The weather then changing, we made little or no progress for the next two days; it pleased God, after this, to restore us fine weather, so that in two days more we reached the island of Great Canary. Here we put into harbor, which we were obliged to do to repair one of the ships that made a great deal of water. We remained all that day, and on the following set sail again, but were several times becalmed, so that four or five days more passed before we reached the island of Gomera. We had to remain at Gomera one day to lay in our stores of meat, wood, and as much water to drink as we could stow, preparatory for the long voyage that we expected to make without seeing land.[1] Thus it happened that through the delay at these two ports, and being calmed the day after leaving Gomera, we spent nineteen or twenty days before we arrived at the island of Ferro.[2]

After this we had, by the goodness of God, a return to fine weather, more continuous than any fleet ever enjoyed during so long a voyage; so that leaving Ferro on the thirteenth day of October, within twenty days we came in sight of land, but we should have seen it in fourteen or fifteen days if the ship *Capitana*[3] had been as good a sailer as the other vessels, for many times the others had to shorten sail because they were leaving us much behind. During all this time we had great fortune, for throughout the voyage we encountered no storm, with the exception of one on St. Simon's eve, which for four hours put us in considerable danger.[4]

On the first Sunday after All Saints' day, namely, the third of November, about dawn, a pilot of the *Capitana* cried out: "The reward, I see land!"[5] The joy of the people was so great, that it was wonderful to hear their cries and exclamations of pleasure; and they had good reason to be delighted, for they had become so wearied of bad living, and of working the water out of the leaky ships, that all sighed most anxiously for land. The pilots of the fleet reckoned on that day that between the time of leaving the island of Ferro and first reaching land, we had made 800 leagues;[6] others said 780, so that the difference was not great, and 300 more between Ferro and Cadiz, made in all 1,100 leagues.[7] I do not, therefore, feel now as one who had not seen enough water.

On the morning of the aforesaid Sunday we saw lying before us an island, and soon on the right hand another appeared. The first was high and mountainous on the side nearest to us; the other was flat and very thickly wooded. As soon as the light of day became brighter other islands began to appear on the right and on the left of us, so that that day there were six of them to be seen lying in different directions, and most of them of considerable size. . . .

---

[1] From that island of Gomera Columbus embarked eight pigs, bulls, cows and calves, sheep and goats, fowls and pigeons, seeds of oranges, lemons, bergamots, citrons, pomegranates, dates, grapes, olives, melons and other European fruits, as well as all kinds of orchard and garden vegetables. All these were the origin of their species in the New World. The expedition likewise carried implements of husbandry, shipped before leaving Spain.

[2] This is the southwesternmost of the group of the Canary Islands, formerly called the Fortunate Islands, and is named in Spanish *Hierro*.

[3] That vessel was a galleon of 400 tons' burden, that carried the admiral's flag, and in which Dr. Chanca made the trip.

[4] They believed themselves in much peril, as they certainly were in such a sudden and fierce storm, accompanied by heavy rain, rapid lightning and great peals of thunder, which are so frequent in the tropics, until they beheld several of those lambent flames called by sailors "St. Elmo's tapers," playing about the tops of the masts and gliding along the rigging, which are occasionally seen about tempest-tossed vessels during a highly electric state of the atmosphere. The sailors consider that phenomenon as of good omen.

[5] The Spanish government had offered a reward in money to the first person who would see land in this voyage.

[6] That is to say, 2,400 Spanish miles, or about 2,057 English miles.

[7] Three thousand three hundred Spanish miles, equivalent to about 2,829 English miles.

This island of Marigalante is filled with an astonishing thick growth of wood; that variety of trees being unknown to us, some bearing fruit and some others flowers. It was surprising to see that, and, indeed, every spot was covered with verdure.

We found there a tree whose leaf had the finest smell of cloves that I have ever met with. It was in shape like a laurel leaf, but not so large; I think it was really a species of laurel.[8] There were wild fruits of various kinds, some of which our men, not very prudently, tasted; and on only touching them with their tongues, their mouths and cheeks became swollen, and they suffered such a great heat and pain that they seemed by their actions as if they were crazy, and felt obliged to resort to cooling applications to ease the pain and discomfort.[9] . . .

These islanders appear to us to be more civilized than those those who had hitherto been seen before, for although all Indians have houses made of straw, yet the dwellings of these people are constructed in a much superior fashion, better stocked with provisions, and exhibit more evidence of industry, both on the part of the men and of the women. They had a considerable quantity of cotton, already spun and prepared for spinning, and many cotton blankets, so well woven as to be in no way inferior to similar ones made in our country.[10] . . .

We were able to distinguish which of the women were natives of these islands and which captives, by the distinction that a Caribbee woman wore on each leg two bands of rings of woven cotton, one fastened around the knee and the other around the ankle, by this means making the calves of their legs look big and the above-mentioned parts small, which I imagine they do because they believe this sort of adornment makes them pretty and graceful; by that peculiarity we distinguish them.

The captive women told us that the Caribbee men use them with such cruelty as would scarcely be believed; and that they eat the children which they bear to them, only bringing up those which they have by their native wives. Such of their male enemies as they can take away alive, they bring here to their homes to make a feast of them, and those who are killed in battle they eat up after the fighting is over. They claim the flesh of man is so good to eat that nothing like it can be compared to it in the world; and this is very evident, for of the human bones we found in their houses everything that could be gnawed had already been gnawed, so that nothing else remained of them but what was too hard to be eaten. In one of the houses we went in we found the neck of a man undergoing the process of cooking in a pot, preparatory for eating it.[11]

The habits of these Caribbees are beastly.

There are three islands: this one on which we are is called by the natives Turuqueira;[12] the other, which was the first we saw, is named Cayre,[13] and the third Ayay.[14] There is a general resemblance among the natives of these three islands, as if they were of the same lineage. They do no harm to one another, but each and all of them wage war against the inhabitants of other neighboring islands, and for this purpose sometimes they go as far as 150 leagues in their canoes,[15] which are a narrow kind of boats, each made out of a single trunk of a tree. Their arms are arrows, in place of iron weapons, and as they have no iron, some of them point their arrows with a sharpened piece of tortoise-shell, and others make their arrow heads of fish spines, which are naturally barbed like coarse saws. These arms are dangerous weapons only to naked people like the Indians, causing death or severe injury, but to men of our nation they are not much to be feared.[16] . . .

When the Caribbees take any boys as prisoners of war, they cut off their male organs, fatten them until they grow up to manhood and then, when they wish to make a great feast, they kill and eat them up, for they say the flesh of boys and women is not good to eat. Three of those boys thus mutilated came fleeing to us when the visited the houses.[17]

The difference between these Caribbees and the other Indians, with respect to dress, consists in wearing the hair very long, while the others have it clipt irregularly; also because they engrave in their heads innumerable cross-like marks and different devices, each according to his fancy; and they make those marks with sharpened bamboo sticks. All of them, both the Caribbee and the other Indians, are beardless, so that it is a marvellous thing to find one of these men with a beard. The Caribbees whom we have taken prisoners, have their eyes and eyebrows stained circularly around, which I think they do for ostentation, and also because it gives them a ferocious appearance. . . .

Here almost terminate the group of islands, which on the side toward Spain had not been seen before by the Admiral,[18] although we regard, as a matter of certainty, that there is land more than forty leagues beyond the southernmost of these newly-discovered islands.[19] We believe this to be the case, because two days before we saw the first island[20] we had observed some birds called "rabihorcados," which are marine birds of prey that do not sit nor sleep on the water, making circumvolutions high up in the air at the close of evening, with the object of taking their reckoning of where they are and flying after that in a straight line towards land to sleep.[21] These birds could not have been going to spend the night at more than twelve or fifteen leagues' distance from where they were, because it was already late in the evening, and the direction they took in their flight was toward the south. From all this we concluded there was land in that direction still undiscovered; but we did not go in search of it because it would have taken us out of our intended route. I hope that in a few more voyages it will be discovered.[22] . . .

---

[8] Probably it was the *Kalmia angustifolia* or "Laurier des Montagnes," as it is called in the French West India Islands.

[9] I believe those poisonous fruits were a species of small apple called in Spanish *manzanillo,* or in English manchineel tree (*Hippomane mancinella*), which is still to be found in the West India Islands. The fruit of the manchineel tree produces similar effects to those here described by Dr. Chanca, also vomiting and purging. The shadow cast by the foliage of this wild tree raises a blister on the skin, the same as the guao (*Rhus metopium*), which is a wild shrub, very abundant in the Antilles.

[10] The Caribbee Indians possessed also the art of making household utensils of clay, which they baked in kilns like the potters of Europe.

[11] Mr. Justin Winsor, the accomplished librarian of Harvard College, in his "Christopher Columbus," referring to the Caribbee Indians, makes the following interesting remarks: "The contiguity of these two races, the fierce Carib and the timid tribes of the more northern islands (the Lucayans) has long puzzled the ethnologist. Irving indulged in some rambling notions of the origin of the Carib, derived from observations of the early students of the obscure relations of the American peoples. Larger inquiries and more scientific observations since Irving's time have been given to the subject, still without bringing the question to recognizable bearings. The craniology of the Caribs is scantily known, and there is much yet to be divulged. The race in its purity has long been extinct. Lucien de Rosny in an anthropologic study of the Antilles published by the French Society of Ethnology in 1886, has amassed considerable data for future deductions."

[12] This was the island of Guadeloupe, named by Columbus *Nuestra Senora de la Guadalupe,* in remembrance of the famous sanctuary of Our Lady of Guadalupe, in the province of Extremadura, Spain.

[13] This was the island of Dominica, so called by Columbus from having been discovered on a Sunday (*Dies Dominica*). It is 29 miles long and 13 miles in its greatest breadth, situated at 15 degrees 25 minutes north latitude and 61 degrees 15 minutes west from Greenwich Observatory. It has an area of 291 square miles and belongs to England.

[14] This must have been the island now known as Martinique, though Dr. Chanca does not mention in his letter having been there. It is situated 30 miles south by west of the island of Dominica and 20 miles north of the island of St. Lucia.

[15] That is to say, 450 Spanish miles, or about 376 English miles, which means as far as Porto Rico, Santo Domingo and Cuba to the North, and Trinidad, Curaçao and the coast of South America to the South.

[16] Dr. Chanca did not know at that date that the arrow points of the Caribbees were poisoned with the juice of a plant, probably the inspissated sap of the manchineel tree.

[17] Herr Alexander von Humboldt, in his "Personal Narrative of Travels to the Equinoctial Regions of America," speaking about the Caribbees, makes the following instructive observations: "Reproaches addressed to the natives on the abominable practice which we here discuss, produce no effect; it is as if a Brahmin, traveling in Europe, were to reproach us with the habit of feeding on the flesh of animals. In the eyes of the Indian of the Guaisia, the Chernvichæna was a being entirely different from himself, and one whom he thought it was no more unjust to kill, than the jaguars of the forest. It was merely from a sense of propriety that, while he remained in the mission, he would eat only the same food as the fathers. The natives, if they return to their tribe (*irse al monte*), or find themselves pressed by hunger, soon resume their old habits of anthropophagy. And why should we be so much astonished at this inconstancy in the tribes of the Orinoco, when we are reminded, by terrible and well-ascertained examples, of what has passed among civilized nations in times of great scarcity? In Egypt, in the thirteenth century, the habit of eating human flesh pervaded all classes of society; extraordinary snares were spread for physicians in particular. They were called to attend persons who pretended to be sick, but who were only hungry; and it was not in order to be consulted, but devoured. An historian of great veracity, Abd-allatif, has related how a practice, which at first inspired dread and horror, soon occasioned not the slightest surprise."

[18] Dr. Chanca refers here to the island called by the aborigines Borinquen, which is the island we know to-day as Porto Rico, and named by Columbus San Juan Bautista (St. John the Baptist). The date of its discovery was Saturday, Nov. 16, 1493. There ended the Caribbee Islands, the first account of whose fierce and savage inhabitants was received with eager curiosity by the learned of Europe.

The country is very remarkable, and contains a vast number of large rivers and extensive chains of mountains, with broad, open valleys, and the mountains are very high. It does not look as if the grass is ever cut throughout the whole year. I do not think that they have any winter here, for at Christmas we found many bird-nests, some containing the young birds and the others the egg. No four-footed animal has ever been seen in this, nor in any of the other islands, except some dogs of various colors, as in our country, but in shape and size like lap-dogs. Of wild, ferocious beasts, there are none.[23]

I came near forgetting to mention another four-footed little animal, in the color of its hair, size, and fur, like a rabbit, but with long tail and feet similar to those of a rat.[24] These animals climb up the trees,[25] and many of our men who have eaten them say their taste is very good. There are many snakes, small in size, also lizards, but not so many, for the Indians consider them as great a luxury as we do pheasants. These lizards are of the same size as ours, but different in shape. In a small adjacent island, close by a harbor, which we named Monte Cristo, where we stayed several days,[26] our men saw an enormous kind of lizard, which they said was as large around the body as a calf, and the tail shaped like a lance.[27] They often went out to kill it, but bulky as it was it disappeared in the thicket and got into the sea, so that they could not catch it. . . .

There are, both in this and in the other islands, an infinite number of birds like those we have in our country, and many others, such as we had never seen. No kind of domestic fowl has been found here, with the exception of some ducks in the houses of the island Turuqueira. Those ducks were in size larger than the ones we have in Spain, though smaller than geese, very pretty, with flat crest, and most of them as white as snow, but some also black. . . .

Fish is abundant here, an article of food of which we were in great need, for our provision of meat was running short, and it is a singualr kind of fish, more wholesome than those we have in Spain. The climate does not allow the fish to be kept from one day to another, for all animal food speedily becomes unwholesome on account of the great heat and dampness. . . .

Large quantities of vegetables have been planted, and they certainly attain a more luxuriant growth in eight days here than they would in Spain in twenty.

We are frequently visited here by a great number of Indians, accompanied by their caciques, who are their captains or chiefs, and many women. They all come loaded with *ages*, a sort of turnip, very excellent food, which they cook and prepare in various ways. This food is very nutritious, and has proved of the greatest benefit to us all after the privations we endured when at sea, which in truth were more severe than man ever suffered. . . .

The little time that we have spent on land has been so much occupied in seeking a place to establish the settlement,[28] and in providing ourselves with things we needed,[29] that we have had little opportunity of becoming acquainted with the natural productions of the soil. In spite of this drawback, we have already seen many marvellous things. For instance: trees bearing wool, of a sufficiently fine quality (according to those who are acquainted with that industrial art) to be woven into good cloth.[30] And of this kind of tree there are so many, that we might load our vessels with wool, though it is somewhat difficult to gather it because these trees are very thorny, but some means can easily be found to overcome that difficulty.

There are also cotton trees as large as peach trees, which all the year round produce cotton, and in abundance.[31] We found trees which produce wax, as good both in color and smell as bees-wax, and equally useful for burning; indeed, with very little difference between the one and the other.[32] There is a vast number of trees which yield surprisingly fine turpentine.[33] Tar is found in abundance, of very good quality, too.[34] We discovered trees which, in my opinion, bear nutmegs, but at present without fruit on them, and I say so because the bark tastes and smells like nutmegs.[35] I saw one root of ginger, which an Indian was carrying around his neck.[36] There is aloes too, though not of the same kind as the one we are acquainted with in Spain, but, nevertheless, a species of aloes that we doctors use.[37] A sort of cinnamon has likewise been found, but, to speak truthfully, it is not of such a fine quality as the one we have in Spain; or, perhaps, this is so because now it is not the proper season to gather it, or the soil in which it was found growing in this vicinity is not well adapted.[38] We have also seen here some yellow mirabolans.[39] At this season they are lying under the trees, and as the ground is very damp they are all rotten, and have a very bitter taste, due, in my opinion, to their state of decomposition; but the flavor of those parts which in spite of that have remained sound, is the same as that of the genuine mirabolan. There is, besides, very good kind of mastic.[40] . . .

---

[19] It is truly admirable how nearly exact was this calculation of Dr. Chanca, for the comparatively large island of Trinidad, and the north coast of Venezuela, are about that distance from Martinique, the southernmost of those just discovered islands.

[20] The island of Dominica.

[21] They were frigate or man-o'-war birds (*Tachypetes aquila*), a peculiarity of which is that they persecute and compel the much larger marine birds, common pelicans (*Pelicanus onocrotalus*), to throw up what they have swallowed, and eat it themselves.

[22] And that land was in fact discovered, as predicted by the learned author of this important historical document, in the very next voyage of Columbus. On July 31, 1498, he discovered the island of Trinidad and caught a glimpse of *terra firma* at the delta of the Orinoco river.

[23] The cayman and the crocodile are the most dangerous animals found.

[24] This little animal is the *hutia* or *jutia*, as it is called in Spanish after its Indian name, a sort of mountain rat still plentiful in those islands. There are two distinct varieties: one, large in size, called *jutia conga* (*Capromys Fournieri*), and the other, small in size, named *jutia carabali* (*Capromys Poeyi*).

[25] The present poor country people of those islands roast and eat them the same as little pigs, and their taste is really good. During the recent struggle for independence in Cuba, the patriot soldiers were compelled, on account of the scarcity and poor quality of their armament, together with lack of ammunitions of war, to live in the woods, and there they killed almost all the jutias to provide themselves with food.

[26] This small island is called now Cabras or Goat Island.

[27] This big kind of lizard was nothing else but an alligator, which is the corrupted English word from the Spanish *el lagarto* (*Alligator lucius*).

[28] They found at last a convenient place, in the selection of which the professional advice of Dr. Chanca was duly consulted. It was on the shore of a good bay on the north coast, on high ground, with two rivers of potable water near by, and the back part well closed by the thick growth of an impassible forest that protected it from being set on fire by the Indians on a night attack. There in that spot was immediately commenced the building up of the very first Christian town of the New World, to which Columbus gave the appropriate name of Isabella, his great protectress. The ruins of the stone buildings in a solitary waste constitute to-day the melancholy relic of that historical locality.

[29] The principal of those things needed were fresh vegetables and fish, and the expeditionists soon got them. The vegetable gardens planted were speedily clothed in green, producing plentifully onions and pumpkins, radishes and beets. Sugar-cane, the first ever planted in American soil, and brought by those colonizers from the Canary Islands, had also been sown, and came up splendidly.

[30] The tree to which reference is made here is called *ceiba* in Spanish, *pojot* in the French West India islands, and "five-leaved silk-cotton-tree" in English (*Bombax ceiba*, Lin.). It grows to an immense size, is beautiful in appearance, and has its seeds enveloped in a cottony substance, light as feather, which fly in the air to a great distance.

[31] Probably the species known now as Sea Island cotton, still to be found wild in some localities in Cuba, Porto Rico and Santo Domingo. All varieties of *Gossypium* require a dry and sandy soil, and generally the plant flourishes most luxuriantly near the sea-coast.

[32] This tree is the wax-palm (*Ceroxylon andicola*), the stem of which is covered with a secretion consisting of two-thirds resin and one-third wax.

[33] One of those trees, besides the many varieties of pine-trees (genus *Pinus*), was called by the native Indians *hóbo* or *jóbo* (*Spondias lutea* or *Décandrie pentagynie*), which is the "mombain" with yellow fruit of the French botanists, a bulky tree belonging to the *Terebinthaceæ* family, very abundant in the Antilles and resembling somewhat the cedar.

[34] More correctly asphalt or mineral pitch, of which there are several lakes in the Antilles, notably the one in the island of Trinidad, about three miles in circumference.

[35] A species of *Myristica*, but certainly not the Myristica moschata of the Molucca islands. Probably it was the tree called by the aborigines *caumaná*, whose leaves have a smell like that of fennel, the bark a sweet taste, and in general appearance resembles the nutmeg tree.

In our present position, we are in the neighborhood of many mines of gold, not any one of which, we are told, is more than twenty or twenty-five leagues off. The Indians say that some of them are in Niti, a place in the possession of Caomabó, that Indian king who killed the Christians;[41] other mines are located in another place called Cibao, which, if it please God, we shall see with our own eyes before many days have passed; indeed, we should go there at once were it not because we have so many things to attend to that there are not enough men among us to do it at present. And this is in consequence of one-third of our people having fallen sick within four or five days after we landed here, which misfortune, I think, has happened principally on account of the toil and privations of the journey, to which must be added the variableness of the climate;[42] but I trust in our Lord to be able to restore all the sick to health.[43]

None of the natives of all these islands we have visited possess any iron. They have many implements, also hatchets and axes, all made of stone, which are so handsome and well finished that it is a wonder how they can contrive to make them without employing iron. . . .

Their principal food consists of a sort of bread made of the root of a herb, half way between a tree and grass,[44] and the *age*, which I have already described as being a kind of turnip, and a very good food certainly it is.[45] They use, to season it, a vegetable called *agi*,[46] which they also employ to give a sharp taste to the fish and such birds as they can manage to catch, of the infinite variety there are in this island, dishes, all of them, that they prepare in different ways. They have, besides, a kind of grain, in appearance like hazelnuts, very good to eat.[47] They eat all the snakes, lizards, spiders, and worms that they find on the ground, so that, according to my judgment, their bestiality is greater than that of any beast on the face of the earth. . . .

The admiral had, at one time, determined to leave the search for the mines until he had first dispatched the ships that were to return to Spain, on account of the great sickness which had prevailed among our men;[48] but afterward he resolved to send two detachments under the command of two captains, one to Cibao,[49] and the other to Niti,[50] places where, as I have already stated, Caonabó lived and ruled. These two detachments in effect departed, and one of them returned on the twentieth of the month, while the other did so on the following day. The party that went to Cibao saw gold in so many places that one scarcely dares to state the fact, for, in truth, they found it in more than fifty brooks and rivers, as well as on their banks; so that the captain said that anybody who wished to seek for gold throughout that province, would be sure to find as much as he wanted. He brought with him specimens from the different localities, that is to say, from the sand of the rivers and their banks.[51]

It is generally believed that by digging as we know how, the gold will be found in greater compact masses, for the Indians neither know how to dig nor have they any means of digging the ground more than to a hand's depth. The other captain who went to the place called Niti, returned likewise with news of a great quantity of gold found in three or four localities, of which he also brought some specimens with him.[52] Thus, surely, the King and Queen may henceforth regard themselves as the most prosperous and wealthy sovereigns on earth, because never yet, since the creation of this world, has such a thing been seen or read of. On the return of the ships on the next voyage, they certainly will be able to carry back such a quantity of gold as will fill with amazement all who hear of it.

Here I think I shall do well to break off my narrative. And I believe that those who do not know me, and hear of these things that I relate to you, may consider me prolix and somewhat an exaggerator, but God is witness that I have not exceeded by one iota the bounds of truth."

2164 Fifth Avenue.

EDITOR'S NOTE: Dr. Carl H. von Klein, Chicago, gives us the following additional information:

Dr. Chanca was appointed physician to Columbus' fleet on his second expedition by a dispatch of May 23, 1493. And on May 24 the chief accountants were instructed to pay him

---

36. Truly, this must have been the dry, wrinkled rhizome of the ginger-plant (*Zinziber officinalis*), so well known in Jamaica.

37. The species called Barbadoes aloes (*Aloes hepatica*), which is still considered of an inferior quality to *Aloes socotrina*.

38 That was probably the wild American cinnamon (*Nectandra cinnamoides*), or perhaps the white cinnamon of Winter (*Canella alba*).

39. They most likely were the fruit of the *Myrabolanus citrino* of Gartner.

40. A valuable resin exuding from the mastic-tree (*Pistacia lenticus*).

41 This Indian chief was a Caribbee by birth and ruled over the province of Hispaniola, called by the natives *Mangana*, in which were the mountains named Cibao. He was the cacique who killed the 38 men left by Columbus in that island on his return to Spain from his first voyage of discovery to America.

42. The climate suddenly changes in those West India islands from being very hot and dry to comparatively cool and very damp, due to long-continued and heavy rain.

43. Columbus himself was also sick with malarial fever for a few days, and seven months later suffered a dangerous malady, which I have ventured to diagnose as typhus or "ship fever" in my monograph on "The Medical History of Christopher Columbus," (which is the first and only one existing), read before the First Pan-American Medical Congress, held at Washington, D. C., in 1893, and published in the English language in THE JOURNAL A. M. A., May 5, 1894, and in the Dublin Jour. Med. Sci., August and September, 1894. It has also been published in other languages.

44. I think Dr. Chanca alludes here to the maize or Indian corn (*Zea mays*), of which the aborigines of Hayti made a kind of bread.

45. This farinaceous root is the *yuca*, called in English yucca or Adam's needle, also known as Barbadoes nut, a fibrous tuber, very esculent, of which there are in the West Indies two well-known kinds, the sweet (*Yucca gloriosa*) and the sour (*Yucca filamentosa*), this last one being cathartic and somewhat poisonous. It contains a large quantity of starch, which is obtained from the juice of the grated yucca, and from the fibrous residue is prepared the *casabe* or cassava (a corruption of the Spanish word) in the shape of very large, round and thin sort of crackers, called in Spanish *tortas de casabe*. This old kind of Indian bread is still made in Cuba, Porto Rico, Santo Domingo, etc., and is very much relished.

46. Red pepper, called *chili* in Mexico (*Capsicum frutescens*).

47. It was not a grain at all, but the palmiche (in Spanish), which is the small nut of the royal palm-tree, growing in bunches like the fruit of the date-palm. It is very much used in Cuba, Porto Rico, Santo Domingo and the other West India islands to fatten pigs with. Very likely the Indians ate it as food, and from that fact Dr. Chanca got his notion of its being a grain. Really, that nut looks like a small, green hazel-nut.

48. The expeditionists in great number were suffering from malarial fevers, about one-third of them, as Dr. Chanca states. That disease was in those days very little known, and much less its prevention and treatment. The miraculous *pulvis febrifugus orbis americani*, also called then with the names of "Jesuits' powders" and "Countess's powders" (*los polvos de la condesa*), were not yet known to Europeans. The existence, and the wonderfully curative virtue of the mysterious "quinquina" (a corruption of the indigenous Peruvian word *kina-kina*, which signifies "the bark" *par excellence*, and was the remedy that saved the lives of Charles II of England, Louis XIV of France, and Friedrich the Great of Germany, was then only known to the aborigines of the undiscovered kingdom of Peru.

49. In the Lucayan language that word meant "stone mountain."

50. The fertile valley later called by the Spaniards *La vega real*.

51. One of those specimens of gold was a nugget that weighed 9 ounces.

52. Those specimens of gold from the valley called Niti were fewer in number and of less value than the ones brought out from the mountains of Cibao. The captains of those two small detachments of Spanish soldiers were two brave young hidalgos, one named Alonso de Ojeda, who started with only fifteen soldiers, and the other, Ginés de Gorbalán, who was sent back to Spain by Columbus right after his return from this expedition to Niti, as a witness of the marvelous richness of Hispaniola. He took away with him to Spain the large nugget of gold weighing 9 ounces.

salary and rations as scrivener in the Indies. He became the physician of the colonies, for which Columbus credited him in his memorial to the monarchs as doing good service in his profession at a sacrifice of a large emolument which his practice brought to him in Seville. It is principally through Dr. Chanca that we have any history of Columbus' second voyage. He wrote a letter on the history of the voyage, which was sent by him to the Cathedral Chapter of Seville. The original is thought to be lost, but Navarrete in his "Historia de la Reyes Catolicos," in 1825, copied a transcript which belonged to a collection formed by Father Antonio de Aspa, a monk at the monastery of the Mejorada, where Columbus is known to have deposited some of his papers. The transcript is now in the Royal Academy of History, Madrid. Navarrete quotes a letter from Columbus to the king in reference to Dr. Chanca as it appears in a work entitled "Commentum in parabolis divi Arnoldi de Villanova ad illustris-simum, etc.," Sevilla, 1514, in fol. It read as follows:

"You will inform their Highnesses of the continual labor that Doctor Chanca has undergone, from the prodigious number of sick and the scarcity of provisions, and that, in spite of all this, he exhibits the greatest zeal and kindness in everything that relates to his profession. As their Highnesses have entrusted me with the charge of fixing the salary that is to be paid to him while out here (although it is certain that he neither receives, nor can receive anything from anyone, and does not receive anything from his position equal to what he did and could still do in Spain, where he lived peaceably and at ease, in a very different style from what he does here; and, although he declares that he earned more in Spain, exclusive of the pay which he received from their Highnesses), I have, nevertheless, not ventured to place to the credit of his account more than 50,000 maravedis per annum, as the sum which he is to receive for his yearly labor during the time of his stay in this country. I beg their Highnesses to give their sanction to this salary, exclusive of his maintenance while here; and I do so, because he asserts that all the medical men who attend their Highnesses in the royal yachts, or in any of their expeditions, are accustomed to receive by right the day's pay out of the annual salary of each individual. Let this be as it may, I am informed for certain, that on whatever service they are engaged, it is the custom to give them a certain fixed sum, settled at the will and by order of their Highnesses, as compensation for the said day's pay. You will, therefore, beg their Highnesses to decide this matter, as well with respect to the annual pay as to the above-mentioned usage, so that the said doctor may be reasonably satisfied."

The following reply was made to Columbus' letter: "Their Highnesses acknowledge the justice of Doctor Chanca's observations, and it is their wish that the Admiral shall pay him the sum which he has allowed him, exclusive of his fixed annual salary. With respect to the day's pay allowed to medical men it is not the custom to authorize them to receive it, except when they are in personal attendance on our Lord, the King." Nothing is known of the previous life of Dr. Chanca. The contribution of Dr. Ybarra will add a valuable page to the medical history of America.

Clinical Notes

INTRASACCULAR SUTURE OF ANEURISMS.

W. O. BULLOCK, Jr., M.D.
LEXINGTON, KY.

It is now four years since Matas, of New Orleans, gave to the profession the result of his reasoning and experience in the treatment of aneurisms. Proceeding on well-known grounds that serous surfaces, when brought together and held together will form adhesions, and that these adhesions in time become firm and unyielding, the intima of all vascular structures being made up of endothelium or rather lined with it, it was thought and subsequently proved by him that this membrane would behave in the same way as does the peritoneum, the adhesive properties of which enable the surgeon to perform many operations on the abdominal viscera which would otherwise be impossible. The chief question to be settled before the principle could be generally adopted was: Are the adhesions so formed strong enough to resist the blood pressure behind them? This point can only be settled by the combined experience of surgeons, and this is my reason for making this report.

My own experience with the operation of suture within the sac of the aneurism now includes four cases, three of which have already been made public.[1] A fourth case more fully reported herein completes my list. Before taking up the last one of my series, however, I shall review briefly my previously reported cases.

HISTORIES OF PREVIOUS CASES.

Case 1.—Traumatic fusiform aneurism of femoral artery.

Patient.—E. C., colored, aged 35.

History.—A wagon passed over the thigh in September, 1902, and symptoms began shortly afterward.

Operation.—The patient was operated on Feb. 23, 1903. A large aneurism of the femoral artery the size of a cocoanut was found. There were two openings in the bottom of the sac, separated by about an inch. The operation of intrasaccular occlusion was carried out step by step according to the original directions of the author of the method. No. 2 chromic gut sutures were used to close the vessels and for reinforcing sutures. There was a mild infection of the skin incision.

Postoperative History.—The leg and foot were warm and painless; there were no symptoms of impaired circulation. The patient was well fourteen months after operation.

Case 2.—Pathologic fusiform aneurism, popliteal artery.

Patient.—B. B., colored, aged 50, was a porter in a stove store and was accustomed to lift heavy weights.

History.—There was no definite history of injury. The first symptoms appeared eighteen months before operation.

Operation.—On June 4 the patient was operated on. The sac held about a quart of blood; the sac wall was thick and friable. There were two openings within the sac, separated by about an inch. The tourniquet broke during the operation and an extemporized tourniquet was made of the irrigator tube. The openings in the sac were closed by suture. The openings were on the outer wall of the sac nearer the superficial than the deep surface. A slight variation was necessary in the subsequent technic, due to the eccentric location of the vascular orifices.

Postoperative History.—The wound was dressed on the third day. Temperature was 104 and suppuration was profuse, coming from within the sac. Drainage was instituted and this gradually subsided. The wound healed in four weeks. There was no swelling or coldness or other symptom of impaired circulation in the leg or foot. This man is well to-day, never having had any trouble with his leg since leaving the hospital. Infection in this case was due to faulty sterilization after using the unsterilized irrigator tube.

Case 3.—Traumatico-pathologico-fusiform aneurism of the popliteal artery.

Patient.—W. B., colored, aged 34, a laborer, gave a history of syphilis. There was no distinct history of trauma. Tumor and pulsation were noticed three or four months before admission to the hospital.

Operation.—The Matas operation was performed July 29, 1904. The tumor was small, about the size of a goose egg. There were two openings on the inner wall of the sac, and these were sutured with No. 1 chromic catgut. The same variation as in Case 2 was used in this case. The sac wall was thick and friable in this case also.

Postoperative History.—The case ran an afebrile course. The wound healed by primary union. Some swelling of the leg persisted for two months after leaving the hospital. This patient is well to-day.

---

[1] Amer. Med., Aug. 29, 1903; Trans. Amer. Surg. Assoc., 1905. In a report by Dr. Matas.

HISTORY OF PRESENT CASE.

CASE 4.—Traumatico-pathologic aneurism, femoral artery.

Patient.—D. C., colored, aged 65, stated that during the Civil War he had syphilis. Arteries were moderately hard.

History of Aneurism.—He states that about a month before admission to the hospital he noticed a small lump, about the size of the end of his thumb, in the upper inner front part of his right thigh; he says that it was rather painful, but that it did not keep him from his work. He says also that there was no apparent increase in its size until one of his fellow workmen fell against his thigh; it then began to grow very rapidly and became very painful. This was about two weeks ago. Dec. 28, 1905, there was a large pulsating tumor, somewhat irregular in form, measuring 4x5 inches in its greatest diameters, the long diameter being transverse.

Jan. 8, 1906. The tumor was considerably enlarged since last examination; it consisted distinctly of two parts, divided by a slight, nearly vertical groove, the inner part being larger and more diffuse, the outer part more prominent. Approximate measurements at this time were: Longest vertical measurement, 4½ inches; longest transverse, 6½ inches.

Operation.—Jan. 8, 1906, an incision nearly vertical was made over constriction between masses of the tumor. The constriction was found to correspond to the inner border of the sartorius muscle. This was pulled aside, the sac incised and a quart or more of blood and fibrin turned out. The sac was cleansed and scrubbed. The sac walls were indefinite. Openings were sought and proximal opening was found at the upper end of the incision, hardly more than a quarter of an inch beneath the skin; it had been slightly cut in opening the sac. The intima had become detached from the middle coat and looked like a vein within the lumen of the artery, protruding slightly beyond it. An attempt was made to tie this separately, but the ligature cut through. The distal opening was found fully two and a half inches away from the proximal opening, lying slightly deeper, but presenting nothing unusual in appearance. The openings were then closed by chromic gut sutures and reinforced. On account of the openings being so superficial, the incision was greatly narrowed when these were closed. Approximation of the inner part of the sac was accomplished by retention sutures of chromic gut, four in number, passed from skin to sac, through floor of sac, back through the skin and tied over gauze pads. The outer part of the sac was not so treated, because of its small size and because I thought that compression from without would accomplish the desired result. Hemostasis was perfect. The incision was closed without drainage.

Postoperative History.—The patient's temperature and pulse were normal throughout. The wound was dressed on the seventh day and two or three drams of seropurulent fluid escaped. This was found to come from the outer part of the sac, or that part which had not been occluded by retention sutures. A gauze drain was inserted and the wound redressed daily, as the discharge in a few days had become entirely purulent. Twenty-one days after the operation the discharge had ceased and the wound healed. There was never any symptom of impaired circulation.

Feb. 22. 1906. Patient has been home three weeks and reports himself "well."

July 6, 1906. Patient is well.

DISCUSSION OF OPERATIVE PROCEDURES.

For convenience of consideration, it may be stated that the method of intrasaccular suture of aneurisms has developed three distinct procedures: 1. Intrasaccular occlusion, the Matas operation; 2. Intrasaccular repair; 3. Intrasaccular reconstruction.

1. Intrasaccular occlusion is, in most cases, the method of choice, being adapted to fusiform aneurisms or those presenting two openings within the sac, also to those sacculated aneurisms in which the single opening is very large. It is the method first employed by Matas and the method from which the other two are derived. The distinctive features of this operation consist in closing the mouths of the artery within the sac by means of closely placed catgut stitches, reinforcing the same by a Lembert suture embracing the walls of the sac, and finally, by bringing together all of the remaining sac wall and holding it together by means of retention sutures. This method has been so successful on the face of the returns that there seems but little excuse for any derivative operations except on theoretical grounds.

2. Intrasaccular repair, as its name would indicate, is the application of intrasaccular suture to the repair of the ruptured artery. It is applicable only to sacculated aneurisms, or to those presenting a single opening within the sac. It consists in closing the opening of the artery into the sac by means of Lembert sutures, and encroaching on the lumen of the vessel by utilizing the sac wall contiguous to the opening for this purpose.

This operation is applicable to both true and false aneurisms, and the record of five cases so treated without any of the usual unfavorable sequelæ would seem to show conclusively that this operation has a place in the treatment of aneurisms.

I mentioned false aneurisms because sacculated aneurisms of directly traumatic origin (gunshot wounds, stab wounds, etc.) belong usually to this class. Leave these cases alone, and if they do not bleed to death, the cells of the connective tissue confining the hematoma will take on endothelial characters and there will be formed an aneurismal sac, a false one it may be, but one that will adapt itself to plastic usages.

3. Intrasaccular reconstruction is the third procedure. In some cases of fusiform aneurisms, those having two openings within the sac, the advisability of attempting to restore the arterial wall was, and is still under consideration by some. In reporting my first case of aneurism treated by endoaneurismorrhaphy, I disapproved of such attempts on theoretical grounds. This adverse opinion has been strengthened by my further observation of the interiors of aneurisms and by the failures of attempts as reported by Matas, himself, in his collection. To my mind it is irrational to conceive that by sewing together the remains of a deceased, worn-out, broken-down vessel, one is going to get an artery. Follow the so-called successful cases and in all, unless as may happen, a thrombus forms at the site of the suture I predict recurrence sooner or later. The suggestion that reconstruction of the parent trunk in cases of fusiform aneurisms may be tried as a temporizing expedient. seems to me to be contraindicated, unless it be in cases of abdominal aneurisms; but even here I should prefer to occlude. I should not be surprised at any time to learn that the abdominal aorta had been successfully occluded by intrasaccular suture. I certainly believe that intrasaccular occlusion offers most to the victims of aneurism of the abdominal aorta. Again, as regards intrasaccular reconstruction, I regret that this method was ever suggested by the author of endoaneurismorrhaphy because the failures which are bound to follow the one will keep the other from at once occupying the place it deserves. Careless reviewing in the medical journals is responsible for many misconceptions as regards intrasaccular suture; a glaring example of such misunderstanding is to be found in an article[2] by O. von Frisch on the treatment of peripheral aneurisms, in which, after giving the results in nineteen cases operated on in the clinic of Professor von Eiselsberg, he divides the treatment into non-radical and radical. The Matas method is classed as non-radical and is disposed of thus:

---

[2] Archiv. f. klin. Chir., vol. lxxix, No. 2, 1906.

"Von den in neurer Zeit empfohlener Operationsmethoden verdient die von Matas angegebene, wonach die Gerinnsel aus dem Aneurisma entfernt werden und aus dem Rest des Sackes mit Catgutnaht ein neues Arterienrohr gebildet wird, durch das Bestreben die normalen Verhaltnisse wieder herzustellen, besondere Aufmerksamkeit."

The reviewer regards the method as irrational and unsafe. The report in itself is interesting as showing the results obtained by a single operator, employing methods other than intrasaccular suture, viz. ligation, or extirpation or some modification thereof. The number of cases treated was 19; gangrene occurred in 2 cases; local necrosis in 4; contraction of knee in 1; not heard from, 3; recurrence, 1; death, 1.

Compare this with the results obtained in thirty cases of aneurisms treated by sixteen surgeons employing the intrasaccular suture.[3] The number of cases treated was 30; 21 of these cases were treated by intrasaccular occlusion; 5 by intrasaccular repair; 4 by intrasaccular reconstruction.

Among the twenty-one cases of intrasaccular occlusion, there were no deaths from operation, no recurrence, no gangrene, and only one instance of local necrosis. Among the five cases of intrasaccular repair, there were no deaths from operation, no gangrene, no local necrosis, no recurrence. Among the four cases of intrasaccular reconstruction, there were no deaths from operation, no gangrene, or local necrosis, but there were two recurrences (one requiring amputation, the other a secondary intrasaccular occlusion).

These results speak for themselves. Of course, as cases multiply some failures are inevitable, but facts and figures seem to show that by means of intrasaccular suture they will be reduced to a minimum. In conclusion, I would say that I have found the method simple and easy of performance, and I intend to employ it in every case of operable aneurism I may have, outside of the chest, unless there be some positive contraindication.

ANEURISM: OPERATION, RECOVERY.

JAMES R. YOCOM, M.D.
TACOMA, WASH.

Patient.—F. M., aged 29, German by birth, left the U. S. Navy seven years ago and since then has worked as longshoreman and as tapman at the smelter.

History.—He gives a doubtful history of syphilis in 1898. In February, 1905, he was burned on the chest and face (first degree) and the right upper arm (second degree).

On St. Patrick's day, 1900, he had a row with the police in a dance house. He slipped and struck his left knee on the edge of a deep wooden gutter; slept in the police station on the cement floor (drunk), and the next morning his leg (back of the knee and calf), was "swollen as big as his thigh." He went to the hospital; there was no mark or bruise on the leg, but it was swollen from the back of the knee up to the back of the thigh, and remained so (in spite of massage and liniment) for nearly seven weeks. When he left the hospital at that time the general swelling had gone down, except for a "swelling about the size of a hazel nut," in the left popliteal space. It was stated that: "Now and then his leg hurt him a little, but he was apparently well except for the slight swelling."

Some time in the last of January, 1905, he noticed that his leg became a little stiff after sitting still and that the lump was growing more rapidly. It was then the size of a walnut. (Then he was burned, as stated above, and was in the hospital.) In September, 1905, the lump was decidedly bigger and he was in misery all the time—"could count the pulse beats in the swelling." The calf of the leg has always been a little larger since the injury five years ago—but since January, 1905, it has been decidedly larger, and is now much larger than the right, and especially when he walked it had a tired feeling, and he sometimes had to stop and rest.

Examination.—He was a well-built, well-nourished man, in good general physical health. A swelling back of the knee occupied the popliteal space, which bulged backward so as to make a smooth convex surface from side to side, instead of the normal scaphoid depression. The swelling pulsated in all directions synchronously with the pulse, and a well-marked bruit could be heard over it. The left leg below the knee was nearly one inch larger in circumference than the right, and he complained of the full tense feeling of this leg, particularly when he first goes to bed at night.

Operation.—Oct. 30, 1905, with the assistance of Drs. Green and McCreery, I operated on him at the Fanny C. Paddock Memorial Hospital at Tacoma. A tourniquet was placed around the left thigh, tightly enough to control the circulation, but it was thought better to pass a provisional loop around the popliteal artery at its origin; by drawing on this loop the pulsation could be stopped without help from the tourniquet.

I cut directly down on the aneurism sac (pushing the nerve to one side) and having thoroughly exposed it to view on the posterior surface, opened it from top to bottom, allowing some blood and some recent clots to escape. I then removed a considerable quantity of old, hardened fibrinous blood-clot which reinforced the wall of the sac proper, forming a dense, firm lining which was closely adherent to and separated with difficulty from the true wall. The sac, when thoroughly empty, was about as large as a duck egg, and showed very clearly on its deep surface two main openings from one and one-half to two inches apart, respectively, to the proximal and distal portions of the popliteal artery; there were also several other openings into branches. There was no difficulty in constructing an artery from the wall of the sac; no tube was used to secure the proper caliber. A full curved needle and continuous chromic No. 1 catgut suture was used.

After two rows of continuous suture had been placed, the assistant slacked up on the tension loop used to control the hemorrhage and allowed blood to flow through the newly made vessel; it leaked considerably between the stitches at the distal end, showing me where more stitches closely placed were needed. This was done, the circulation was tried again and found satisfactory. Perhaps had this test been made and the weak spots reinforced by other operators their results would have been satisfactory and permanent.

Instead of folding and refolding the superfluous parts of the wall of the sac to reinforce the suture line of the newly made artery, the redundant walls of the sac were sewed together by continuous layer sutures of catgut to secure extensive reinforcing approximation of the endothelial surfaces outside of the original suture line, being careful at the same time to close the openings of the smaller arterial branches passing from the sac. Loosening the control loop, which the assistant had held throughout the operation just tightly enough to prevent hemorrhage into the sac, pulsation was immediately felt, plainly and distinctly in the dorsalis pedis artery. The deeper wound was closed with tension sutures of silkworm gut and the skin by horse hair. The leg and thigh in full extension were enclosed in a voluminous cotton dressing with a snugly placed bandage and a long posterior splint.

Result.—There was an uninterrupted recovery and in three weeks the man walked out of the hospital; his only complaint was a swelling of the leg, which, though much less than before the operation, still persisted and appeared to be due to the varicose condition of some of the veins—due to the original obstruction from pressure of the aneurism.

Remarks.—Eight months after the operation the result of the operation was apparently perfect.

This Matas operation is remarkably simple and efficient—characteristic of the work of a master mind.

---

New and Non-Official Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NON-OFFICIAL REMEDIES." THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

BROMIPIN.

TEN PER CENT. BROMINIZED SESAME OIL, MERCK.

Bromipin is a bromine addition product of sesame oil, containing 10 per cent. of bromine in organic combination.

It is prepared by the action of bromine chloride on sesame oil, in sufficient quantities, theoretically calculated, to produce the required brominization.

It is a yellow, oily liquid, having a purely oleaginous taste, and having a sp. gr. of 0.995 to 0.997.

If to 1 Cc. of bromipin in 10 Cc. of chloroform a few drops of phenolphthalein solution are added, the addition of one drop of half normal potassium hydroxide V. S. should produce a red color (limit of acidity). Estimation of bromine: 1 Gm. of bromipin is boiled with a solution of 2 Gm. of potassium hydroxide in 10 Cc. of alcohol until saponified. The solution is evaporated on a water bath, the residue is charred and the char is repeatedly extracted with small portions of water, and these are passed through a filter. To the filtrate 5 Cc. of nitric acid, 15 Cc. of tenth-normal silver nitrate V. S. and 1 Cc. ferric-ammonium sulphate test solution are added and the excess of silver nitrate is determined with tenth-normal ammonium sulphocyanate V. S. 1 Cc. tenth-normal silver nitrate = 0.007936 Gm. of bromine.

Actions and Uses.—Bromipin acts like the bromides, but as it yields its bromine more slowly it is thought to have less tendency to produce brominism. The combination is not broken up in the stomach, but a portion of the bromine is split off as soon as the oil enters the intestine. The oil with the remaining bromine is easily absorbed, and, similarly to other fats, is largely deposited in the tissues, where it is slowly split up. It is said to be more lasting in its action than the bromides.

Dosage.—4 Cc. (1 fluidram), increased in cases of epilepsy to from 8 to 32 Cc. (2 to 8 fluidrams); in emulsion with peppermint water and syrup, or pure, flavored with oil of peppermint.

Manufactured by E. Merck, Darmstadt. (Merck & Co., New York). German patent No. 96,495.

BROMIPIN—33 1-3 PER CENT.

A 33 1-3 per cent. brominized sesame oil.

This preparation is also offered in capsules containing each 2 Gm., and as tablets of bromipin (bromipin solidum saccaratum) containing 1.2 Gm. of 33 1/3 per cent. brominized sesame oil, corresponding in bromine content to a teaspoonful of bromipin 10 per cent.

Manufactured by E. Merck, Darmstadt. (Merck & Co., New York). U. S. patent No. 774,224; German patent, No. 150,763.

BUTYL-CHLORAL HYDRATE.

TRICHLORBUTYLIDENE GLYCOL. CROTON CHLORAL HYDRATE. CHLORAL BUTYLICUM.

This compound, $CH_3.CHCl.CCl_2.CH(OH)_2 = C_4H_7O_2Cl_3$, is official in the British Pharmacopeia as Butylchloral Hydras.

Actions and Uses.—Its action is similar to that of chloral, except that it is said to be less depressing and more analgetic. It has been especially recommended for facial neuralgia.

Dosage.—0.3 to 1.3 Gm. (5 to 20 grains).

CALCIUM ICHTHYOL.

A derivative of ichthyol in which calcium is substituted for ammonium.

It is a brown, tasteless powder, insoluble in water, and containing 2.5 per cent. of calcium.

Manufactured by the Ichthyol Co., Hamburg (Merck & Co., New York).

CALOMELOL.

COLLOIDAL CALOMEL.

A soluble colloidal form of calomel, containing albuminoids.

According to the patent it is prepared by acting on a solution of sodium chloride in presence of a proteid with mercurous nitrate and precipitating the water soluble colloidal calomel by means of alcohol. The precipitate is washed with alcohol, redissolved in water with the aid of a little alkali, and from this *solution the colloidal calomel is obtained either by evaporation* or by precipitation with alcohol.

It forms a white-gray, odorless and tasteless powder, containing 80 per cent. of mercurous chloride and 20 per cent. of proteids. It is soluble in water, forming an opalescent solution; insoluble in alcohol, ether and benzene. It is precipitated from its aqueous solutions by acids, the precipitate being redissolved by alkalies.

It is incompatible with soluble hydroxides, carbonates, iodides, oxidizing agents, etc.

Actions and Uses.—Its action is the same as that of calomel, but it is claimed to be superior because of its solubility in water, acting more rapidly and efficiently. Calomelol is claimed to be non-irritant and particularly non-toxic. The indications for its use are the same as for calomel.

Dosage.—Internally the same as calomel. Externally it is used as a dusting powder, mixed with an equal quantity of starch or of a mixture of starch and zinc oxide, or in the form of calomelol ointment. It should be guarded from the light.

Manufactured by The Heyden Chemical Works, New York. U. S. patent No. 740,855. U. S. trademark.

CALOMELOL OINTMENT.

An ointment containing 28 per cent. of mercury in the soluble form of calomelol (which see) and 2 per cent. in the insoluble form.

It is prepared by combining 45 parts of calomelol with sufficient lard to make 100 parts.

Actions and Uses.—It is a substitute for mercurial ointment, over which it has the advantage of cleanliness, and it is claimed to be distinctly superior as an inunction in syphilis, etc.

Dosage.—6 Gm. (90 grains) daily for inunction in syphilis.

Manufactured by The Heyden Chemical Works, New York. U. S patent No. 740,855.

CASCARA EVACUANT.

A preparation said to contain a bitterless glucoside, obtained from the bark of *Rhamnus purshiana,* with aromatics.

The bark, which has been stored two years or more, is exhausted with water, the liquid extract concentrated, and the bitter glucosidal substances removed, leaving the bitterless principles which constitute the active ingredients of the preparation.

It is a dark red brown liquid, with an odor and taste suggesting licorice, it being slightly and persistently, but not unpleasantly, *bitter.*

The glucosidal nature may be shown by the following: If precipitated from the aqueous alkaline solution by acids and redissolved in water it does not reduce Fehling's solution, but if redissolved in water, boiled with an acid and neutralized, it reduces that reagent. The glucoside is soluble in water, slightly soluble in alcohol, insoluble in ethyl acetate, chloroform, ether, benzol and benzin. The aqueous solution is colored red by alkalies, the alkaline solution may be partially precipitated by acids. Solution of lead subacetate precipitates the glucoside from its aqueous solution.

Actions and Uses.—It is claimed that this preparation possesses the laxative properties of cascara sagrada without the bitterness which characterizes the ordinary extract. It is recommended for the treatment of chronic constipation, for which cascara sagrada is one of the best medicinal agents.

Dosage.—As a laxative, 0.6 to 1 Cc. (10 to 15 minims) three times a day; as a purgative, 1.3 to 2 Cc. (20 to 30 minims) morning and evening. 4 Cc. (1 fluidram) may be given in obstinate cases.

Prepared by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

CASCARA TONIC LAXATIVE GLOBULES

Each globule is said to contain 0.2 Gm. (30 grains) of the bitter glucosides of *Rhamnus Purshiana* suspended in a bland fixed oil, to which aromatics have been added.

The bark of *Rhamnus Purshiana*, stored not less than two years, is exhausted with water, the liquid evaporated and the extract treated with a solvent which extracts the bitter glucosides, which are mixed with a fixed oil and dispensed in capsules.

The capsules are nearly black in color and contain a fixed oil in which the extract is partly suspended, partly precipitated as a sticky, black extract of an intensely and persistently bitter taste. The odor is fragrant.

The fixed oil may be removed by ether in which the glucosidal bodies are almost insoluble, and the nature of the latter may be tested as follows: Its hydro-alcoholic solution does not reduce Fehling's solution at once, but after boiling the precipitated glucosides with dilute acids and neutralizing, the resulting product does reduce that reagent.

The aqueous solution is colored purplish red by alkalies; from the alkaline solution a yellow substance is precipitated by acids. Solution of lead subacetate precipitates the glucoside from its aqueous solution. The glucosides are partially soluble in water, ethyl acetate, and in 25 per cent. alcohol, entirely soluble in alcohol of from 50 to 80 per cent. by volume, only slightly soluble in chloroform, ether, benzene or petroleum benzin.

Actions and Uses.—The manufacturers claim that it combines the laxative action of cascara with tonic properties of the bitter principle with the advantage of concealment of the disagreeable taste.

Dosage.—One or two globules to be taken before retiring.

Prepared by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

CHINAPHENIN.

PHENETIDIN QUININECARBONIC ACID ESTER.

Chinaphenin, $CO(NH.C_6H_4OC_2H_5)(C_{20}H_{23}N_2O_2) = C_{29}H_{33}N_3O_4$, is the quinine carbonic acid ester of phenetidin.

It is prepared by the action of quinine on p-ethoxyphenyl carbamic acid chloride.

It is a white, odorless and tasteless powder, difficultly soluble in water, but readily soluble in alcohol, ether, chloroform, benzene. Acids dissolve it with the formation of soluble salts.

It gives the thalleioquin reaction for quinine salts, but forms a yellow herapathite.

It is decomposed by acids with the liberation of quinine.

Actions and Uses.—Chinaphenin combines the antiperiodic properties of quinine with the analgesic power of phenacetin, with the advantage of tastelessness and asserted freedom from symptoms of cinchonism produced by the administration of the two remedies in simple mixture. It is recommended in febrile diseases, especially la grippe; in spasmodic conditions, such as whooping-cough; in certain forms of malaria and in neuralgia.

Dosage.—Adult: 0.3 to 0.6 Gm. (5 to 10 grains) ordinarily, or 1.5 to 2 Gm. (22 to 30 grains), given in two doses as an antipyretic in neuralgia and malaria; in whooping-cough, 0.13 to 0.3 Gm. (2 to 5 grains), according to age.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. patent No. 637,839. Vereinigte Chininfabriken. Zimmer & Co., Frankfurt a. M. German patent No. 109,259.

CHLORBUTANOL.

TRICHLOR-TERTIARY-BUTYLALCOHOL. ACETONE-CHLOROFORM.

Chlorbutanol is 1,1,1-trichlor-2-methyl-propan-2-ol, $CCl_3.C(OH)(CH_3).CH_3 = C_4H_7OCl_3$, produced by the reaction of acetone on chloroform.

Made by the action of caustic alkalies on a mixture of chloroform and acetone. It is a white, crystalline, volatile compound having a camphoraceous odor and taste. It is soluble in water (8-1000), in oils, and glycerin; very soluble in alcohol, ether, benzin, glacial acetic acid, chloroform and acetone.

Actions and Uses.—It is said to be absorbed unchanged, but to be decomposed in the body. It is a local anesthetic with an action weaker than that of cocaine, but sufficient to prevent vomiting from gastric irritation. Its antiseptic action is said to be fifteen times as strong as that of boric acid. It acts on the central nervous system similarly to chloral, and although the claim has been made that hypnotic doses are without effect on the circulation and respiration, independent observers have described a fall of blood pressure and interference with respiration in animals, and consider it fully as dangerous as chloral. In man 100 grains caused severe symptoms, but recovery occurred. It is claimed that no habit is induced, but this may be referable to its restricted employment. It is recommended as a mild local anesthetic, in dentistry, etc., as a preservative for hypodermic solutions, for insomnia, vomiting, and for spasmodic conditions. It is also said to be useful as introductory to general anesthesia, lessening excitement and nausea.

Dosage.—The dose is from 0.3 to 1.5 Gm. (5 to 20 grains) dry or in capsules. Hypodermically as a local anesthetic a saturated aqueous solution may be used.

CHLORETONE.

A name applied to chlorbutanol, which see.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

CHLORETONE INHALANT.

Chloretone (chlorbutanol), 1 Gm.; camphor, 2.5 Gm.; menthol, 2.5 Gm.; oil of cinnamon, 0.5 Gm.; refined liquid petroleum, 93.5 Gm.

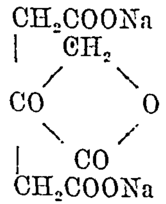
Actions and Uses.—An anodyne, antiseptic, and emollient solution for use by inhalation as a very fine spray or nebula.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

CITARIN.

SODIUM ANHYDROMETHYLENE CITRATE.

Citarin,



$= Na_2C_7H_6O_7$, is the normal sodium salt of anhydromethylene-citric acid.

Anhydromethylene-citric acid is obtained by reacting on citric acid with paraformaldehyde (Schering, German patent 129,255) or with chlormethyl alcohol, CH_2ClOH (German patent 150,949). The sodium salt is obtained by treating the acid with sodium hydroxide solution and precipitating the resulting salt with alcohol (U. S. patent 715,329).

It is a white, granular, somewhat hygroscopic powder, having a faintly saline and acidulous taste, and a slightly acid reaction. It is readily soluble in about 1.5 parts of water, but insoluble in alcohol. Its solutions split off formaldehyde when heated, particularly in the presence of alkalies, and mineral acids separate from its concentrated solutions methylenecitric acid.

Formaldehyde can be demonstrated by means of Jorrisson's reaction, or by sodium nitrite and sulphuric acid, or by silver nitrate and soda solution.

It is incompatible with acids and alkalies and is decomposed by heat.

Actions and Uses.—This is one of the compounds which it is claimed increase the elimination of uric acid by forming very soluble compounds with that substance. It has been recommended for gout and chronic rheumatism.

Dosage.—1 to 2 Gm. (15 to 30 grains), largely diluted with water.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. patent No. 715,239.

SATURDAY, SEPTEMBER 29, 1906.

HYPERSUSCEPTIBILITY AND TRANSMITTED IMMUNITY.

The valuable paper of Rosenau and Anderson on hypersusceptibility, which was presented at the recent session of the American Medical Association in Boston, and of which the authors' abstract appears in this issue, calls fresh attention to a most important "immunity reaction." We are all familiar with the occasional examples of individual and family hypersusceptibility which may be manifested against many drugs and certain infections. This is a natural hypersusceptibility. Since the time of Koch, however, facts concerning a peculiar acquired hypersusceptibility have been gradually accumulating.

The tuberculous individual, for unknown reasons, acquires a delicate susceptibility to an injection of tuberculin which the non-tuberculous does not possess. Experience in the immunization of animals with toxins and bacteria has brought to light other examples in which the immunizing process resulted in heightened susceptibility to the substance injected, rather than immunity. Animals which have endured prolonged immunization with tetanus or diphtheria toxin may suddenly prove intolerant to further immunization even with small doses, and death is not uncommonly the result of this acquired susceptibility. The seemingly paradoxical fact that liberal amounts of antitoxin may be present in the serum of such animals has furnished the subject of immunity with one of its knottiest problems. Behring described the condition as one of "histogenous hypersusceptibility" which manifested itself in spite of the presence of antitoxin in the blood. Wassermann explained it by the assumption that the immunization brings about a heightened "avidity" on the part of the cell receptors for the toxin, which is so great that the toxin combines with the cells rather than with the antitoxin which is present in the blood of the animal. Other examples of a similar character are known.

The hypersusceptibility which forms the subject of the paper by Rosenau and Anderson may or may not be identical in principle with that alluded to above. It is all the more striking in this respect, at least, that it involves an acquired susceptibility to a substance, horse serum, which in itself on first injection appears to be non-toxic. It seems to have been the experience of a number of investigators that animals do not stand prolonged immunization with various albuminous substances, although the latter have little or no toxicity when injected in single large doses. It is probable that the many fatalities which occur in the attempt to produce immune cytotoxic serums depend on a similar principle. Arthus, in 1903 (*Société de Biologie*) published observations showing the toxicity of repeated injections of horse serum into the rabbit. Pirquet and Schick had shown also the toxicity of a second injection of antitoxin or horse serum in relation to the "serum disease." It is learned from a recent publication by Otto[1] that Theobald Smith had noted the frequent toxicity of a second injection of horse serum as early as 1902, and it was through the suggestion of Smith that Otto undertook a study of the subject. That Smith's attention had been called to the phenomenon was also brought out in the discussion which followed the reading of the paper. This fact would seem to detract nothing from the originality of the work of Rosenau and Anderson, however, since they apparently encountered the phenomenon independently.

The results obtained by Rosenau and Anderson coincide in all essential respects with those of Otto. A study of the details of their experiments[2] indicates the thoroughness with which the work was conducted, and their conclusions are based on a very extensive material.

The phenomenon has a direct and important bearing on the serum disease of Pirquet and Schick, and throws probable light on the disturbing results which occasionally (rarely) follow the administration of antitoxin in man. They prove conclusively, as does Otto, that the untoward effects which may be caused by an antitoxic serum are absolutely independent of the antitoxin which the serum contains.

It is probable that a satisfactory explanation of the phenomenon has not yet been reached. That the hypersusceptibility is "histogenous" was demonstrated by Rosenau and Anderson; it is not a property which resides in the serum of the animals. The explanation offered by Vaughan in this discussion is interesting, but is difficult of proof.

The work is important not only because of its bearing on serum intoxication, but also because of its relation to the general subject of hypersusceptibility to infectious diseases. It is probable that the phenomenon, which seems destined to be known as the Theobald Smith phenomenon, in pursuance of the precedent set by Otto, will prove to be another instance in which a problem of primary theoretical interest may yield results of great practical value.

Other important work from the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service is found in the last bulletin, just issued.[3] In this bulletin Anderson confirms the work of some previous observers (Wernicke and others) concerning the ability of the female guinea-pig to transmit an original immunity to diphtheria to her offspring. In the experiments conducted by Anderson, the surprising observation was made that a guinea-pig which had been treated with a mixture of diphtheria toxin and antitoxin transmitted distinct immunity to her offspring, whereas animals which had been treated with the toxin alone transmitted no such immunity. This seems not to have been explained satisfactorily as yet. The transmitted immunity appeared in each of four successive litters, but was not passed into the third generation.

---

[1] Das Theobald Smithsche Phänomenon der Serum Ueberempfindlichkeit, v. Leuthold Gedenkschrift, vol. 1.

[2] Bulletin 29 of the Hygienic Laboratory, U. S. P. H. and M. H. Service.

Emphasis is placed on the importance of this transmitted immunity, as well as on the transmitted hypersusceptibility to serum (Rosenau and Anderson) in the testing of toxins and antitoxins by manufacturers of serums. The value of an antitoxin may be greatly overestimated, on the one hand, by testing it on a guinea-pig which has inherited an immunity to diphtheria from its mother; on the other hand, the results of the tests for bacterial or toxic impurities may be equally erroneous if they are performed on guinea-pigs which have inherited a fatal susceptibility to serum from a "used" mother.

It is worthy of comment that the government, in maintaining laboratories for practical purposes, has found it necessary to place these laboratories under the direction of men who have the investigative spirit, and to encourage this spirit by providing facilities for pure research. Experience has taught well the lesson that the practical when thoroughly divorced from the theoretical ceases to be practical.

A NATIONAL DEPARTMENT OF HEALTH.

The government is designed for the welfare of the people, and in a government like ours, of the whole people, one of the first considerations in the people's welfare is their health; material resources are secondary. Without an able-bodied race, no country can prosper, and it is the favoring health conditions of the temperate zones that have made the races inhabiting them the rulers of the world. With the artificial conditions of civilization, however, the problem of the public health comes more and more to the front, and the old *laissez faire* methods show their deficiencies. More than one country at the present time is seeking methods and means to check the degenerative tendencies that threaten them, and the question whether our civilization is to last seems largely to depend on the success of these efforts.

The paper of Professor Norton, published in this issue of The Journal, puts forth the economic side of the question as fully and fairly as any publication of its compass that has lately appeared. Coming from a nonmedical man, it is an encouraging sign. Professor Norton shows how great a waste exists at the present time from preventable deaths, sickness and conditions of physical and mental inefficiency, due largely to the lack of a wise general governmental supervision. We have our pure food laws and our quarantine laws which go a certain way toward checking these evils, but they are, after all, only a beginning of what is needful. We have a great deal of government in regard to health matters, but it is local, unsystematized and often conflicting in different sections of the country and is distributed also, so far as it relates to national affairs, under different departments of the government, thus preventing the best results. The plea for a national department of health could be, to a certain extent, met by the consolidation under a single head of already existing bureaus without a great additional expense, but completeness and full efficiency would demand more than this.

The plan laid out by Professor Norton covers a much broader field, and, while it may not be absolutely realizable at once, the consolidation of the existing bureaus would be a great step in advance and could be enlarged on as wisdom and experience would dictate. The work done on less than a million and a half by the Public Health and Marine-Hospital Service is itself an indication of what a wise expenditure of only a moderate amount of public funds can accomplish. The protection of our southern coast from yellow fever, which it has practically accomplished, is worth annually many times the whole cost of that department, but this is a local service which principally benefits a section and not the whole country. An intelligent direction of health matters, including far more than that bureau at present has under its control, would be of still more widespread and general advantage. A considerable amount of the work done under the Agricultural Department, which is of the utmost value, including, for example, the admirable work of Dr. Wiley and that now assigned it under the pure food law, should properly be consolidated with the sanitary functions of other departments. Then a cabinet officer with expert knowledge of health matters could administer all these and other new departments to much better advantage than under the present system.

The value of an intelligent health administration to the power of the nation in war was never better exemplified than in the recent Russo-Japanese war, and the victories of peace are likewise dependent on the preservation of the national health efficiency. It is not only the man behind the gun, but the man behind everything else tending to national prosperity that counts, and the sound mind in the sound body is a real element in national as well as individual prosperity. How far criminality is concerned with disease is an important social question, and we know what the tendencies of certain sociological thinkers are on this matter. Leaving all extreme ideas aside, there is no question but that a healthy people, other things being equal, is more amenable to moral improvement than one in whom disease conditions prevail. A department of health, exercising a wise supervision over all subjects of national bodily welfare, could thus indirectly, at least, be a valuable adjunct to good government.

---

[3] Maternal Transmission of Immunity to Diphtheria Toxin and Hypersusceptibility to Horse Serum in the Same Individual. Bulletin 30, Hygienic Laboratory, U. S. P. H. and M. H. Service.

The importance of health matters to any civilized country is greatly enlarged at the present time by the vastly increased facilities for communication, and sanitary questions of international importance are constantly arising. The importance of the office is still further magnified and its necessity as a special department with a cabinet officer at its head is strongly accented by the international complications arising involving sanitary questions of the highest importance. Moreover, as this country becomes more and more a world power the scope of such a department is greatly widened. For these, in addition to the economic reasons so well stated by Professor Norton, the advisability of such a department is all the more obvious. We can hardly add to the economic argument so well stated in the article, excepting by emphasizing the important truth that what is right is also profitable. Righteousness exalteth a nation, and governmental attention to the physical salvation of the people is, if anything else is, in the line of practical and political righteousness.

THE AMERICAN MEDICAL DIRECTORY—A PRELIMINARY STATEMENT.

One of the apparently new lines of work inaugurated by the American Medical Association is the compilation and publication of a Medical Directory, based on material drawn from the official records of the various state licensing boards. We say "apparently" advisedly, for this feature of the Association's activity is only an extension of a work in which it has always been interested, namely, the elevation of the personnel of the profession and the safeguarding of the public health through the elimination of those who, either on account of lack of proper training, or owing to deficient mental or moral endowment, are unfit to practice medicine. Almost from the time of its organization the Association has striven for the accomplishment of these ends.[1] It has repeatedly declared in favor of the state laws regulating the practice of medicine and establishing examining and licensing boards. It has always favored the enforcement of these laws.

The practice of medicine in a civilized community is something more than the pursuit of a private business or calling. As Huxley showed, the physician bears a peculiar relation to the state, which justifies the civil government in demanding a certain amount of preparation and a demonstration of fitness from each candidate before allowing him to practice medicine. This principle, comparatively new in Huxley's day, is now universally recognized. Each state and territory now has a law establishing and maintaining a board for this purpose. No one is allowed to assume responsibility for the lives and health of the public, unless he is first granted a license by a board of the state in which he desires to practice. This law is of benefit to the profession by keeping the unfit out of its ranks; it is of much greater benefit to the public by protecting it against the untrained and the unprincipled.

The regulation and protection of public health is one of the police powers reserved by the constitution to the state. Each board, therefore, has jurisdiction only over the territory of the state which created it. Any coöperation between state boards is, necessarily, purely voluntary. It is to the interest of the public as well as of the profession that there be as much uniformity as possible in the standards of these boards and that each be cognizant of the work of the others. Our state laws regulating medical practice are, to-day, an absolute necessity. It will also be conceded that state licensing boards have wrought a marked improvement in the medical profession and have also been of great benefit to the public. The need of to-day, however, is closer relation, more coöperation and greater uniformity among the state boards. Such coöperation must be voluntary and can only be brought about by demonstrating the value which each board can be to the others. Since the work of the licensing body is the acceptance of the fit and the rejection of the unfit, the greatest service which any board can render is to share with the other boards the knowledge and experience it has gained, regarding those whom it has accepted or rejected. Some attempts have been made along this line. Of 70 licensing bodies, 22 have published, at different times, a list of those licensed to practice in their state. Some of these reports are excellent and are a credit to the boards issuing them; but their circulation usually has been confined to the states which issued them and to members of other boards to whom they have been sent. In some cases, they have been buried in the annual reports of the board. With a few exceptions, they have been published at long intervals and the various editions have not been accessible to the public nor, in many cases, to the profession. With limited means and large responsibilities, the average board is not able to expend much money in revising or printing its records.

Now, a law is of no value unless it can be enforced. It can not be enforced unless it is possible to detect violations of it. There must, therefore, be some ready means of ascertaining whether or not a given physician has complied with the law. In some states, it is practically impossible to determine this point; in many more, it is difficult and expensive. In most states, in order to ascertain the legal standing of a physician, it is necessary to write to, or to call on, the secretary of the state board. In a number of states, even this would not suffice, since the records are kept by the various county clerks. In one state, there are 67 counties, each with its separate register of licensed physicians. In one of these counties, there are over 7,000 names on the records; in another county there are over 3,000. These names are entered in the order in which the applications were made, without alphabetical arrangement or index. To determine positively, whether or not a physician is licensed to practice medicine in this state might require the examination of every name on the 67 county records. Such an amount of work makes the enforcement of the law impossible. In another state, where, previous to 1890, a similar system of registration was in force, it would be necessary to examine the records of the state board, which only go back to 1890, and then to examine the records of each of the 22 counties in the state. Who is responsible for the enforcement of the registration law in states which depend on county officials for their records of medical practitioners? The county clerk is supposed to be, but his sole interest is the collection of a fee for each license which he registers. Since it can not be proved that a given individual has violated the law, it is manifestly impossible to convict him.

---

[1] Dr. Bartles introduced the following resolution: "Resolved, That the union of the business of teaching and licensing in the same hands is wrong in principle and liable to great abuse in practice. Instead of conferring the right to license on medical colleges, and state and county medical societies, it should be restricted to one board in each state, composed in fair proportion of representatives from its medical colleges and the profession at large, and the pay for whose services as examiners should in no degree depend on the number licensed by them."—Proceedings A. M. A., May 5, 1846, vol. i, p. 19.

The weak point in our system of medical legislation is that each state is a separate unit, keeping its own records, issuing its own licenses and publishing its own roster, if it does so, without any reference to other states. It has been recognized that immense good would result if all the information collected by the various state boards could be properly arranged and placed at the disposal of all of the boards, to be used for the benefit of the profession and the public. But there has been no systematic effort made to inaugurate such a work. It is evident that it is fundamental and that it must eventually be done by some one. It is obviously unreasonable to expect any one state board to assume the labor and expense of this work. It is equally out of the question to expect the general government to undertake it. It is too expensive and unremunerative for private enterprise. The medical profession itself, therefore, is the only agent left to undertake it. It has hitherto been impossible for the profession to undertake this task, owing to the lack of funds and incomplete organization. These two obstacles having been removed by the work of the past few years, it was decided at the Portland session that the time had come for the organized profession to take up this needed reform.

Accordingly, in September, 1905, correspondence was entered into with the secretary of each licensing board; the objects of the Association were clearly set forth; the advantages which would accrue to each board were explained and the coöperation of each board was requested. Without exception, this was given cheerfully and willingly. Complete copies of the official records of the board, containing the names of all physicians licensed to practice medicine, were obtained. These names were properly arranged and indexed. In states having a county system of registration, it was necessary to secure copies of the records from each county clerk. This work showed clearly the great need of a reform such as the Association had undertaken. Almost without exception, those records which were kept by county clerks or by lay officials were found to be in a deplorable condition of inaccuracy and incompleteness. In some cases, obtaining the desired information entailed much labor and expense and required much patience. Eventually, however, complete copies of the records of all licensing or registering bodies were secured. At the same time, arrangements were made by which these records are kept corrected up to date, through reports furnished by the secretary of each board, following examinations.

Arrangements are also being made by which each secretary will send to this department information regarding physicians whose licenses have been revoked or who have attempted to deceive the board by means of false statements or by forged or altered diplomas or credentials. This matter will be distributed to each board by the Association. In this way, each board will profit by the experiences of all.

Turning now to the medical colleges, we find a condition similar to that which obtains among registering boards. There has been, heretofore, no central bureau for collecting and preserving information regarding medical graduates. When a college became extinct, its records were often irrevocably lost. There has been no way of verifying statements regarding graduates, and consequently, in many cases, both the public and the profession have been imposed on. Accordingly, arrangements have been made with the existing medical colleges by which the names of all graduates for the past five years have been obtained, thus supplementing a list of previous graduates already in the hands of the Association. Hereafter, the name of each new graduate, with biographical information regarding him, will be obtained by the Association at the time he receives his degree. This will thereafter be preserved in permanent form. Colleges that request it will be provided, at any time, with information in the possession of the Association.

It will thus be seen that the Association, in the last year, has compiled a complete list of legally qualified physicians and a fairly complete list of medical graduates. This material is now stored in the vaults of the Association. Such a work has never before been undertaken. This department of the Association is now in a position to supply information regarding practicing physicians either to the state boards or others. The immediate response of every one of the secretaries of the state boards shows that they appreciate the need of such a work. The Association has established what is practically a central bureau of information regarding the medical profession of the entire country. It is now possible for the secretary of every state board, as well as every state health officer, to avail himself of any information in the possession of any of the 70 boards. The Association now has, for the first time in its history, a legal basis for the compilation and publication of personal and biographical matter relating to the profession.

It will thus be seen that the Directory is only a secondary and subsidiary matter, which is subordinate to a much greater work which the Association has undertaken. The American Medical Directory is a compilation of a part of the facts regarding each physician as they now appear on the records of the Association. The consideration of medical directories in general, as well as of the points of difference between the American Medical Directory and other directories, will be reserved for future discussion.

COMMERCIALISM AND DRUG ADULTERATION.

The New York City Board of Health has recently shown by careful investigation that a considerable portion of the drugs which have been sold in the past year and even those which enter into the composition of physicians' prescriptions are either below grade in quality or are absolute substitutions of cheaper for more expensive materials in order to secure more profit for the dealer. It is, of course, an extremely sad state of affairs when human life and illness and suffering are trifled with in this manner for the paltry difference in profits that may thus accrue. The discovery has given rise to no little pessimistic discussion in the newspapers, as if this were the first time that any such unfortunate lapse from rectitude had been noted and as if our generation were by that so much worse than any of its predecessors. The adulteration of drugs, however, has nearly always been a source of difficulty in the practice of medicine, and this is only another example of a very human tendency.

The reason for the present manifestation of human fallibility is not far to seek. In recent years druggists have come to be tradesmen much more than they used to be. The apothecaries were a guild in the olden times and are supposed to preserve a considerable degree of professional spirit. Unfortunately, the custom of selling various proprietary medicines at cut rates in order to attract custom has led more and more to the invasion of a thoroughly commercial spirit into the drug business. Not satisfied with cutting rates on "patent medicines," some druggists have advertised cut rates also in the filling of prescriptions. As a rule, this could be accomplished profitably only by purchasing drugs from the wholesaler at prices cheaper than they could be furnished if they were of the proper standard of purity, or else by substituting cheaper drugs for those named in many prescriptions. The wholesaler is to blame as much, if not more, than the retail druggist, and it is to be hoped that the punishment for the offences discovered will be meted out to the real culprits in the case.

It would be eminently desirable, however, that the modern druggist should make much more of a specialty of prescription filling than of the many side issues which now occupy so much space and attract so much attention in the apothecary shops. Physicians can do much to bring about an improvement in this matter by encouraging patients to take prescriptions to such pharmacists as properly maintain their professional dignity as apothecaries and do not allow the commercial spirit to obtrude itself unreasonably in their business.

STATE SOCIETY AUXILIARY COMMITTEE. as one

At the last meeting of the Ohio State Medica to the ciation the following by-law was adopted: "ly over annual meeting for the election of officers each co opera- nent society shall appoint one of its members as a member of the Auxiliary Committee on Public Policy and Legislation, and the secretary shall send his name and address at once to the secretary of the State Medical Association. The Committee on Public Policy and Legislation of the State Medical Association shall formulate the duties of this Auxiliary Committee and supply each member with a printed copy." It is the intention to have this committee look after the interests of the public and of the medical profession by assisting in the suppression of the "patent-medicine" evil, prosecuting fraudulent and illegal practitioners by inaugurating a system of registration, abolishing medicopolitical partisanship from public office, and assisting the proper public authorities in the suppression of criminal abortion. The work of this committee is an important one, and by having its members distributed over all parts of the state the results of the work done in this direction by the state association will become more effective and far reaching than ever before. Other state societies may well follow in the footsteps of the Ohio association by providing for the appointment of similar committees. It is certainly a step in the right direction.

A MODERN SUPERSTITION.

It is usually supposed that nowadays education has practically done away with superstition, and that whatever manifestations of it are left are to be found only among the ignorant and almost exclusively among the foreign immigrants into this country who have not had the opportunities that have been provided here. The recent automobile race on Long Island, however, almost provided another striking example of the influence of superstition even on educated people. There were to have been fifteen contestants, but fortunately the number was reduced to twelve before the race actually took place. Last year, with more contestants in it, though the different machines were numbered in rotation, the number thirteen was not given out, because it was understood that the drivers objected to riding with so dread a talisman on their cars. They are perfectly willing to risk their lives making records of over sixty miles an hour on an ordinary road, but they are not willing to take the awful added danger that would be incurred by identifying themselves with the number thirteen. It is well known now that most of the passenger steamers, at least those which leave the eastern ports of the United States, do not have state-rooms numbered thirteen because of the objection which many passengers have to traveling in such a room. Many of the hotels that have been built recently have eliminated the number thirteen from their series of rooms for a similar reason. Is it any wonder that with this senseless superstition still rampant, people should continue to think that various peculiar methods of treatment and even nonsensical remedies will relieve them of their pains and ills? What is needed, evidently, is not education in general, but specific training in a state of mind and a development of character that will prevent the domination of such foolish remains of the ignorance of former generations.

NEO-VITALISM.

A considerable portion of the recent opening address[1] of Professor Gotch before the Section on Physiology of the British Association for the Advancement of Science was given to an attack on "neo-vitalism." The principal point made against it was the objection to the admission that physico-chemical explanations must necessarily be insufficient to explain the vital phenomena, and the claim that such admission obstructs physiologic progress. This seems to us equivalent to a confession of weakness and, as it were, an inference that human knowledge is exhaustible or must be assumed so to be in order to encourage the workers. Why should the admission of the fact that there will always be something ahead of us to be explained be a discouragement to the physiologist any more than it is to the astronomer to recognize the fact that he can not look forward to the establishment of the limits of the universe or of infinite space? Has the work of those investigators who have admitted their limitations—men like Pasteur and Faraday, for example, not to mention a host of other workers—been any less fruitful in chemical and bio-chemical research than it would have been but for such recognition? It seems to us doubtful. It would be more modest in physiologists who oppose neo-vitalism so strenuously to profess a little agnosticism in the matter if they are unable to accept the unwelcome element of "mysticism" which they seem to think the doctrine involves. It would also be more scientific, it seems to us, to use less of the argument of expediency against the use of the term. It may be an assumption to say that life is always going to be unexplainable, and there are certain objections to the use of the term vital force which, we think, would be more properly made by the so-called mystics than by their opponents. It is, however, equally an assumption to claim that it will be thus explainable and is also lacking in proof.

---

[1] Nature, Aug. 23, 1906.

Medical News

CONNECTICUT.

New Hospital for Waterbury.—It is announced that $31,006 has been raised for the erection of a Roman Catholic hospital in Waterbury and that the site for the institution has been purchased.

Communicable Diseases.—During August 4 cases of smallpox were reported from two towns; 45 cases of measles from 20 towns; 35 cases of scarlet fever from 22 towns; 2 cases of cerebrospinal fever from one town; 127 cases of diphtheria from 2 towns; 50 or more cases of whooping-cough in 19 towns; 213 cases of typhoid fever in 36 towns, and 37 cases of consumption in 21 towns.

August Deaths.—During August, 1,639 deaths were reported in the state, equivalent to an annual death rate of 10.5 per 1,000. The deaths from infectious diseases numbered 231, or 14.1 per cent. of the total mortality. The principal death causes were: Diarrheal diseases, 337; diseases of the nervous system, 156; consumption, 123; accidents and violence, 110; heart disease, 105; pneumonia, 44; whooping-cough, 39; typhoid fever, 30; diphtheria, 16; measles, 7; scarlet fever, 6; malarial fever, 5, and erysipelas and cerebrospinal fever, each 2.

DISTRICT OF COLUMBIA.

Physicians for the Poor.—The secretary of the district board of charities has recommended that an allotment of $8.030 be made for hiring 22 physicians, at the rate of $1 per day, and that $2,370 be allotted for medicines, nursing and other incidental expenses, for the next fiscal year, beginning July, 1907.

Must Not Drive Fast.—Dr. Milton H. Prosperi, Washington, brought before the district branch of the police court, charged with fast driving, claimed in extenuation that when a physician is making an emergency call he should be allowed to drive faster than the police regulations allow. He was informed that he must observe the law against driving at an excessive speed and was fined $20, which was paid promptly.

Typhoid Fever.—Washington is suffering from an epidemic of typhoid fever, which is remarkable, as it has come immediately on the completion of a three-million-dollar filter plant, whose purpose is to render the water supply pure and sanitary. Dr. Lloyd McGruder believes that the infection is due to a contaminated milk supply, but Dr. William C. Woodward, district health officer, takes issue with Dr. McGruder, and states that every plant from which milk is shipped into the district is systematically inspected by officers of the health department and that in the absence of a laboratory no bacteriologic examination can be made of the milk supply.

Hospital News.—Work is being pushed for the early construction of the Walter Reed U. S. A. General Hospital. The building, which is to cost $200,000, will be constructed of red brick, will be 193 feet long by 25 feet wide, and will be about 125 feet from the ground to the top of the central dome.——Potomac Hospital, which was organized in April last and opened to the public by the colored physicians of the city, for giving free medical treatment to the worthy poor, without regard for race, creed or sex, has proven to be too small for the needs of its applicants, and it is now the hope of the directors to equip and maintain a larger general hospital. More than 1,200 patients have been treated in the hospital up to this time.

GEORGIA.

Hospital Notes.—The city council of Columbus has advertised for bids for the removal of the city hospital from its present site to a more desirable location, and it is probable that an entirely new hospital will be erected with a nurses' training school in connection.——The Atlanta School of Medicine announces the opening of its own hospital, at the corner of Bartow and Cain streets, on October 1. Two wards, with accommodation for 16 patients, have been built during the summer.

College Notes.—The Atlanta School of Medicine opened for enrollment, September 15, and lectures will begin September 26. It has been decided by the faculty that all courses shall be in separate calendar years and the length of the term has been increased from six to seven months. The new building is practically completed and ready for use.——The new building of the Atlanta College of Physicians and Surgeons, erected at a cost of $75,000, will be ready for occupancy about October 1.——The Carnegie donation will be used in fitting up the old Southern College building, which is to be known in the future as the Carnegie Pathologic Institute.

Personal.—Dr. Marion M. Hull has been elected professor of materia medica and therapeutics at the Atlanta School of Medicine, vice Dr. Charles D. Hurt, deceased.——Dr. William S. Elkin has been elected professor of gynecology and obstetrics in the Atlanta College of Physicians and Surgeons, vice Dr. Hunter P. Cooper, deceased.——Dr. Frank M. Ridley, La Grange, has been appointed chief surgeon of the West Point Route, to succeed the late Dr. Hunter P. Cooper.——Dr. Karl H. Hall, Atlanta, has been appointed assistant surgeon, with the rank of first lieutenant, in the Governor's Light Artillery, which is officially known as the Second Field Battery, N.G.,Ga.

ILLINOIS.

Diphtheria.—Kewanee reports a number of cases of diphtheria with two deaths, and many cases of so-called "sore throat."

Itinerant Vendors.—The State Board of Health has officially warned all municipalities to refrain from issuing licenses to itinerant vendors of drugs, who do not hold licenses issued by the board, according to the provision of the statutes.

Personal.—Dr. Charles E. Crawford, Rockford, has been reelected physician of Winnebago County.——Dr. A. D. Winsor has been appointed resident physician of the Maplewood Sanatorium, Jacksonville, vice Dr. Albert H. Dollear, resigned.

Treatment for Consumptives.—The Ottawa tent colony has decided to build a new infirmary 150 feet long by 20 feet wide. ——In the quarterly bulletin of the State Board of Charities the exceptionally beneficial results of the tent colonies at the various state insane hospitals for consumptive patients are given in detail. The tent colony at the Illinois Hospital for the Incurable Insane, Bartonville, shows a per capita cost of only $50 per year.

Chicago.

Cocain Users Fined.—Two negroes charged with using cocain were each fined $10 and costs September 20. Four other men arrested at the same time and place were discharged.

Addition to Hospital.—The Washington Park Hospital Association have the plans prepared for a three-story addition to the institution, to be erected on a lot 50 feet by 150 feet adjoining the hospital.

Trust Deed Given.—The Post Graduate Medical School, through its president, Dr. W. Franklin Coleman, has given a trust deed on its buildings and grounds to secure a loan of $24,000 for five years at 5½ per cent.

Maternity Hospital Planned.—The free maternity department of the American Daughters of the Revolution has made plans for a maternity hospital for the North Side, to be located near Lincoln Park, and to have accommodations for about 15 patients.

Personal.—Dr. and Mrs. Henry P. Newman leave October 1 for San Diego, Cal., for the winter.——Dr. and Mrs. Frederick Tice have returned from abroad.——Dr. William Ewart, London, who has been visiting Chicago, has started for Boston on his way home.

Increase in Typhoid Fever.—The health department has noticed a serious increase in typhoid fever, due, it is believed, to milk, contaminated by polluted water used in washing the cans and other receptacles. The department has closed one infected milk depot and has excluded the milk from two dairy farms, pending examination.

Deaths of the Week.—During the week ended September 22, 582 deaths were reported, equivalent to an annual death rate of 14.81 per 1,000. During the corresponding week of 1905 512 deaths were reported. Acute intestinal diseases caused 122 deaths; consumption, 78; Bright's disease, 44; violence, including suicide, 39; heart disease, 36; pneumonia, 35, and cancer, 25.

Physicians Play Golf.—At the annual tournament of the Chicago Physicians' Golf Association Dr. Charles W. Heywood, Riverside, defeated Dr. William E. Code for the championship; in the second flight finals Dr. William H. Wilder was victorious; Dr. J. C. Hollister won the third flight honors, and Dr. William A. Pusey the honors in the fifth set. At the annual election Dr. John Ridlon was chosen president.

INDIANA.

Urges Detention Hospital.—Dr. Everett E. Hodgin, police surgeon of Indianapolis, urges the city to take steps toward the establishment of a detention hospital for the care of insane patients, as at present there are few facilities for the care of the mentally deranged.

Hospital Opens.—The new hospital of the State College of Physicians and Surgeons, Indianapolis, affiliated with the State University of Indiana, was opened September 15, when 15 patients were removed from Camp Benjamin Harrison to the institution. At the formal opening the attorney-general, the mayor and the president of the university were among those who made addresses.

Births and Deaths of the Year.—The report of the births and deaths in the state in 1905, recently published by the State Board of Health, show that 44,114 births occurred, or 16.65 per 1,000. The largest number of births occurred during July and the smallest number in December. Plural births numbered 184. During the year 36,502 deaths occurred, equivalent to an annual death rate of 13.78 per 1,000. Of the deaths, 19,064 were males and 17,438 were females; 35,096 were white and 1,406 were colored. An interesting feature of the report is that 385 of the decedents were more than 90 years of age.

Typhoid Fever.—Dr. F. Sheldon Hunter, Bedford, secretary of the Lawrence County board of health, has investigated the typhoid-fever situation in Mitchell. He obtained samples from the three public wells, each of which was found to contain typhoid germs. It was reported that Mitchell had 74 cases of typhoid fever, but Dr. Hunter says that only 21 cases have been reported to him.——Reports of a typhoid-fever epidemic near Van Buren have been greatly overdrawn, according to the county health officer, who says that only 3 cases have been reported. Seven cases of fever reported to him a few days before were not typhoid, but malaria.

August Diseases and Deaths.—There was a lower mortality and less sickness in August, 1906, than in the corresponding month of 1905, according to the report of the State Board of Health. Diarrheal diseases were most prevalent. The order of prevalence was as follows: Diarrhea, cholera morbus, typhoid fever, cholera infantum, rheumatism, tonsillitis, dysentery, intermittent and remittent fever, bronchitis, inflammation of the bowels, scarlet fever, "typho-malarial" fever, influenza, diphtheria, pleurisy, pneumonia, whooping-cough, erysipelas, cerebrospinal meningitis, measles, puerperal fever and smallpox. During the month 3,000 deaths were reported, as compared with 3,073 in August, 1905, indicating respectively annual death rates per 1,000 of 13.3 and 13.6. Of the total deaths, 641, or 22.6 per cent., were of infants under one year and 691 of persons over 65 years. Tuberculosis caused 351 deaths. There were 32 fewer deaths from typhoid fever than in August, 1905. Smallpox was prevalent in mild form in four counties, 46 cases being reported. Violence caused 192 deaths, 7 of which were homicides and 22 suicides; of the latter, 6 were from gunshot wounds and 12 from poisoning. Of the accidental deaths, 46 were caused by railway and trolley car accidents, 25 by drowning, 9 by lightning and electricity, 29 by falls and crushing injuries, 9 by burns and scalds and 5 by sunstroke.

IOWA.

Typhoid Fever.—An epidemic of typhoid fever is reported at Storm Lake.——The health officers of Fort Dodge and Ames sound emphatic notes of warning to the residents of these cities regarding typhoid fever, warning them to have their drinking water analyzed, and advising as a routine measure that all drinking water be boiled.

Personal.—Dr. William B. La Force, Ottumwa, has been elected professor of gynecology and abdominal surgery in the Keokuk Medical College, College of Physicians and Surgeons, and has moved to Keokuk.——Dr. Thomas Farquhar, Early, has moved to Spokane, Wash.——Dr. Harold Bailey, Waterloo, has returned after six months in the London hospitals.——Dr. and Mrs. Albert H. Blocklinger, Dubuque, have returned after two years in Europe.

KANSAS.

Physicians Use Automobiles.—Out of the 82 licenses issued for automobiles in Topeka up to September 21, 14 were issued to physicians.

Typhoid Fever at Fort Riley.—It is reported that typhoid fever is prevalent at Fort Riley, and that as the chief medical officer of the camp deems its presence a menace to the health of other organizations, Company H, Thirtieth United States Infantry, in which 4 cases have occurred, has left for Fort Reno, Okla.

To Test River Water.—The secretary of the State Board of Health has signed contracts with the officers of the United States Geological Survey for an examination of the Kansas streams, looking after the solution of the problems of water supply, pollution and sanitation. The government will spend $1,500 and the state an equal amount in making this survey.

College Opens.—The Medical Department of Washburn University, Topeka, opened for the year September 4. Five faculty changes are announced: Dr. John B. Town has been appointed lecturer on embryology; Dr. F. J. Mahon Ernest, instructor in pathology; Dr. Charles B. Van Horn, lecturer on anatomy; Dr. Robert B. Stewart, instructor in clinical medicine, and Dr. Elizabeth Ernest, superintendent of the dispensary.

To Check Consumption.—Dr. S. Jay Crumbine, Topeka, secretary of the State Board of Health, has prepared for general distribution, a pamphlet on the subject of tuberculosis, whose object is to stop the spread of the disease, and warn the people of the dangers arising from it. The pamphlet contains these rules to be followed by state and county officers and employés in the state:

All persons in state and county employ are positively forbidden to spit on the floors.

Rooms, hallways, corridors and lavatories shall be freely aired and effectually cleaned at least once a day, and not during working hours.

Spittoons shall receive a daily cleansing with very hot water, and when placed ready for use must contain a small quantity of water.

Dust must be removed as completely as possible by means of dampened cloths or mops. It should never be needlessly stirred up by a broom or duster, as this practice only spreads the dust and germs.

Floors of tiling, brick or stone must be frequently scoured with soap and water

The senior clerks in charge of workrooms will take measures to secure during working hours the admission of as much fresh air and sunshine as the conditions will permit.

The use of individual drinking glasses is recommended.

Persons in state employ who suffer from pulmonary tuberculosis should be separated, when possible, from others while at work.

Home advice for consumptives:

Sleep alone.

Use no hangings, upholstered furniture or useless floor coverings in your sleeping room.

Whitewashed or painted walls are preferable to those covered with wall paper.

Expose the bedroom freely to the outside air when not occupied, and sleep with the windows open. Spend as much time as possible in the open air, and use the bedroom only at night.

Do not be afraid of cold weather as long as the body is protected, and be especially careful to keep the feet dry.

Keep the body warmly clad and guard against sudden changes in the weather.

Take plenty of nourishing food. Consumptives often need more nutriment than they are inclined to take. Milk, eggs and fatty foods are especially valuable, when they can be assimilated.

There is no known medicine that can cure consumption. Medicines for the relief of cough and other symptoms of the disease should be taken only on the advice of a physician.

MARYLAND.

Typhoid Fever.—Burkettville, six miles south of Middletown, with a population of less than 800, reports 16 cases of typhoid fever, with one death.

English Surgeon in Annapolis.—Staff Surgeon Alexander Gaskill, Royal Navy, who is in America studying naval hospital methods, visited the U. S. Naval Academy, Annapolis, September 20, and inspected the government hospital in process of construction.

Physician Injured.—Dr. Claiborne H. Mannar, Rockville, was seriously injured in a runaway accident near Halpine, August 23. He was kicked by his horse, breaking his jaw and causing severe cuts and contusions of the face. He was taken to a hospital in Washington and is reported to be improving.

Baltimore.

Typhoid Fever.—During the week ended September 15, 63 cases of typhoid fever were reported, and during the week ended September 22, 51 cases.

College Opens.—The Baltimore Medical College opened for its 1906-07 session September 21 with an address by Dr. David Street on "The History of Medicine."

Personal.—Dr. Thomas Shearer is in London.——Dr. William Green has returned from a prolonged trip to northern health resorts.——Drs. Randolph Winslow and J. Mason Hundley returned from Europe September 16.——Dr. Harry Adler has been unanimously elected president of the Hebrew Hospital and Asylum.——Dr. Roland B. Whitridge sailed from Genoa on his return from Europe, September 20.——Dr. Howard A. Kelly sailed from New York for Europe, September 12.

Hospital News.—An appropriation for $25,000 has been allowed for the erection of a hospital for infectious diseases, adjoining Bay View.——Johns Hopkins Hospital is considering the erection of a new building for the children's ward, to be three stories high, 204 feet frontage, with two wings, and to cost about $250,000.——Dr. Frank G. Moyer has obtained a permit to erect a four-story brick sanatorium at 1500 Eutaw Place.——The St. Agnes Hospital announces the following appointments on its staff: Dr. Joseph C. Bloodgood and Alexius McGlannan, surgeons, and Dr. Guy L. Hunner, gynecologist.

MASSACHUSETTS.

Harvard Dedication.—The new buildings of the Harvard Medical School, Boston, described in The Journal, July 7, page 50, were dedicated September 25 and 26. The program of exercises included addresses by President Eliot, Dean Richardson, Professors J. Collins Warren, Thomas Dwight and Frederick C. Shattuck, and Mr. Charles A. Coolidge, representing the architects. The exercises were followed by demonstrations in the different laboratories. On September 26 at 11 a. m. an academic session was held at the University of Cambridge, with an oration by Prof. William H. Welch of Johns Hopkins University. Honorary degrees were conferred on several notable members of the profession. Many distinguished guests from American and foreign universities and scientific bodies were present. The officers of the alumni association gave an informal reception on Tuesday evening to the alumni and guests, and on Wednesday at 1:30 p. m. the triennial dinner was held in Memorial Hall at Cambridge. Speeches were by President Eliot, Governor Guild, members of the faculty of medicine, as well as by several invited guests. A further account will appear next week.

MICHIGAN.

College Opens.—The Grand Rapids Medical College opened for the school year September 17.

Hospital Founded.—By the will of the late James L. Hurley, Flint, about $10,000 will be available to establish a hospital in Flint, to be named in his honor.

Typhoid Epidemic.—The secretary of the State Board of Health is conducting an investigation as to the cause of the recent epidemic of typhoid fever in Traverse City, where 150 cases of the disease are said to have occurred.——An epidemic of typhoid fever is reported by the health officer of Menominee.

Wayne County Society.—At the annual meeting of the Wayne County Medical Society, the following officers were elected and installed: President, Dr. J. Henry Carstens; vice-president, Dr. William F. Metcalf; secretary and treasurer, Walter D. Ford, and directors, Drs. Frank B. Tibbals, Guy L. Kiefer, H. Wellington Yates, George W. Wagner and Louis J. Hirschmann.

Personal.—Dr. David J. Hale, Fairplain, has returned from Panama.——Dr. Fannie Draper, Jackson, sails for China October 11.——Dr. Robert L. Kennedy, Detroit, has been appointed superintendent of the State Tuberculosis Sanatorium, to assume charge December 1.——Dr. James D. Kennedy and Dr. William H. Price, Detroit, sailed from New York for Europe, August 24.

Ill and Injured.—Dr. Joseph Poposkey, Grand Rapids, sustained a fracture of the left ankle in a runaway accident September 10.——Dr. LeRoy Lewis, Bay City, is at the Lewis Hospital, suffering from a fracture of the arm due to a fall.——Dr. James C. Abrams, Calumet, has been confined to his house for two weeks with congestion of the brain.——Dr. A. Curtiss, Big Rapids, was struck by a truck on a station platform at Clear Water, Minn., and sustained a fractured rib.

MISSOURI.

Funds Needed to Complete Hospital.—Of the $225,000 of bonds voted for the erection of a new city hospital building in Kansas City, it is reported that less than $20,000 remain, and it is anticipated that $100,000 more will be required before the institution can be made habitable.

Temporary Restraining Order Served.—Dr. Christian H. Eyermann, St. Louis, threatened by the State Board of Health with revocation of his license, because of advertising to cure appendicitis by electricity, has obtained a temporary restraining order against the board, denying to that body the right to revoke Dr. Eyermann's license as a physician and surgeon.

NEW YORK.

Physicians Try to Aid Patrick.—A petition signed by 3,500 physicians of New York State has been presented to the governor asking that a commission of experts be appointed for the purpose of settling the disputed medical point in the Patrick case. Patrick was sentenced to die for the murder of William M. Rice of New York City, and the case is now on appeal before the United States Supreme Court. The point raised, on which the expert testimony was so conflicting, was whether the congestion of the lungs might not have been the result of the embalming fluid and not of the chloroform, which it was alleged had been administered under the direction of Patrick.

New York City.

Personal.—Dr. Henry P. Loomis arrived from Europe on the *Baltic* September 20.——Dr. and Mrs. Edward L. Keyes, Jr., sailed for Europe on the *Nieuw Amsterdam* September 19.

Death from Typhus.—Because of the death of a child from typhus fever in the steerage, the *Cretic* was held at quarantine and all passengers were subjected to a rigid examination; the first and second cabin passengers were allowed to land, but the steerage passengers were detained.

Change at St. Gregory's Hospital.—It has been announced by Ballington Booth that the Volunteers of America and St. Gregory's Society have effected a union in the management of St. Gregory's Hospital in Gold Street. The building has been remodeled and equipped during the past year at a cost of $10,000.

Less Typhoid in Brooklyn.—It is announced by the Board of Health that while there were 689 cases of typhoid reported up to the present time last year, there have been only 173 cases reported thus far the present season. This is attributed to the effect of the advice of the department to boil all drinking water.

Amend Sanitary Code.—At the meeting of the Board of Health September 19, important amendments to the sanitary code were adopted in compliance with the new pure-food law. One of the amended provisions of the code is that no person shall have, sell or offer for sale any food which is adulterated or misbranded, and the term food is defined to include every article of food and every beverage used by man, and all confectionery. The code defines adulterations very minutely.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending September 15, 351 cases of pulmonary tuberculosis, with 150 deaths; 184 cases of diphtheria, with 19 deaths; 134 cases of typhoid fever, with 18 deaths; 74 cases of scarlet fever, with 4 deaths; 53 cases of measles, with 2 deaths; 38 cases of whooping cough, with 7 deaths; 14 cases of cerebrospinal meningitis, with 5 deaths; 2 cases of smallpox and 6 of varicella, a total of 856 cases and 205 deaths.

The Trachoma Problem.—It is asserted by Dr. John C. Lester assistant surgeon of the New York Eye and Ear Infirmary, that the cases of trachoma in the public schools are so numerous that the hospitals are utterly unable to cope with them. This is attributed to the filthy conditions of the tenement-house regions, especially on the East Side, one-third of the school children there being afflicted with trachoma. It is stated that one-quarter of the school children of Brooklyn are affected. The Board of Health is coping with the situation as best it can, but the situation is said to be serious unless more hospitals are established.

NORTH CAROLINA.

Personal.—Dr. P. L. Murphy has been re-elected superintendent of the State Hospital at Morganton.——Dr. Andrew J. Crowell has returned to Charlotte after a three months' stay abroad.——Dr. H. J. Williams, Jr., Winston, has gone to Edinburgh for a year's study. He expects to locate eventually in Cape Town, South Africa.

Vital Statistics.—During July 278 deaths were reported, equivalent to an annual death rate of 18.3 per 1,000. Diarrheal diseases and typhoid fever led in the death causes. During the month measles were reported from 11 counties; whooping-cough from 30 counties; scarlet fever from 4 counties; diphtheria from 10 counties; typhoid fever from 64 counties; malarial fever from 17 counties; cerebrospinal meningitis from 6 counties; peritonitis from 2 counties; pneumonia from 7 counties, and smallpox from 13 counties.

***College Sessions* Begin.**—The annual session of the North Carolina Medical College, Charlotte, opened September 8, with an unusually large enrolment. The additions to the faculty include Dr. Edward C. Register, professor of practice of medicine, and Dr. George W. Pressly, professor of the principles of surgery. The work on the new building is progressing rapidly. ——The fifth annual session of the Medical Department of the University of North Carolina, Raleigh, opened September 14 with an address on "The Value of Character to the Professional Man," by Dr. Augustus W. Knox, professor of surgery.

OHIO.

Diphtheria.—Carlton is reported to have 125 cases of diphtheria and the churches and schools have been closed.——The school at Story and Fairview school, east of Piqua, have been closed on account of diphtheria.

Violated Medical Law.—Mrs. Lida Hazlitt, Richmond, Ind., was arraigned at Springfield, Ohio, for practicing medicine without a certificate, was found guilty of violation of the state medical law, and was fined $30 and costs, which was paid.

Section on Pathology.—Dr. Otto V. Hoffman, Dayton, advocates the inauguration of a special section in the Ohio State Medical Association for the study of pathology, along lines similar to those of the pathologic exhibits, held at the annual meetings of the national association and several of the state medical societies.

Typhoid.—Cincinnati reports 40 cases of typhoid fever for the week ended September 14.—The Columbus Board of Health has instructed the health officer, Dr. McKendrie C. Smith, to enforce the state law against physicians who do not report the cases of typhoid fever in their care. The law provides a fine of not less than $100 for the first offense.

Personal.—Dr. Martin Stamm, Fremont, left August 20 for a tour of the world. A banquet was tendered him by the medical profession of the city August 17.——Dr. Mark Milliken, health officer of Hamilton, has returned from a trip to Colorado.——Dr. Charles W. Baker has resigned as a member of the East Liverpool Board of Health.——Dr. Myron J. Ewing and family, Findlay, left for their new home in Oregon September 8.

Endowment for Library.—By the will of the late James Patterson Walker, surgeon-general, Bengal service, his library, collected during a long term of service in India and other parts of the world, has been bequeathed to the Lloyd Library of Cincinnati, together with an endowment of $30,000 in cash, to be devoted to the encouragement of original research in the practice of medicine and pharmacy, with special reference to the specific action of medicines.

Medical College Opens.—The fifteenth annual session of the Ohio Medical University, Columbus, was opened September 11. Introductory remarks were made by the chancellor, Dr. James U. Barnhill, Columbus, and addresses were made on behalf of the trustees and the faculty. The faculty changes were as follows: Dr. Henry A. Rodebaugh, instructor in nervous diseases; Dr. Albertus C. Wolfe, formerly professor of diseases of the nose and throat, professor of therapeutics; Dr. C. E. Pfeifer, instructor in dietetics; Dr. P. M. Wright, instructor in therapeutics; Dr. Harry M. Snively, assistant to the chair of physiology, and Dr. Howard M. Brundage, assistant to the chair of anatomy.

PENNSYLVANIA.

Fire Loss.—*The house of Dr. John W. Groff, Harleysville*, was struck by lightning and destroyed, September 13. The loss was about $5,000.

Will Equip Hospital Room.—Dr. Will L. Shindel, Sunbury, has advised the building committee of the Sunbury Hospital that he will equip and furnish a private room in memory of his father, the late Dr. Daniel W. Shindel.

Typhoid Fever.—Nanticoke, which suffered from an epidemic of typhoid fever last year, reported on September 11, 16 cases, with two deaths.——During the five days ended September 14, 89 cases of typhoid fever were reported to the bureau of health of Pittsburg.

Ill and Injured.—Dr. Charles D. Hunt, Williamsport, was rendered unconscious by being thrown from his carriage, September 15.——Dr. Simon P. Earnest, Belmont, who was recently operated on at the West Penn Hospital, Pittsburg, is making satisfactory progress toward recovery.

Personal.—Dr. Andrew B. Gloninger, Lebanon, sailed for Antwerp, September 10.——Dr. Herbert Fox has been appointed supervisor of the state laboratory by State Health Officer Dixon.——Dr. Sydney J. Repplier, Reading, who has been appointed physician to the United States minister to Morocco and Algeria, left August 29 for Algiers and Fez.

Vaccination Not Compulsory.—The attorney-general declared September 12 that parents can not be compelled to have their children vaccinated. A teacher is compelled to refuse to admit unvaccinated children to the public schools, or those who have not presented a certificate of successful vaccination or of having had smallpox. When children have been refused admission to schools under these circumstances and have been sent home, parents can not be fined for having their children out of school.

Philadelphia.

Bequests.—By the will of the late Mary A. Fry, the Home for Consumptives will receive $2,000.——A bequest of $500 was made to the Wills Eye Hospital by the late Annie E. Hamilton.

Personal.—Dr. Ross B. Patterson has been appointed sub-dean of Jefferson Medical College.——Dr. Thomas F. Neil has been appointed superintendent of the Blair County Hospital for the Insane.——Dr. John H. Trinder has been appointed resident physician of Girard College.

Health Report.—The total number of deaths reported for the week ended September 15 aggregated 500. This is an increase of 101 over the number reported in the corresponding period of last year, and an increase of 11 over the number reported last week. The principal causes of death were: Typhoid fever, 16; pertussis, 11; consumption, 62; cancer, 23; alcoholism, 6; apoplexy, 20; heart disease, 34; acute respiratory disease, 36; enteritis, 57; hepatic cirrhosis, 5; appendicitis, 4; Bright's disease, 40; congenital debility, 10; suicide, 4; accidents, 16, and marasmus, 16. There were 162 cases of contagious disease reported, with 20 deaths, as compared with 176 cases and 20 deaths reported in the previous week.

GENERAL.

Personal.—Brigadier General Robert M. O'Reilly, who has been surgeon general of the Army for the past four years, was reappointed to that office by direction of the President of the United States.

Health Conditions of Cuba.—Passed Assistant Surgeon von Ezdorf reports that for the week ending September 11, 5 cases of suspected yellow fever and 9 cases of dengue were reported in Havana. He states that he has been informed that the conduct of sanitary work, particularly in eradicating yellow fever, will not be discontinued, although the country is engaged in suppressing a revolution.

Pennsylvania Surgeons Meet.—The Association of Surgeons of the Pennsylvania Lines held its twenty-fifth annual meeting in Pittsburg, September 13. The following officers were elected: Dr. Richard J. Morgan, Van Wert, Ohio, president; Dr. Adam M. Beers, Newcomerstown, Ohio, vice-president; Dr. Stewart L. McCurdy, Pittsburg, secretary and treasurer, and Drs. A. I. Bouffleur, Chicago, and James G. Carr, Coshocton, Ohio, members of the executive committee.

American Surgeon in Danger.—Assistant Surgeon Walter Robertson of the United States Public Health and Marine-Hospital Service, stationed at La Ceiba, Honduras, was, according to newspaper reports, threatened with assassination as the result of reporting a case of yellow fever. For over a week he dared not leave the consulate, and during that time fifty Americans guarded the consulate to prevent an attack by the natives.

Homeopaths Elect Officers.—At the annual session of the American Institute of Homeopathy, in Atlantic City, September 13, the following officers were elected: President, Dr. E. B. Hooker, Hartford, Conn.; vice-presidents, Drs. James W. Ward, San Francisco, and W. E. Reilly, Fulton, Mo.; secretary, Dr. Frank Kraft, Cleveland; treasurer, Dr. T. Franklin Smith, New York; registrar, Dr. J. H. Bald, Bay City, Mich.; necrologist, Dr. C. B. Kinyon, Ann Arbor, Mich.; member of the board of censors, Dr. G. H. Quay, Cleveland.

Missouri Valley Meeting.—The Medical Society of the Missouri Valley held its nineteenth annual meeting in Council Bluffs, Iowa, September 6 and 7. About 100 physicians were present. It was decided to hold the next session in Omaha, in March, 1907. The following officers were elected: Dr. O. Beverly Campbell, St. Joseph, Mo., president; Drs. William F. Milroy, Omaha, and C. O. Thienhaus, Milwaukee, vice-presidents; Dr. Charles Wood Fassett, St. Joseph, Mo., secretary (re-elected), and Dr. Donald Macrae, Council Bluffs, Iowa, treasurer (re-elected).

To Purify State Streams.—The representatives of the state health and sanitary engineering departments of New Jersey, Pennsylvania and New York held a joint meeting in Atlantic City, September 14, and adopted plans for the three states by united action to stop the pollution of the Delaware River. New Jersey has been at work five years on this project and has already accomplished much on the upper waters by compelling cities and towns to install modern sewerage disposal plants. Pennsylvania and New York have started on the same course, but the three states agreed that by working together the desired object can be more easily obtained. Those at the conference were: Col. Charles W. Fuller, chairman of the sewerage commission of New Jersey; Dr. Samuel G. Dixon, state health commissioner of Pennsylvania; Herbert Snow, chief sanitary engineer, Department of Health, Pennsylvania; Harry M. Herbert, engineer of New Jersey commission; Theodore Horton, engineer, New York Department of Health; A. H. Seymour, secretary, New York Commission of Health, and Wilbur Morse, secretary, Pennsylvania Commission of Health.

Cholera in the Philippines.—A particularly disquieting feature of the situation in the provinces, according to *Public Health Reports*, is that cholera has traveled overland over the new road which has recently been opened from the province of Laguna to the sea. The disease made its appearance almost simultaneously at the ports of Pagbilao and Lucena, in the province of Tayabas. Owing to the fact that it is impossible to give that careful attention to outgoing vessels leaving these ports which is given to vessels leaving Manila, it is feared that the disease may be carried by small sailing vessels to nearby islands, from which it may again spread throughout the Philippine Archipelago, as was the case in 1902. The bureau of health has taken vigorous measures to combat the outbreak at the ports of Tayabas province. While the disease has not been entirely stamped out in the ports, yet there has been a reduction in the number of cases and no spread to other ports. The impression is that if the disease can be confined to the same territory which it has occupied during the past year, which section is embraced within an area of 75 miles from Manila, the chances of entirely eradicating it during the next dry season are very good; but if the disease should now gain another foothold in the southern islands it would probably be several years before it could be successfully eradicated.

CANADA.

Typhoid Fever in Montreal.—A total of 63 cases of contagious diseases was reported in Montreal during the week ended September 8. Thirty of these were typhoid fever; 15 were tuberculosis.

Personal.—Dr. R. D. Sanson, Calgary, Alberta, is visiting in Toronto.——Dr. W. D. Ferris, Edmonton, Alberta, has been visiting in Vancouver.——Dr. R. H. Craig and Dr. Austin Irvine, Montreal, have returned home from a trip to Toronto, New York and Atlantic City.——Dr. R. A. Pyne, minister of education for Ontario, has returned from a three months' trip to the old country.——Drs. McMurtry, McDonald and Scott, Montreal, are leaving for China as medical missionaries. Dr. McDonald, who has been in the field before, works specially in Canton, whence come most of the Chinese in Montreal.

Tuberculosis Sanatorium for British Columbia.—The Rev. Dr. Moore of Ottawa, secretary of the Canadian Association for the Prevention of Consumption, has been in British Columbia in the interests of his association. At a public meeting, September 7, Dr. Underhill, the health officer of Vancouver, and Dr. C. J. Fagan, Victoria, the health officers of the province, and Dr. Moore made addresses. Dr. Fagan said that the lieutenant-governor, Mr. Dunsmuir, had contributed $10,000 for a sanatorium for the province; that the provincial government had given $5,000; the Canadian Pacific Railway, $5,000, and numerous private individuals, $2,500. It is desired to raise $50,000 before the work is proceeded with.

Proposed Department of Public Health in Ontario.—About a year ago, in a paper read before the annual meeting of the Ontario Medical Association, Dr. Charles A. Hodgetts, secretary of the Ontario Board of Health, advocated the creation of a separate department of public health under a responsible minister. The matter was fully discussed at a meeting of the Ontario cabinet recently. If such step is taken it is likely that the Hon. Dr. Willoughby, a minister now without portfolio, will be placed at the head of the department, and the present secretary, Dr. Hodgetts, made deputy minister. As the board of health is to be reorganized, it is altogether likely that it will take shape in the direction above indicated.

FOREIGN.

Nostrum Regulations in Australia.—The regulations of the Victoria (Australia) board of health with regard to the labeling of secret remedies containing poisons will go into effect Jan. 1, 1907, instead of October, 1906, in order to give British and American manufacturers time to comply with the new requirements.

Central Office for Research on the Brain.—It is announced that the Senckenburg Neurologic Institute at Frankfurt a. M., Germany, has been appointed the headquarters for international research on the brain. The committee making the appointment is an offshoot of the International Association of Academies of Science.

Prizes for Nursing Mothers.—The city of Leipsic, Germany, has decided to give money prizes to women who nurse their infants. Prizes are also to be given to midwives who distinguish themselves by aiding and persuading women to nurse their children. The prizes are supposed to take the place of any loss of earning capacity because of nursing.

Pawlow to Lecture in London.—The sixth Huxley lecture will be delivered October 1 at London by Prof. I. P. Pawlow, professor of physiology at St. Petersburg. His subject is to be "Recent Advances in Science and Their Bearing on Medicine and Surgery." It will be remembered that he received one of the Nobel prizes in 1904, for his classic discoveries in the physiology of digestion.

Plague in Turkey.—Consul Jewett writes from Trebizond that 4 cases of plague, with 1 fatal, were reported in the prison at that place, August 8. Eight cases and 3 deaths were officially reported up to and including August 18. The prison is situated near the other government buildings in the center of the city. It contains 700 prisoners crowded together in seven rooms that give not more than 10 square feet of floor space for each inmate. The sanitary condition of the prison is of the worst type. As the local authorities were dilatory, the consuls of the nine powers represented at Trebizond held a meeting and requested the governor-general to adopt vigorous measures to protect foreigners and commerce.

Effect of Plague and Malaria on the Birth Rate in India.—The sanitary authorities in the Punjab state that the influence of plague on the birth rate is of an indirect and general nature only; and that in spite of the fact that there were 334,897 deaths from plague in 1905, the birth rate in the Punjab rose from 41.5 to 44.4 per thousand of the population. The *Journal of Tropical Medicine* states that it is quite noticeable that more women than men die of plague in the Punjab, a fact probably owing to women being secluded indoors and therefore more in contact with the sources of infection. The birth rate would seem to be lessened more markedly by the prevalence of malaria than of plague. A severe malarial outbreak in the autumn is reported to affect the birth rate in the following year more than any other form of disease. For four years in succession the death rate in the Punjab has been higher than the birth rate; and the Punjab has recently had the highest death rate of any district of India, amounting to no less than 47.55 per thousand.

Syphilis in Turkey.—The Constantinople correspondent of the *Lancet* states that the spread of syphilis and venereal diseases is reported from several parts of Sivas. The sanitary inspector of the province has asked the central authorities of Constantinople promptly to adopt all the necessary measures in order to check the propagation of the malady and to treat the sufferers. It is intended to build in Sivas itself a hospital with 50 beds for syphilitic and venereal patients. Two medical men will be appointed with a salary of $60 a month. Their duty will be to visit all the contaminated localities and to render gratuitous assistance to all seeking such. They will also receive a proportionate sum for traveling expenses and for drugs and instruments. Similar measures have been adopted in other provinces.

The Antiquackery Campaign.—The efforts of those interested in the antiquackery movement in Germany have already borne fruit, as can be seen by the various numbers of the organ of the Antiquackery Society, *Hygienische Blätter*. The last number relates that a "nature healer" has recently been sentenced by the Elberfeld court under the following circumstances: He had prescribed homeopathic pills and warm baths to a woman with uterine cancer who had been urgently advised by her physician to have the growth removed at once. After the death of the woman the nature healer was condemned by the court to nine months' imprisonment. Another sign of progress is shown in the action of the Frankfurt "*Kleine Presse*," a lay paper, which received an advertisement for insertion accompanied by a considerable sum of money, setting forth the virtues of "coza powder," a cure for inebriety sent out by the "Coza Institute" in London. The advertisement stated that free samples would be sent on demand. The paper sent for a free sample under another address; with the sample came two boxes of the powder, C. O. D., for $5. The boxes were returned by the consignee, but by return mail one box was sent him with the statement, "one box alone is sufficient to cure in many cases," price $2.50. The paper returned the advertisement and the accompanying money, declining to do business with the Coza Institute, but writing up the affair in detail for its news columns, with appropriate comment.

LONDON LETTER.

(From Our Regular Correspondent.)

Infantile Mortality and Health Visitors.

The value of women as health visitors has been proved by an experiment at Limehouse, one of the poorest districts of the East End of London, where the infantile mortality stood at an alarming height. For some time the proposal to appoint health visitors was under consideration, but the borough council would not incur the expense. The need for a health visitor was so great, because of the ignorance among mothers as to the rearing of babies, that a private individual agreed to pay the salary of such an officer for two years. Her duty was to visit the homes of the mothers and give instructions as to the proper feeding of infants. At first she was looked on with suspicion, which she conquered by tact and ability. Reporting on her work the health officer says: "She visited and revisited the homes of 721 infants, 74 of whom died under the age of one year. The rate of mortality among the infants she visited was, therefore, 102 per 1,000 births. This is very satisfactory, considering that the area was selected on account of its high mortality and that the infant mortality for the whole district was 185 per 1,000 births." She pointed out the disadvantages of the bottle with the long tube and diminished the extent to which it was used. She also did her best to abolish the use of the dummy teat which, no matter how dirty, was inserted into the child's mouth whenever it cried and the feeding bottle was not at hand.

Mistakes in the Diagnosis of Fevers.

The annual report of the Metropolitan Asylums Board for 1905 contains the usual statement of the mistakes made by doctors in sending cases into the fever hospitals. Of the total admissions 9 per cent. (as compared with 10.7 in 1904) were found not to be suffering from the diseases mentioned on the medical certificates on which they were removed to hospital. There were 975 cases wrongly certified as scarlet fever. Of these, 96 were measles, 90 rubella, 106 tonsillitis, 147 erythema, 143 had no obvious disease and 149 were not diagnosed. There were 908 cases wrongly certified as diphtheria. Of these, 52 were measles, 544 tonsillitis, 55 had no obvious disease and 22 were not diagnosed. There were 247 cases wrongly certified as typhoid fever. Of these, 27 were influenza, 6 general tuberculosis, 64 pneumonia and 6 had no obvious disease. In the case of smallpox the mistakes formed a high proportion: 32 out of 74 admissions. The explanation is obvious. In recent years smallpox has become so rare that many doctors have never had an opportunity of seeing a case.

Lunacy in Ireland.

The special report of the inspectors in lunacy as to the large increase of lunacy in Ireland has been issued. The following conclusions have been arrived at: 1. The population of the country has decreased, but, while the number of insane has increased, the statistics do not offer precise grounds to put forward a definite opinion. 2. Without affirming that there has been no increase the inspectors conclude that the increased number is largely due to accumulation in public asylums. 3. The increase has occurred among the poor. 4. The increased number in asylums is due to accumulation and decreased discharges and deaths, to widening of medical opinion as to insane persons who should be confined, to the greater confidence in asylum treatment and the increase in the number and accessibility of asylums, to the great longevity owing to improved sanitations, and to the influx of returned emigrants broken down mentally. 5. The statistics of insanity in other countries, more, even, than those in Ireland, point to the fact that, notwithstanding their undoubted intellectual gifts, the Celtic race is prone to mental disease. 6. Next to heredity, intemperance heads the list of causes of insanity. General paralysis of the insane is on the increase, though in the rural districts it is practically absent.

The Use of Diachylon as an Abortifacient.

The use of lead as an abortifacient is a practice which was unknown in this country until 1893, when it was first described by Dr. Pope of Leicester, who reported two fatal cases. Subsequently other cases were published, principally in the Midlands. In 1901 the process extended to Sheffield, where it became very prevalent. The lead was taken in the form of diachylon plaster or in patent "female pills." In and around Nottingham an increasing use of diachylon as an abortifacient among the working classes has been recently observed. The attention of the city authorities was directed to the subject, and it was found that in cases of abortion pills described as "Mrs. Seagrave's pills" had been taken. Mrs. Seagrave (*alias* Wardle) was found to be doing an extensive trade in the sale of these pills, both to married and to unmarried women. A box of pills was obtained by an agent of the health department and found to contain from 50 to 70 per cent. of diachylon, aloes and an outer coating of boric acid. The pills were roughly made and varied in weight from 1½ to 5 grains. Mrs. Wardle was arrested and a large quantity of pills and implements for making them were found in her house. She was brought before the magistrates and three witnesses were produced who had bought pills from her, became seriously ill after taking them and aborted. The medical evidence showed that they suffered from lead poisoning. Mrs. Wardle was committed for trial at the assizes, where the women who had purchased the pills stated that she had instructed them to take a dose of Epsom salts, fasting in the morning, then four of the pills, and four of the pills again at night. For the defense it was stated that Mrs. Wardle had no idea that the pills were harmful and that she had sold them not for the purpose of procuring abortion, but only as "female pills" to be taken in cases of irregular and suppressed menstruation. Several witnesses were called, both male and female, who stated that they had taken the pills and derived benefit from them for such ailments as bad backs, internal pains and anemia. To rebut the last statement the health officer was called and stated that anemia was one of the earliest and most constant symptoms of lead poisoning and that lead would aggravate instead of benefiting anemia. The judge in summing up said that it was difficult to reconcile Mrs. Wardle's statement that she was not aware of the harmful effects of diachylon with the fact that she had advised her clients in every instance to take Epsom salts, which were an acknowledged eliminator of lead. She must have known that diachylon contained lead. She was found guilty, but recommended to mercy, and sentenced to eighteen months' hard labor. The judge said that he wished it to be clearly understood that the offense was a felony for which the maximum penalty was penal servitude for life.

VIENNA LETTER.

(From Our Regular Correspondent.)

Union of Medical Representative Clubs in Austria.

An important evolution in the organization of medical practitioners took place a short time ago when at a meeting of the delegates of nearly all the medical clubs a uniform and unanimous basis for work was arrived at. In order to understand the difficulties and obstacles that have prevented hitherto a complete organization of the profession in our dual empire, Austro-Hungary, it must be kept in mind that no fewer than nine different nations and languages are combined to form this one realm. Racial and religious differences were so powerful, even in the capital itself, that the 2,800 doctors of Vienna were not found unanimous in the fight against bureaucratic arrogance two years ago, when the governor dissolved the "Aerztekammer" and ordered a new election of that medical representative body. Matters have improved since, and the organization has proved such an influential agent in attaining minor results that at last all obstacles have been overthrown and now the entire body of the practitioners in Austria, some 12,000 men, are practically brought under one hat. In all matters pertaining to the general condition of medical men, to hospital education, appointments, to ethics and legislative representation the newly formed union will proceed hand in hand with the clubs and accept the ideas proffered by each single rural branch. The first trial of the working order of the union was made in the organization of the strike of the country practitioners of Lower Austria, when the union had to prevent "blacklegging," in which endeavor it had full success. Although the conflict between the country doctors and the state is still raging, not a single case of strikebreaking has been noticed. There are two more points where the union will have to show its power. One is contract practice, which a law promulgated 18 years ago made compulsory for all persons employed in factories and business concerns. Through the absence of even the rudiments of organization at that time, medical influence could not be brought to bear on the proposed bill, and the interests of the doctors were sacrificed to the convenience of the tradesman. The present year has already seen the first conflict between the organization and some clubs. The other point, where a change is urgently wanted, is the condition of the hospital staff, which, in its majority, is unpaid, except the professors and senior assistants. As the "output" of the universities is so large, the numerous M.D.'s turned out yearly are glad to be able to work at a hospital. Thus the state employs the hands and minds of hundreds of young doctors without paying for it. This increases the difficulties, which are already large enough, in the path of the young doctor, who is anxious to find his living by work for which he has been educated. The union will take the matter in its hands and will most likely cause a strike among the juniors until the state finds the money.

A New Children's Hospital.

By a munificent gift from a private individual, a new hospital for children has been erected at a cost of about 600,000 kronen ($120,000). It has been added as a separate pavilion to the existing Franz Joseph Hospital, so as to save the expense of a separate administrative staff, but otherwise it is quite an independent hospital, equipped with all the latest and most modern appliances for scientific work. At present it will accommodate 100 in-patients, but its capacity will shortly be increased to thrice this number. It is meant first for emergency cases, and will be open free of charge to all such.

Correspondence

Somnos.

We give space to the following letter so that the H. K. Mulford Company cannot say that we are not treating it fairly, although much of the letter is a repetition of what has been stated before. There is no use in attempting to befog the question:

Philadelphia, Sept. 19, 1906.

To the Editor:—Had your report of the findings on "Somnos" (Elixir Trichlorethidene Propenyl Ether, Mulford) been confined to that product, we might not have felt called on to address this letter of protest, even though prejudice is shown in the treatment of the subject.

You have seen fit, in The Journal of the American Medical Association, September 15, to attack the integrity of the H. K. Mulford Company and seriously to injure our reputation as a manufacturing house. To this we take strong exception. As your charges are based on what we have said on labels and in advertising circulars concerning "Somnos," we herewith briefly relate the history of its introduction:

Some six years ago two chemists, Dr. Albert C. Barnes, a graduate of the University of Pennsylvania, and Dr. Herman Hille, a graduate of the University of Heidelberg, who were at that time engaged in original research in our scientific department, presented to us a chemical product to which they gave the name chlorethanal alcoholate, as expressing its chemical description, and the symbolic formula $C_5H_{11}O_6Cl_9$, giving its composition. A study was made of its physiologic properties and sufficient clinical data obtained to convince us that we had an important drug which had never before been investigated as a therapeutic agent

Realizing the importance of having these experiments verified by impartial and competent observers, we communicated with the University of Pennsylvania, July 30, 1902, requesting that physiologic experiments be undertaken on this product, and Dr. Colin C. Stewart, then one of the demonstrators in that institution, and now associate professor of physiology at Dartmouth Medical College, undertook the work.

Following are copies of several letters written by us in correspondence with Dr. Stewart at the time:

July 30, 1902.

Dr. C. C. Stewart, University of Pennsylvania, care Physiological Department.

Dear Sir:—Will you kindly advise if you are in a position to take up the investigation of a product (Somnos) which we have, and determine its physiologic action. We are desirous of having our own laboratory tests confirmed.

Will be glad to have you communicate with us at an early date.

February 4, 1903.

Dr. C. C. Stewart, Physiological Department, University of Pennsylvania.

Dear Sir:—We are particularly anxious to have the experiments at some reliable institution or hospital carried out in connection with the physiologic work you are doing—the remedy is one of such importance to the physician that its complete physiologic action should be determined at as early date as possible.

Dr. Stewart's experiments and investigations covered a period of about a year, and fully verified our claims, namely, that Somnos was a hypnotic, differing essentially from chloral in that in medicinal dosage it had no depressing effect on the heart and circulation, amounts equivalent to over 1,000 c.c. (33 fl. oz.) of the elixir (Somnos) for a 150-pound man having been injected intravenously in animals without lethal effect, the lethal dose at that time not being determined. We were, therefore, amply justified in making the claims which appeared on labels and in our brochure on "Somnos."

In December, 1905, we submitted Somnos to the American Pharmacologic Society, Prof. Reynold Webb Wilcox, president of the association having become interested in the clinical use of Somnos, having used the drug since May, 1904, in the treatment of seventy-two cases. Samuel P. Sadtler, Ph.D., LL.D., professor of chemistry at the Philadelphia College of Pharmacy, chemical editor of the U. S. Dispensatory, one of the committee of revision of the U. S. Pharmacopeia, and one of your Comcil on Pharmacy and Chemistry, was selected by the society to verify the chemical claims for the product. He substantiated the claims of our chemist and found it to be chlorethanal alcoholate, a definite chemical compound, with the symbolic formula $C_9H_{11}O_6Cl_9$, as claimed and devoid of free chloral. This verified our claim that chlorethanal alcoholate is a synthetic compound. Dr. Sadtler, however, suggested that the name "trichlorethidene propenyl ether" be used in place of chlorethanal alcoholate, since the latter was usually used to designate compounds of ethyl alcohol and not polyatomic alcohol.

Up to this time we had expressed the chemical composition of Somnos in technical language, not for the purpose of deceiving the medical profession, as charged by you, but to protect our interests, since the product was not patented.

Professor Sadtler's report, covering four months' investigation, was published in Bulletin No. 1 of the American Pharmacologic Society, and copies sent to you.

After Professor Sadtler's report was published in the bulletin we changed our labels and literature to conform to his suggestions by using the name trichlorethidene propenyl ether in place of chlorethanal alcoholate.

Following are copies of the label used prior to the report and subsequent to it:

EXHIBIT 1.

MULFORD'S SOMNOS,

(Chlorethanal alcoholate) $C_9H_{11}O_6Cl_9$.

Reliable and Safe Hypnotic and Cerebral Sedative.

Indications: In insomnia Somnos is the ideal hypnotic. It is especially valuable in the sleeplessness attendant upon hysteria, "nervousness," neuralgia, typhoid fever, pneumonia, la grippe, alcoholism and mental diseases.

Directions: One to two tablespoonfuls in a half glass of water or milk one or two hours before bedtime, repeated if required. For children, one-half to one teaspoonful, according to age.

H. K. Mulford Co., Chemists, New York, Philadelphia, Chicago.

EXHIBIT 2.

MULFORD'S SOMNOS (word-mark).

(Elixir Trichlorethidene Propenyl Ether)
(Formerly known as Chlorethanal Alcoholate).
Hypnotic, Cerebral Sedative and Antispasmodic.

Dose.—Adults, as a hypnotic, 1 to 2 tablespoonfuls repeated every hour or two, or as required. As a sedative, dessert to tablespoonful in a half glass of water or milk. Children ¼ to 1 teaspoonful, according to age.

H. K. Mulford Co., Chemists, New York, Philadelphia, Chicago.

Prof. Colin C. Stewart was engaged by the society for the physiologic investigation. His report, published in the bulletin, shows that the elixir (Somnos), is not depressant, even when given in six times the prescribed hypnotic dose; that the lethal dose, judging from its effect on dogs, is not less than 16½ fluid ounces. This report verified his previous investigations, made at the University of Pennsylvania in 1902 and 1903.

Professor Stewart's earlier work was published, but by his request was afterward withdrawn. You, however, were advised that the work had been done and fully acquainted therewith. Furthermore, you were furnished a copy of Professor Sadtler's report and a copy of Professor Wilcox's clinical report.

You state that we refused to be guided by your suggestion, yet we had no knowledge of the result of your investigation until your virulent attack was made in The Journal, September 1 and 15. From a communication received under date of Feb. 21, 1906, and signed by you, we quote:

> Three preparations are mentioned (in your advertisement) that have not been acted on (by the Council) Protan, Proferrin and Somnos, but my opinion is that that they will be approved for advertising in the form in which they now appear in the copy.

From the fact that an advertisement was accepted and published, inference is natural that our claims for Somnos had been found correct.

In you issue of September 15 you state:

> The attention of the officers of the Company was called to the matter (of Somnos), and it was hoped that they would submit a plain statement regarding the composition of the preparation and modify the literature to conform to the actual facts. This they did not seem inclined to do, at least they did not do it.

Every request for information from you for your Council has been freely and at once answered, and all additional data in our possession promptly furnished. No request was received from you to modify our literature in any way. How could you make such a request before you had your data? Why should we modify our claims when we were possessed of the facts mentioned, and in addition possessed voluntary communications from physicians above reproach supporting our stand?

On receipt of Professor Sadtler's report, our labels and literature were changed at once to conform therewith, and you were advised thereof. We did not change our labels and literature after statements had appeared in The Journal that Somnos is a mixture of chloral and glycerin, or a combination of the two held together so loosely as practically to amount to the same thing, because the only way to determine the truth of this statement was by physiologic and chemical investigations, and then we had in our hands such data to support our claims.

Prof. Colin C. Stewart's report states:

> In many instances in dogs it has been found impossible, within the limits of human endurance, to produce death in the manner described. Thus in one case 114 c.c. of the elixir (Somnos) were injected intravenously, and 30 c.c. administered by the stomach, in the course of three and three-quarter hours without fatal result. This total of 144 c.c. for the animal in question represented a dose of 11.75 c.c. per kilo, or fifty-one times the prescribed dose of 0.23 c.c. per kilo, corresponding to a dose for a 70 kilo man of 822.5 c.c. of Somnos, containing 45.24 gm. (696.7 grains) trichlorethidene propenyl ether, chemically equivalent to 42.02 gm. (647.1 grains) hydrated chloral.
>
> In two other dogs (II and III) the lethal doses were 68 c.c. and 108 c.c. respectively, corresponding to thirty-three and fifty-seven times the prescribed dose of 0.23 c.c. per kilo of body-weight.
>
> This is equivalent to doses, for a 70 kilo man, of 532.2 c.c. and 919.2 c.c. Somnos, containing respectively 29.27 gm. (450.8 grains) and 50.56 gm. (778.6 grains) trichlorethidene propenyl ether, chemically equivalent to 27.18 gm. (418.6 grains) and 46.96 gm. (723.2 grains) of hydrated chloral.
>
> The lowest lethal dose for dogs, representing for a 70 kilo (150 pounds) man 488 c.c., of Somnos, contains 26.83 gm. (413.2 grains) of thrichlorethidene propenyl ether, chemically equivalent to 24.92 gm. (383.8 grains) of hydrated chloral.

These results could not have followed if Somnos was a mere solution or mixture of chloral in glycerin, or if Somnos resolved itself into chloral and glycerin on being taken. What hypnotic drug can with safety be administered in thirty-three times the normal dose?

Tests were not made with equivalent amounts of chloral for the reason that Somnos is not chloral, nor does it contain any free or uncombined chloral.

If reports made to us are correct, our conclusions must stand; if they have been incorrect, we are interested, and will gladly subscribe to results if observations are from competent observers.

The above statement regarding the commercial introduction of trichlorethidene propenyl ether (Somnos) is true; therefore, you and the Council should withdraw the charge of fraudulent intent. It would seem also a mere measure of justice that the Council publish the names of the investigators who did the work on which its report is founded. The question of the therapeutic value of any drug can only be settled by a collective investigation of the product in which the observations of competent investigators are repeatedly verified, and we are perfectly willing to abide by the results of such an investigation.

We now ask you to retract your statements:

1. That our house has "stooped to dishonest or unfair practices."
2. That Somnos is not a definite chemical product.
3. That Somnos contains free or uncombined chloral.

How can the work of Professor Sadtler on the chemistry, Prof. Colin C. Stewart on the pharmacology, the report of Professor Wilcox on the therapeutic value of Somnos be entirely ignored? Further than this, how can you subscribe to the statement that we have refused information when your letter files and ours, show abundant proof that the same has been fully offered and sent you.

We are justified in asking that the question of the pharmacologic and therapeutic results be submitted to a body of competent experts in physiologic therapeutics, to be mutually agreed on, and the results published in The Journal.

H. K. Mulford Company,
Milton Campbell, President.

The Journal is asked to retract the following statements:

(1) "That our house has stooped to dishonest or unfair practices."

(2) "That Somnos is not a definite chemical product."

(3) "That Somnos contains free or uncombined chloral."

Replying to 2 and 3 first. We have in no place claimed that Somnos is not a chemical compound, but have repeatedly referred to it as such; and we have never asserted that it contains free chloral, or chloral hydrate. We have only claimed that which the H. K. Mulford Company itself now admits to be the case, viz.: That Somnos is an unstable compound of chloral and glycerin which decomposes into its elements, chloral and glycerin, at about 104° F. Sadtler, in his report on the chemistry of Somnos, says:

> The isolation of a definite compound resulting from the reaction of chloral on glycerin seems to be almost impracticable owing to its instability.

The Council has shown that the physiologic effects of chloral glycerate (Somnos) are identical with those of a corresponding amount of chloral hydrate. Mulford's letter states that Prof. C. C. Stewart (who performed the physiologic tests for the firm) did not make tests "with equivalent amounts of chloral." So long as the physiologic action of Somnos is the same as that of an equivalent amount of chloral (and the H. K. Mulford Company admits that it has no experiments to disprove this conclusion of the Council) it matters little whether or not it is a definite compound. We repeat that we have only stated what Mulford now admits: viz., that Somnos is an unstable compound. In fact, Frænkel in "Arzneimittelsynthese," p. 444, Edition 1906, states of chloral derivatives:

> Only such compounds from which chloral is easily regenerated have the hypnotic effect, whereas more stable compounds have often a strong toxic effect, without the equivalent hypnotic effect of chloral.

Also, p. 446:

> Only such chloral derivatives act as hypnotics from which the organism can split off the active chloral. The others act, owing to their chlorin content, as poisons, but not as hypnotics.

If the H. K. Mulford Company does not like the first alternative, we are satisfied to let it take the second.

It is requested that we retract our statement that "To say the least, it has not been honest and square in the matter." We would like to believe that the firm wanted to be "honest and square," and that it was misled in some way. How can we, however, when we consider the following:

While it was possible to express in simple English what this preparation is, "chloral glycerate" or "an unstable compound of chloral and glycerin," the firm put it out under the name "chlorethanal alcoholate"—a name which it now admits to be incorrect or misleading.

Apparently no thought was given to the physician on whom rested the responsibility of prescribing the drug; and this is a grave responsibility, both moral and legal, when it concerns a drug so toxic as chloral hydrate. Was this "honest" or "square"? Later, although admitting that Somnos is an unstable compound of chloral and glycerin and even pointing out the analogy between it and the compounds of chloral with water (ordinary chloral hydrate) and alcohol (chloral alcoholate) the firm, instead of stating this plainly to the physician, calls it "trichlorethidene propenyl ether"—a name which will not enlighten one physician in ten thousand, whereas the obvious name, chloral glycerate, would not be misunderstood by one physician in ten thousand.

Chloral plus water makes chloral hydrate.
Chloral plus alcohol makes chloral alcoholate.
Chloral plus glycerin makes chloral glycerate.

We are told:

> Every request for information from you for your Council has been freely and at once answered, and all additional data in our possession promptly furnished.

What was desired and hoped for was that the H. K. Mulford Company would publish to physicians a "plain statement regarding the composition of the preparation and modify the literature to conform to the actual facts." This it did not do and has not done.

The letter states:

> We had expressed the chemical composition of Somnos in technical language . . . to protect our interests.

This then is the firm's excuse for using as a description of Somnos chemical terms unintelligible to physicians. Accepting the truthfulness of this excuse we leave it to others to judge of its sufficiency. In plain English, terms are used that a chemist could understand, at least if he were sufficiently interested to look into the matter, but which not one physician in ten thousand could decipher. The chemist, however, and not the physician is the one who would imitate the preparation if any one did. To put it in other words, the H. K. Mulford Company claims that to protect itself against chemists it uses a nomenclature which chemists can understand, but which is unintelligible to physicians. But accepting this as the reason, it shows to what extent the spirit of gain is affecting our sense of right and wrong, when such an excuse can be calmly offered for not informing physicians of the character of the preparation.

So far as we can discover from the literature, Somnos was put on the market without a word to indicate whether it was a 5 per cent or a 20 per cent or a 50 per cent solution, or the pure chloral glycerate. Somnos was offered to physicians in such a way as not to indicate to them in any intelligible fashion that it was in any way related to chloral. Physicians must have prescribed it under the impression that it was the pure substance, since the synonym "chlorethanal alcoholate, $C_5H_{11}O_4Cl_3$," appeared directly under the name "Somnos" on the label and in the circulars. Was this "honest" or "square"?

The firm has been claiming that Somnos possesses "the hypnotic qualities of chloral without its untoward effects;" that it has "no toxicology;" that it is "harmless in twenty times the dose prescribed," etc., etc. (see brochure "Somnos"). It now states (see above letter) that "tests were not made with equivalent amounts of chloral" and C. C. Stewart (their own expert) states "twenty times the normal dose must be considered as an extremely dangerous quantity." Was it "honest" or "square" to the physician to make such reckless statements about the harmlessness of Somnos?

The letter asks:

> How can the work of Professor Sadtler on the chemistry, Prof. Colin C. Stewart on the pharmacology, the report of Professor Wilcox on the therapeutic value of Somnos be entirely ignored?

To this we answer: (1) Prof. Sadtler's work confirms what we have been maintaining, viz., that Somnos is an unstable compound of chloral and glycerin; Sadtler says that "the isolation of a definite compound resulting from the reaction of chloral on glycerin seems to be almost impracticable, owing to its instability," although he is satisfied that he showed that such a compound exists. (2) To show that we did not ignore C. C. Stewart's report, we quote the following from the article, the "Pharmacology of Somnos," The Journal, A. M. A., Sept. 15, 1906, p. 873:

> The writer (Stewart) states, page 19 (*Bull. Amer. Pharm. Soc.*): "As nearly, therefore, as can be determined by experiments on the lower animals, twenty times the normal dose must be considered as an extremely dangerous quantity."

To this we added:

> Yet this firm has been sending broadcast throughout the country the statement that Somnos is "harmless in twenty times the dose prescribed."

We also commented on the fact that Stewart reports no experiments on the toxicity of chloral hydrate. We considered every statement Stewart makes and repeated his experiments and found that while large amounts of Somnos may be injected into animals, slightly larger amounts of a 5 per cent solution of hydrated chloral could be given before death resulted. The experiments of the Council show that chloral hydrate is safe up to a certain point and Somnos is safe up to the same point. Equivalent doses have practically the same effect in producing sleep, in depressing the heart's action, in depressing the temperature, and in producing death. Bearing the above in mind, and remembering that the firm admits now that no comparative tests were made with chloral hydrate, was it "honest" and "square" to publish the following comparative statements, which we copy from Mulford's advertising booklet, "Somnos:"

CHLORAL HYDRATE.	SOMNOS.
Acute poisoning.	Harmless in twenty times dose prescribed.
Deep coma.	Coma unknown.
Weak, irregular, slow, feeble pulse.	Heart never depressed, pulse strong, regular and full.
Diminished respiration and lividity.	Respiratory center stimulated, rather than enfeebled.
Destruction of red corpuscles.	No effect on the blood.
Abolition of reflexes.	Cerebral effects never so profound.
Skin cold.	Skin warm.
Temperature subnormal.	Temperature uninfluenced.
Chronic poisoning.	No toxemia.
Craving soon established.	Craving never established.
Gastrointestinal irritation.	Always absent.
Erythematous eruptions.	Unknown.
Dyspnea.	Respiration ever calm.
Disturbed mental equilibrium.	Mentality clear, sensorium normal.
Somnos has no Toxicology.	Somnos habit is unknown.

(3) As regards Professor Wilcox's report, we prefer to postpone comment until physicians compare the results obtained with a 5 per cent. elixir of chloral hydrate with those obtained with Somnos (a 5 per cent. elixir of chloral glycerate). So long as the strength of Somnos was held as a "trade secret," comparisons with other hypnotics had little value. Professor Wilcox closes his report by saying, "evidently, we are closely approaching *the standard hypnotic which I postulated in 1897.*" In a circular issued by Parke, Davis & Co. we read this, also written by Professor Wilcox in 1900: "*Chloretone is our closest* approximation to that theoretical hypnotic toward which we have been led through a study of the working hypothesis of the sleep-phenomenon."

As regards Mulford's proposition to have our experimental observations repeated and verified by competent investigators, we should gladly welcome such an investigation and publish the results, of course, provided that the investigation be carried out in scientific detail and parallel experiments be made with equivalent quantities of chloral hydrate and chloral glycerate (Somnos). We would suggest as a first, and presumably a *final*, step, that Professor Stewart, who has already done the experimental work for the H. K. Mulford Company, be requested to carry out the parallel experiments.

Finally, we suggest that physicians who are in the habit of using Somnos compare the action of Somnos with that of chloral hydrate, remembering that 15 c.c. (one tablespoonful) of Somnos contains the equivalent of 0.75 gm. (12 grs.) of chloral hydrate.

Tastes of Mosquitoes.

Philadelphia, Sept. 15, 1906.

To the Editor:—The editorial reference in The Journal, September 15, page 865, to some observations on the preferences of mosquitoes in the matter of clothes, leads me to call attention to a source of error in such experiments. Some years ago a bulletin of the Hygienic Laboratory of the United States Public Health and Marine-Hospital Service detailed experiments on different colored stuffs with a view of determining if mosquitoes possess color preferences. I have not the bulletin at hand, but my recollection is that yellow was found to be least sought.

The error that enters into such tests is that the avoidance of some colors may be due to the odor of the dyestuff and not to the color. Many of the yellow colors now in use are nitro-derivatives, and even a very minute exhalation of a nitro-compound would be likely to be objectionable to the insect. Apart from this, many of the coal-tar dyes have perceptible odors, particularly when warm. Henry Leffmann.

Interstate Reciprocity and Frauds in Medical Schools.

San Francisco, Sept. 18, 1906.

To the Editor:—In The Journal, September 1, is a letter from Dr. Dudley Tait bearing the above title. The first portion of Dr. Tait's letter will be passed over and only that portion reviewed which deals with the case of Mr. Painton and the College of Physicians and Surgeons of San Francisco.

A portion of the truth may sometimes be so manipulated as to be more unjust and a greater misrepresentation than a direct falsehood. Mr. Painton is a graduate of an accredited high school. He is also a graduate of one of the *California* state normal schools. In addition to that, he has done much post-graduate work in scientific and literary branches. That places him above the required standard of the present California medical law in regard to his preliminary education. At the time that Mr. Painton matriculated in the College of Physicians and Surgeons he was justly entitled to advanced standing in certain branches, which advanced standing was not then prohibited, either by law or by regulation of the state board. The College of Physicians and Surgeons was then giving a continuous course of instruction, which plan of instruction is still in vogue in some of the leading medical schools of the United States. Since then, the course has been changed to conform to the requirements of the Association of American Medical Colleges. Mr. Painton, being poor in pocket, had to earn his own way. He *did teach a portion of each of two years.* In addition to the credits to which he was entitled, he took the summer courses, doing some work in both the medical and pharmacy departments, taking all the regular examinations in each portion of the work he pursued. In the medical department he took all the work required by the rules of the Association of American Medical Colleges, in addition to the credits which he might have claimed by reason of his studies previous to matriculating in medical college. He did this during the first two years of his course. The change in the course necessitated his taking the last two years' work at a time in the year which precluded his teaching. In these last two years he proved himself a good and intelligent student. He passed all his *examinations and received no conditions. All these facts* the college records show. Dr. Tait did not consult the records nor any member of the college faculty before writing his letter.

A word is necessary concerning catalogues. It is a well-known fact that a college catalogue is not an official record of either time of study or proficiency, but a mere list of the students matriculated by a college. This is true of all colleges. There is not a university or college catalogue on earth in which many faults might not be found. It is a mere announcement, and has no legal standing such as has the records of the college. Many students matriculate, and are catalogued, in every school in this country every year, who may not remain in school a month. That has nothing to do with the standing of the college or the proficiency of the student.

In view of all these facts, is it just to brand a respectable man as a fraud, because in the first place he is poor and has to earn his own way, and in the second place because he did his studying at one season of the year rather than another? Must a college be condemned because one individual finds fault with its catalogue, and that without any knowledge of the records of that college? Must a man be branded as a fraud because his work is ignored for the reason that it was done in the summer months rather than in the winter months? It is a gross injustice for one individual to accuse a man of fraud because his work was done in a different manner from that in which it is now done. The making of a law or a regulation of an examining board retroactive is contrary to the intent of any law or regulation. Nothing but a retroactive construction of the regulations of the state board could have denied to Mr. Painton the right to take his examination. Had he been admitted to the examination, there is no reason to doubt his ability to have passed the examination in a highly creditable manner. Ethan H. Smith.

Interstate Reciprocity in Medical Licensure.

Muncie, Ind., Sept. 13, 1906.

To the Editor:—Interstate reciprocity in medical licensure is of such importance to the medical profession that it should be well understood. Recognizing the excellent professional worth and influence of my good friend, Dr. E. B. Harvey, secretary of the Massachusetts Board of Registration in Medicine, and believing that he is in error in certain particulars in his discussion of reciprocity in The Journal, Aug. 25, 1906, I desire to discuss the same subject briefly.

The doctor admits that in the enactment of medical laws in the several states, the idea of protecting the people was made so prominent that the least benefit or convenience of the physician was not considered. For this reason and because under the constitution of the Union we can have no such thing as a national medical practice act, license under which would extend to the entire nation, thousands of good men are professional prisoners, each in his own state. For these men there are two sources of professional liberty: One is reciprocity between the states; the other is a re-test of qualification by examination in each state in which they desire to practice. The former plan is more practicable and equitable than the latter. When a man has once submitted to all the tests of qualification of his own state, and in doing so has submitted to the test of qualification required at that time in the states in which he may in future desire to practice, there is no good reason why he should be required to submit again and again to the inconveniences of re-examinations, provided satisfactory documentary evidence of the adequacy of the former test is furnished.

The doctor is all mixed up on the meaning of reciprocity. He sees the term, and hence the question, only in its political and commercial meaning. It has a broader meaning than he gives it. To reciprocate means: "To return an equivalent; to make a return in kind; to give and receive favors and benefits mutually."

Interstate reciprocity in medical licensure means, as now in practice under the rules of the American Confederation of Reciprocating, Examining and Licensing Medical Boards, an agreement by each state in the compact, to admit to medical licensure without re-examination, any licentiate of any other state, who has submitted to all the tests of qualification, required at the time of such test, by the state where the license is sought. The rules of the confederation, and such independent rules as each state may employ, are for the purpose of determining and making reasonably sure that each applicant is competent and worthy. Each state extending this courtesy to a sister state asks in return, and has a right to expect, a reciprocation of the courtesy. Reciprocity is not a requirement of the law in any state, but it is a discretionary privilege extended by the law to the state medical boards. If the law in any state does not permit this privilege, then that state can not have reciprocity and the law should be amended.

The proposition that "Reciprocity is impracticable unless it conserves the needs of society, and protects the community from charlatanisms," implies that if it does these, it is practicable. I hope to show that these are two of the things that it does accomplish.

When state boards are in proper reciprocal relation they are under agreement to aid each other reciprocally in preventing charlatans from skipping from one state to another for the purpose of deceiving and defrauding the afflicted. When the states are in proper reciprocal relation any board would be venal that would knowingly recommend to a sister state a scoundrel or an incompetent. The purpose of reciprocity and the actual effect among the 25 states now in the confederation, tends as a rule, to keep at home, where they are known, the professional vampires who have unfortunately obtained a legal right to practice, and to furnish professional liberty to the clean, competent men of the profession.

Reciprocity between states, according to the compact of the American Confederation of Reciprocating Boards, provides for just such reciprocal assistance and information as will enable a state board to mark the charlatan and to deny him recognition. The Ohio board does not know the charlatans of Indiana, but, Ohio and Indiana being in a reciprocity compact, Indiana furnishes Ohio information as to the moral and professional character of each man who desires to go from Indiana to Ohio on reciprocity, and Ohio reciprocates this favor. No state left to itself can as well protect itself as when it has the aid and coöperation of other states. Some medical vampires can pass a state board examination who could not get reciprocity and should not have it.

The doctor says that: "Reciprocity confers exclusive privileges on certain persons." In another paragraph he says that "reciprocity does not discriminate." Of course he could not be right in both statements. He is right, however, in one. Reciprocity does confer exclusive privileges on certain persons that are worthy and well qualified, and the vicious and incompetent are excluded.

Dr. Harvey says that under reciprocity in medical licensure "Maine would say to New Hampshire, we will permit your physicians to locate in Maine and will grant them a license without imposing any restrictions whatever as to their qualification, provided you will receive our physicians on the same conditions," and then knocks down this man of straw of his own production by calling it "free trade." This statement reveals the whole trouble with those who oppose reciprocity, namely: a complete misunderstanding of the basic requirements of reciprocity in medical licensure, which is uniform adequate qualification. No state board holding membership in the American Confederation of Reciprocating Boards would consider for a minute an applicant for reciprocal endorsement who could not establish his competency by incontestable evidence. The evidence must include the history of his preliminary and medical education; his moral and professional character, and his endorsement and recommendation by the board before which he furnished final test of qualification. If Dr. Harvey had known this, his Maine-New Hampshire illustration certainly would not have appeared in print. His hypothesis being wrong, his conclusions can not be right. The truth is that no two states under their laws could have such an agreement, nor hold membership in the confederation of reciprocating boards under such practice. Qualification is the chief corner-stone of medical reciprocity as set out in the constitution and by-laws of the American confederation and provided for by the several qualifications adopted by the confederation.

The statement that "reciprocity favors the admission into a state of high requirements, ignorant and incapable men from states of low requirements," is made in support of the proposition that "reciprocity deteriorates the standard of medical education." If this were true, then it would deteriorate the standard of medical education as contended, but the very reverse is true, because a state having high legal requirements admits, under reciprocity, only those who have submitted to like high requirements in the state from which they come. Neither a state nor individual is eligible to the privileges of reciprocity except by meeting the standard of the state whose license is sought. Hence all the advantages, privileges and benefits of reciprocity can be and are being used as incentives to bring up the standard of the states of low requirements. A reciprocity privilege is a badge of qualification, and hence of honor, and not to be despised by the profession.

Just here permit the suggestion that under the compact of the American Confederation of Reciprocating Boards, the rights of each individual board in each state are duly respected. Each board reserves the right to sit in judgment in the case of each applicant. Under this compact, a board in considering the rights of an applicant for registration by reciprocity can draw on the board of any sister state for information and facts relative to the applicant, and in no other way can so full information be obtained.

The argument is made that if reciprocity be adopted that unless all holding license in a state be admitted to equal privileges of reciprocity without regard to qualification, that it would be unconstitutional. This is erroneous, because reciprocity between the states, as provided for by law, is a discretionary privilege, extended to the state boards, and not a mandatory requirement; besides, the exclusion of the incompetent and vicious, and the admission of the competent and worthy by a reciprocity agreement between the states, is not "class legislation," as contended, no more than the same would be when done by state legislature, and none question the right of the legislature to exclude the incompetent.

The contention that reciprocity would be inequitable because some state boards are too lenient in the examination of applicants as shown by the small per cent. of failures, while others scrupulously perform their full duty as evidenced by the large number of failures, should be considered in the light of all the facts. It must be remembered that under the laws in some states the boards are required to examine all applicants, regardless of previous preparation or qualification. An applicant must be examined regardless of the kind of college in which he has studied, or even if he has attended no college. He may be a graduate or he may not. He may never have seen a medical college; he may know nothing of medicine. Of course, a large per cent. of this class of undergraduates would fail. In other states, as in Indiana, only graduates of good colleges; men who have studied medicine four full years, and passed a satisfactory examination before a competent faculty and graduated; having previously acquired adequate preliminary education, are eligible to examination before the state boards. Of this class of high-grade graduates in medicine a smaller per cent. will fail. Again, it should not be forgotten that an examining board, under certain conditions, may be unjustly exacting.

On the hypothesis, however, that an evil does exist, I ask how is it to be corrected? Can it be done by leaving the boards to themselves? Or can it be sooner remedied by a reciprocity compact between the boards whereby the influence of all the states can be employed in demanding and assisting in its correction? Neither the state medical examining board nor the profession in any state will long submit to the odium of exclusion from rights and privileges because of inferiority of the law, or dereliction of duty by the board. Hence, reciprocity, with the light of publicity attending it, is the best possible remedy for an evil of this kind. No American physician should be satisfied because some states have reached a high standard of medical education, but should strive to bring all to the same high plane.

Under the rules of reciprocity, as now established and practiced, a state board can not only ask for the certified facts as to the registration of an applicant in the state from which he comes, but can demand the evidence of his qualification as given in his test before the state board where his primary registration occurred, including his examination papers. Hence, under reciprocity each state board must show its hand.

This fact kills Dr. Harvey's illustration of the young man who, following the line of least resistance, takes his examination in an easy state, and then attempts to go by reciprocity into one of more stringent requirements. The light of publicity is the best remedy for an evil. Reciprocity furnishes publicity and turns on the light, and tends to secure uniformity in medical education, legislation and administration.

If the New York wife seeking divorce in the Dakotas were compelled to take with her certified evidence from the New York courts with a recommendation from the New York authorities that the divorce be granted, in order to secure the decree of divorce in Dakota, she would probably stay at home and behave herself, as the quack must do under reciprocity.

The argument is submitted that reciprocity is of "limited usefulness." So is everything else. All men would not need the advantage of reciprocity, and there are some men in every state who could not get it, but deserving men who want reciprocity, and are entitled to it, should not be deprived of it on this account. Reciprocity can not be general and universal, in the sense of including states that do not furnish adequate tests of competency, or individuals that are unworthy or incompetent.

During the last few years more than 1,000 excellent men, representing a majority of the states of the Union, have obtained reciprocity in medical licensure, showing that reciprocity has at least a degree of practicability.

As a substitute for reciprocity, it is contended that the several state boards should be given "discretionary powers," to be exercised in the interest of "experienced and notable men of the profession." The reciprocity provision in the medical laws gives discretionary power; not, however, to be used arbitrarily in the interest of "experienced and notable men in the profession," but to be used in accordance with fixed and definite principles and rules of equity agreed on by all the states in the compact, so that uniformity may obtain and that all competent and worthy men may be treated alike, whether "notable" or not. Hundreds of the best men of the profession are quiet and unobtrusive, not known outside their own state, but can furnish incontestable proof of splendid competency. Reciprocity takes care of these men as effectually as it does of the "experienced and notable men of the profession," such as "professors and teachers in the medical colleges."

Again, it is claimed that reciprocity is in violation of the doctrine of "state sovereignty" and, hence, impracticable. It is difficult to understand just what is meant by this, or how state sovereignty could prevent a state from exercising its legitimate rights. One would think that a believer in state sovereignty would not question the right of a state to establish the necessary rules for the reciprocal recognition of the official acts of other states. To talk about state sovereignty, and then turn about and say that the states have not the right to make a reciprocity agreement, is inconsistent. State sovereignty, if it means anything, means the right of the state to do anything in the interest of its people which does not conflict with the organic law of the nation, nor abridge the rights of the people of other states. State sovereignty favors reciprocity between the states if it has anything to do with it at all. W. A. Spurgeon,

President of the American Confederation of Reciprocating, Examining and Licensing Medical Boards.

State Board Results in the Educational Number.

Springfield, Ill., Sept. 17, 1906.

To the Editor:—Please allow me space to dwell further on the erroneous conceptions which may be gained by the casual reader through a misinterpretation of the significance of the data in the Educational Number of The Journal, August 25.

I have now before me a printed postal card which I believe has been sent broadcast, bearing the bold-faced caption, "Failures of Chicago Graduates," and giving a list of the different medical colleges of Chicago with the percentages of failures of their students before the "different state medical examining boards throughout the United States during the year 1905." The Journal, Aug. 25, 1906, is quoted as the authority for the figures.

This card shows the National Medical University as the Chicago medical college established over five years having the smallest percentage of failures, with the Northwestern University Medical School and Rush Medical College in the second and third place, respectively. The reader, conversant with the standing of the two older colleges among the medical institutions of the state, is at first skeptical, but on referring to your Educational Number (Table A) he finds that the author of this card is fully supported by your figures, and was guilty of no misrepresentation when he quoted The Journal as his authority.

This incident illustrates forcefully the danger of the publication of deductions drawn from data whose figures are not uniform in significance. To the vast majority of the readers of The Journal to whose attention this card may come, the statements on the card are fully substantiated by reference to your Table A, and they will not take the trouble to go further to ascertain the exact facts. We have here, in short, a very widely promulgated misconception, for which The Journal is unfortunately made to stand sponsor.

It is true, as you have said, that your readers were cautioned, in the editorial accompanying these data, to consider the conditions surrounding their origin, but it is my impression that a very large percentage of those who glanced over the deductions of your tables paid little or no attention to their discussion and explanation. The average reader is prone to accept conclusions, especially when based on figures, with little concern as to their source.

On an analysis of your figures we find that the National Medical University, the school credited with the highest standing, had 24 applicants who appeared before but 7 examining boards. One of these applicants failed to pass an examination. Northwestern University Medical School had 191 applicants before 27 boards, and 10 of these failed to pass an examination. Rush Medical College had 254 applicants before 30 boards, and 21 failed to pass an examination.

Of the failures of Northwestern 6 were before boards which rejected from 25 to 50 per cent. of all applicants from other states. Of the failures of Rush Medical College 10 were before boards rejecting 25 per cent. or more of applicants from other states. The National had but 1 gradute before any board which rejected more than 25 per cent. of applicants, and that one failed.

As I said in my communication in THE JOURNAL, September 15, "we might as well eliminate from our data the showings of colleges whose graduates have appeared before only a small number of boards, as these showings indicate little as to the ability of the graduates of such schools to pass the average state board examination."

It is obvious that percentages drawn from the successes and failures of the National Medical University and the other two institutions are in no way comparable. I am not prepared to say what success the graduates of the school given highest place would have attained before a larger number of boards, but for 1905 the percentage is based on results before an insufficient number to give an adequate idea of the standing of any school. Still THE JOURNAL, through the publication of these deductions and percentages, is compelled to stand sponsor for statements which are very widely promulgated and used to influence the young men of the country in the selection of the place for their medical education.

JAMES A. EGAN,
Secretary, Illinois State Board of Health.

EDITOR'S NOTE: Our correspondent refers to a postal card which, although anonymous, leaves little doubt as to its source. It is to be noted how skilfully its author, by the use of the words "colleges established five years or more," omitted one college, an evening school, which happens to have a still lower percentage, by reason of having had only one graduate examined outside of Illinois and he failing. A college that had received, in an exceptional year, and often from a combination of circumstances, an unusually low percentage of failures could hardly be blamed for taking advantage of it, since another opportunity might never occur. That it should send out anonymous statements, for the purpose of conveying a wrong impression, as the cards referred to doubtless were sent out, only adds to the suspicion with which at least one Chicago college is regarded. This suspicion our correspondent seems to share. If the suspicion is not well founded, why is it not as fair for one college to be shown up as having received a low percentage as another? As to the figures being insufficient, the college had 29 graduates, 24 of whom took the examination. This would seem to be a large enough proportion for a fair basis for figuring the percentage.

The statistics published are uniform except in degree in which they never could be uniform, and therefore could never be strictly "uniform in significance." Because a casual reader may form a wrong conclusion or because a college so inclined may publish half-truths for selfish purposes, are not good reasons for withholding from publication statistics which are of absolute value to the careful reader.

While there are bound to be differences between the percentages of the same college from year to year, each year hereafter will furnish larger totals from which to make deductions and then the deductions, of course, will have added value. For the past three years the figures for Chicago colleges are as shown in the accompanying table. It will be noted that the college which appears first on the anonymous postal card takes a back seat at this table.

TABLE SHOWING RESULTS OBTAINED BY GRADUATES OF CHICAGO COLLEGES IN EXAMINATIONS BY STATE EXAMINING BOARDS HELD DURING THE YEARS 1903, 1904 AND 1905.

PROBLEMS IN ANIMAL METABOLISM. A Course of Lectures Given in the Physiological Laboratory of the London University at South Kensington in the Summer Term, 1904. By J. B. Leathes, Lecturer on Physiology in the Medical School of St. Thomas's Hospital. Cloth. Pp. 205. Price, $2.00. Philadelphia: P. Blakiston's Son & Co., 1906.

If one may judge by the activities of writers and publishers, our English colleagues appreciate—somewhat better than we seem to do—the importance of recent progress in biologic chemistry for the solution of medical problems. Recently we reviewed in these columns two books written with the object of rendering these advances accessible to medical readers; namely, Mann's "Chemistry of the Proteids," and Hill's "Recent Advances in Physiology and Biochemistry." Of similar purport is this book by Leathes, which is based on a course of lectures given in the physiologic laboratory of London University with the object of presenting to medical students in correlated form the results of recent studies in biologic chemistry, in so far as they apply to human physiology and to medicine. An introductory chapter discusses briefly the modern theories and discoveries concerning the chemistry of the proteids and other constituents of the animal body, as well as the essential features of enzyme action. The metabolism of carbohydrates, fats and proteids is then considered, together with a separate chapter on the metabolism of cyclic compounds. Included in these chapters are brief discussions of the metabolic abnormalities, such as glycosuria, pentosuria, alkapton uria, cystinuria, acetonuria, etc. As this book is based on a series of lectures given for the purpose of popularizing an intricate subject the material has been handled with the object of emphasizing principles rather than of exhaustively considering all of the known facts. The author has succeeded well in accomplishing this purpose, and the physician who desires to familiarize himself with the progress in the fundamental principles of animal metabolism will find in this book an attractive and concise discussion of the subject. One is impressed with the excellent selection of illustrative examples used by the author in explaining various theories and hypotheses. On the other hand, a tendency to form exceedingly involved sentences robs these essays of much of that clearness which is so essential to a successful popularization of technical topics, and partially offsets the admirable selection of the subject matter.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. Whitthaus, A.M., M.D., Professor of Chemistry, Physics and Toxicology at Cornell University, and Tracy C. Becker, A.B., LL.B., Counsellor at Law, Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. Second edition. Pp. 99 Price, $6.00. New York. Cloth. William Wood & Co., 1906.

In this volume are considered the various topics of pure medical jurisprudence. The legal relations of physicians and surgeons to their patients, as witnesses and in suits for malpractice, with a synopsis of the laws of the various states on these subjects, form the section on medical jurisprudence proper. This is followed by the thanatologic division of forensic medicine, including the legal status of the dead body, the powers and duties of coroners, autopsies, personal identity, the time of death, and the action of heat, cold and starvation. Numerous cases are cited illustrating the various subjects.

Marriages

August H. Gorenflo, M.D., to Miss Hattie Clippert, both of Detroit, September 12.

John W. Hoffman, M.D., to Miss Edna MacPherson, both of Detroit, September 26.

George C. Wallace, M.D., to Mrs. Jane B. Odell, both of Detroit, September 15.

Marion T. Benson, M.D., to Miss Sallie May Bagley, both of Atlanta, Ga., September 12.

Henry Adsit, M.D., Hornell, N. Y., to Miss Peachy P. Brown, at Baltimore, September 15.

J. Henry Dowd, M.D., to Miss Louise Lyman, both of Buffalo, N. Y., September 17.

Clarence L. Six, M.D., to Miss Genevieve Peters, both of Stockton, Cal., September 3.

John L. Halliday, M.D., to Miss Tacy Graff, both of Wellington, Kan., September 22.

Homer L. D. Jenkins, M.D., Hughes Springs, Tex., to Miss Ella B. Keasler, September 2.

Edgar D. Rush, M.D., Celina, Ohio, to Miss Eva Morton, of Fletcher, Ohio, September 10.

Lewis Clyde Bixler, M.D., Pittsburg, to Miss Ida Evans, of Easton, Pa., September 19.

Ralph A. Dalbey, M.D., Youngstown, Ohio, to Miss Centell, of Philadelphia, September 19.

Paul Guilford, M.D., to Miss Ethel Margaret Hamline, both of Chicago, September 19.

Robert S. McCombs, M.D., Philadelphia, to Miss Richenda Pratt, of Carlisle, Pa., September 8.

Samuel L. Adair, Jr., M.D., to Miss Grace Ethel Thompson, both of New Washington, Ind., September 15.

Stanley A. E. Brallier, M.D., Conemaugh, Pa., to Miss Emma Hillock, of Philadelphia, recently.

William Cammack, M.D., Salem, Iowa, to Libbie Seymour, M.D., of Iowa City, Iowa, September 12.

Joseph G. Mahoney, M.D., Shelton, Conn., to Miss M. C. Fahy, of New Haven, Conn., September 6.

Irving Wagoner Metz, M.D., Springfield, Ill., to Miss Edith Mabel Thorp, of Havana, Ill., September 26.

Francis Le Roy Satterlee, M.D., to Miss Mary Philipse Iselin, both of New York City, September 19.

Clarence J. Whalen, M.D., Wellsville, N. Y., to Miss Lena Loughley, of Coudersport, N. Y., September 11.

Simon F. Earnest, M.D., Philadelphia, to Miss Emma J. Meily, of Deodate, Pa., at Annville, Pa., September 7.

James H. Hartwell, M.D., to Miss Mary Lewis Dicksin, both of Stewartsville, Va., at Roanoke, Va., September 15.

Albert J. Underhill, M.D., Baltimore, to Miss Carrie Robb, Brown, on Miles River, near Royal Oak, Md., September 15.

Benjamin C. Stevens, M.D., Logansport, Ind., to Miss Alice Mertz, of Burnettsville, Ind., at Riverside, Ill., September 18.

A. C. Wollenberg, assistant surgeon, U.S.P.H.&M.-H. Service, to Miss Florence Zoe Allen, of Detroit, September 22.

Lieutenant Frank Thomas Woodbury, assistant surgeon U.S. Army, to Mrs. Caroline Townsend Fremont, at Manila, P. I., September 12.

Deaths

Philip Skinner Wales, M.D. University of Maryland School of Medicine, Baltimore, 1856; captain and medical director, United States Navy, retired; surgeon general of the Navy from 1879 to 1884; who entered the service, Aug. 7, 1856, and attained his present grade Oct. 15, 1881, serving eight years and five months at sea and twenty-one years and two months on shore duty, and was retired Feb. 27, 1896, died suddenly from cancer of the intestines in the Hotel de St. James et d'Albany, Paris, September 15. His body will be embalmed and brought to Annapolis, Md., for burial.

Henry H. Ruger, M.D. Jefferson Medical College, Philadelphia, 1865; a pioneer citizen of Devil's Lake, N. D., who served from 1876 to 1882 at Fort Abercrombie, Fort Totten, various Missouri River posts and in a number of military expeditions against the Indians west of the Missouri; county commissioner of Ramsey County for many years; representative in the Territorial Assembly in 1885; examining surgeon of the pension department and health officer of Ramsey County, died at his home in Devil's Lake, September 12, aged 67.

Walter C. Jackson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1852, who played a prominent part during the yellow-fever epidemic in Montgomery, Ala., in 1853, and was a resident of that city until his death; once president of the city board of health and for several terms a member of the common council; one of the oldest and best-known practitioners of Montgomery, died at his home in that city, September 20, after an illness of three days, aged 79.

Henry Halbert Deming, M.D. Chicago Medical College, 1868; a member of the American Medical Association, Illinois State Medical Society and Chicago Medical Society; one of the founders and at one time president of the Chicago Hospital; formerly a practitioner of Pana, Ill., but for a number of years a well known and esteemed physician of Chicago, residing on the South Side, died suddenly while making a professional call, September 22, from angina pectoris, aged 61.

J. R. Anders, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1904, who went to Central American ports last winter as representative of the Mississippi Board of Health, with the party of southern health officials to study sanitary and quarantine conditions, and who was in charge of Rosetta during the yellow-fever epidemic last year, died at his home in Gloster, Miss., September 15, from typhoid fever, after an illness of several weeks.

Sherman T. Brown, M.D. Gross Medical College, Denver, Colo., 1897; a member of the American Medical Association; demonstrator in anatomy in Gross Medical College and one of the most prominent young surgeons of Denver, was taken ill with appendicitis while performing an appendicectomy in Mercy Hospital, and died in that institution Sepetmebr 15, three days after operation, from postoperative pneumonia, aged 32.

William Henry Lilly, M.D. New York University, New York City, 1860; assistant surgeon and later surgeon of the Fifty-second North Carolina Infantry, C.S.A., in the Civil War; a member and once vice-president of the Medical Society of the State of North Carolina; for 37 years a resident of Concord, N. C., and one of its most prominent physicians, died at his home in that city, September 12, after an invalidism of about a year, aged 72.

Evander J. Goodsell, M.D. Cleveland Medical College, Medical Department of Western Reserve College, 1880; a member of the American Medical Association and one of the oldest and best-known practitioners of Norwalk, Ohio, died at Lakeside Hospital, Cleveland, September 19, a short time after an operation for gangrenous appendicitis and intestinal obstruction.

George F. Lightfoot, M.D., New York Homeopathic Medical College and Hospital, New York City, 1891; formerly a member of the board of health and health officer of Kearney, N. J.; a practitioner of Arlington, N. J., died in St. Michael's Hospital, Newark, N. J., September 17, from kidney disease, after an illness of several years, aged 41.

Leonard Darling White, M.D. Harvard University Medical School, Boston, 1883; for many years a member of the board of health of Uxbridge, Mass., and for the last 10 years assistant medical examiner; a member of the Thurber Medical Society of Milford, died suddenly at his home in Uxbridge, September 18, from heart disease, aged 47.

boards rejecting 25 per cent. or more of applicants from other states. The National had but 1 gradute before any board which rejected more than 25 per cent. of applicants, and that one failed.

As I said in my communication in The Journal, September 15, "we might as well eliminate from our data the showings of colleges whose graduates have appeared before only a small number of boards, as these showings indicate little as to the ability of the graduates of such schools to pass the average state board examination."

It is obvious that percentages drawn from the successes and failures of the National Medical University and the other two institutions are in no way comparable. I am not prepared to say what success the graduates of the school given highest place would have attained before a larger number of boards, but for 1905 the percentage is based on results before an insufficient number to give an adequate idea of the standing of any school. Editor's Note: Our ... whic' 74.

Edwin B. Payne (Years of Practice, N. D.); a veteran of the Civil War; the first physician of McHenry County, and for 12 years coroner of that county, died at his home in Towner, N. D., August 15, from dropsy, after an illness of six months, aged 62.

Arthur Knight, M.D. Eclectic Medical Institute, Cincinnati, 1876; a veteran of the Civil War, and since then a practitioner of Sauquoit, N. Y., died at his home, September 16, from cerebral hemorrhage, after an illness of more than two years aged 65.

Thomas J. Williams, M.D. Rush Medical College, Chicago, 1893; interne in Cook County Hospital in 1894 and 1895; physician of Leadville and of Lake County, Colo., shot and killed himself in his office in Leadville, September 19, aged 43.

William M. Oates, M.D. College of Physicians and Surgeons, Baltimore, Md., 1894, health officer of Bridgeport, Ohio, died at the North Wheeling (W. Va.) Hospital, September 18, from typhoid fever, after an illness of two weeks, aged 34.

James F. Munn, M.D. College of Medicine, Syracuse (N. Y.) University, 1881, for 25 years a practitioner of Syracuse, died September 16, at the Hospital of the Good Shepherd in that city, from uremia, after a long illness, aged 55.

Joseph Lyle Thornton, M.D. Medical College of Ohio, Cincinnati, 1862, a pioneer educator of Ohio, died at his country home, near Middletown, Ohio, August 17, from arteriosclerosis, after an illness of six months, aged 79.

Dennis J. McCabe, M.D. New York University, New York City, 1898, was thrown from his carriage in a runaway accident near his home in Berlin, N. H., September 16, and died three-quarters of an hour later.

John S. McNaught, M.D. College of Physicians and Surgeons in the City of New York, 1846; a prominent and esteemed practitioner of Hobart, N. Y., died at his home in that city, September 8, aged 87.

William A. Dole, M.D. Jefferson Medical College, Philadelphia, 1901, a practitioner of Lyndon, Kan., for five years, was killed in a runaway accident two miles southeast of Lyndon, September 16.

George M. Reed, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1869, died at his home in Massillon, Ohio, September 8, after a lingering illness, aged 58.

Edward A. Wheeler, M.D. Bellevue Hospital Medical College, New York City, 1879, a member of the Kings County Medical Society, died suddenly at his home in Brooklyn, September 19, aged 55.

Levi J. Enders, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1876, died at his home in Williamstown, Pa., after a short illness, September 11, aged 52.

Blake Bigelow, M.D. University of Vermont, Medical Department, Burlington, 1883, of St. Regis Falls, N. Y., died in a hospital in Boston, September 13, from nephritis, aged 45.

While ..n S. Bachman, M.D. Long Island College Hospital, ages of /n, 1870, for many years a practitioner of Easton, Pa., after wt his home in Philadelphia, September 10, aged 69.

and ..tron V. Talbert, M.D. Cincinnati Medical College, 1846, the d at his home in Pasadena, Cal., July 4, from carcinoma of shoe stomach, after an illness of six weeks, aged 80.

Daniel Henry Brown, M.D. Medical College, of Indiana, Indianapolis, 1900, a colored physician of Indianapolis, died at his home in that city, September 19, aged 32.

Guy M. Brothers, M.D. Medical College of Indiana, Indianapolis, 1904, committed suicide at his home in New Paris, Ind., by taking cocain, September 19, aged 33.

Harvey R. Benham, M.D. Eclectic Medical Institute, Cincinnati, 1853, died at his home in Richmond, Ind., September 15, from senile debility, aged 83.

David H. Crisp, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1846, died at his home in Uvalde, Texas, June 25.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

A SENSITIVE TEST FOR ALBUMIN.

Paducah, Ky., Sept. 14, 1906.

To the Editor:—In Volume XLVII No. 10, pp. 816 of The Journal, there is an excerpt from an article by Tognetti in the *Gazetta degli Ospedali*, Milan, describing a sensitive test for albumin. I want to know how long he allows the specimen to stand before deciding. He says "gradually throws down in a yellowish-white precipitate." Harry A. Smith.

Answer.—In addition to the description on page 816 we quote from the author as follows: "If there is no albumin in the urine, the opaque appearance, produced by the addition of the tanno-alcohol mixture and heating, vanishes as the hydrochloric acid is added. If, on the other hand, there is albumin in the urine, the opaque appearance persists even after the hydrochloric acid has been added, and in the course of about a quarter of an hour a yellowish white precipitate accumulates in the bottom of the test-tube."

COLEY'S SERUM FOR INOPERABLE SARCOMA.

——, Mich., Sept. 18, 1906.

To the Editor:—Please inform me through The Journal what Coley's serum for inoperable sarcoma consists of and how and where it can be secured? Do you know anything about its success? S.

Answer.—Coley's serum is a mixture of toxins obtained by cultivating the germs of erysipelas for three weeks in cacao broth, inoculating this culture with *Bacillus prodigiosus*, and cultivating for four weeks longer. The mixture is then sterilized at 136° F. and the liquid used for hypodermic injection. The dose is 1 to 8 minims, beginning with a small dose and gradually increasing. The injections may be followed by high fever and the method is not entirely free from danger. A few persons have been reported as apparently cured by this method and some regard it with favor for postoperative treatment to prevent recurrence. The general opinion, however, seems to be that the treatment should be applied only to inoperable cases, and then must be regarded merely as an experiment. The serum is listed in the catalogue of Parke, Davis & Co., but we do not find it in that of any other firm.

HOW TO SUBSCRIBE TO FRENCH MEDICAL JOURNALS.

San Angelo, Texas, ——.

To the Editor:—1. Please inform me as to the subscription price of the following French journals and the addresses of the subscription agencies to which the money must be sent: *Bulletin de l'Académie de Médecine, Presse Médicale, Semaine Médicale.* O. H. Johnson.

Answer.—*Bulletin de l'Académie de Médicine;* publishers, Masson et Cie, 120 Boulevard Saint Germain, Paris, France. Subscription price, 20 francs, which is approximately $4.00 in United States currency and includes postage.

The *Presse Médicale* is a bi-weekly journal; publishers, Masson et Cie, 120 Boulevard Saint Germain, Paris, France. Subscription price 15 francs, which is approximately $3.00 in United States currency, and includes postage.

Semaine Médicale, edited and published by Dr. de Maurans, 53 avenue de Villiers, Paris, France. Subscription price, 10 fran of which is approximately $2.00 in United States currency, and cludes postage.

A very convenient way of sending the money is by a postoffic money order made payable to the publisher of the journal.

METHOD OF FUMIGATING WITH FORMALDEHYD.

Mankato, Minn., Sept. 13, 1906.

To the Editor:—Kindly give me the method of fumigating by formaldehyd by using permanganate of potash. I have heard much of the method and have consulted many authorities without success, so I take the liberty of asking you.

John M. Edwards.

Wardsville, Ont., Can., Sept. 23, 1906.

To the Editor:—What is the cheapest and best chemical method of liberating formaldehyd gas for fumigating purposes? Is it considered as good as using one of the generators now on the market?

W. H. Rennie, M.D.

Answer.—These questions were answered in The Journal, July 14, 1906, page 139. A discussion on the relative amounts of the ingredients, consisting of letters from representatives of the state boards of health of Iowa and Illinois, will be found in The Journal July 28, page 288, and August 18, page 523. A further note on an experimental comparison of methods was printed September 22, page 952.

ALCOHOLIC STRENGTH OF COCAIN HYPODERMIC SOLUTIONS.

Fisherville, Ont., Can., Sept. 18, 1906.

To the Editor:—What proportion of alcohol (98 per cent. strength) should be added to a cocain or eucain B. solution for injection in the gums for tooth extraction in order to preserve the solution thoroughly? What would be the greatest alcoholic strength of a solution that could be used for hypodermic purposes that would not prove dangerously irritating or annoying?

M. D. Baker.

Answer.—Alcohol in 10 per cent. solution will inhibit the growth of bacteria, according to W. H. Park ("Bacteriology in Medicine and Surgery"). Bartholow states that alcohol may be used hypodermically in the dilute form as whisky or brandy ("Materia Medica and Therapeutics," 10th edition). H. C. Wood ("Hare's System of Practical Therapeutics," 2d edition) says that 10 minims of tincture of digitalis (made with diluted alcohol) can be injected without causing serious local trouble. It is probable, therefore, that from 40 to 50 per cent. of alcohol could be used for hypodermic purposes without irritating. If properly made, solutions of cocain keep for some time without addition of an antiseptic. Probably chloroform water as a vehicle or phenol (1 minim of a 5 per cent. solution to 4 ounces) as used in the Schleich method, would be preferable to alcohol. It is preferable not to try to keep solutions of these substances long, but to make them fresh when needed.

CONTINUOUS WATER BATHS FOR BURNS.

New York, Sept. 10, 1906.

To the Editor:—In The Journal, September 8, in your answer to Dr. Burr's inquiry you speak of the disuse of the method for treating burns, which is attributed to Hebra. Permit me to state that the method has by no means been abandoned; on the contrary, it is still appreciated as the ideal one in extensive burns, only the American colleagues are not familiar with it. As the matter merits attention, I wish to give a few notes of historical studies which I have collected on the continuous bath in extensive burns.

Sept. 14, 1857, a fire broke out in the pyrotechnical laboratory in Frankfort on the Main. Of twenty persons burnt, seven had perished in the flames or died from inhaling obnoxious gases. Among the thirteen remaining who were taken to the hospital different degrees of combustion presented themselves. All these cases were treated by Dr. G. Passavant and all except those with burns on the head alone were given the continuous warm bath, according to the extent of the injury—the partial or the full bath. This is the first record I can find in literature of treatment of burns by the continuous warm water bath.

We see Passavant has treated extensive burns with the continuous bath in the year 1857 (his first publication of the method appeared in the year 1858), but Hebra writes in the *Allgemeine Wiener Medizinische Zeitung*, 1861, No. 43: "The continuous full bath given for therapeutic purposes and kept up for days, weeks and months has, as far as I am aware, never been tried or carried out by any one." He says he has made use of this method in three cases during the year 1860. His experience in the treatment of such injuries by means of ointments and caustics had been most unsatisfactory, and these sad experiences gave him the idea to make use of the continuous warm bath in case of extensive burns.' He does not mention Passavant, whose article appeared in the best known German medical journal of that period, namely, the *Deutsche*

Deaths

Philip Skinner Wales, M.D. University of Maryland School of Medicine, Baltimore, 1856; captain and medical director, United States Navy, retired; surgeon general of the Navy from 1879 to 1884; who entered the service, Aug. 7, 1856, and attained his present grade Oct. 15, 1881, serving eight years and five months at sea and twenty-one years and two months on shore duty, and was retired Feb. 27, 1896, died suddenly from cancer of the intestines in the Hotel de St. James et wa l'Albany, Paris, September 15. His body will be embalmed
buri brought to Annapolis, Md., for burial.

Langenbeck, who in the year 1850, introduced continuous immersion as a method of treating surgical wounds, characterized it as the mildest method, not requiring dressing, securing clean wounds in a way which could not be surpassed by any other method.

Concerning further and most essential advantages of the continuous warm bath in case of burns we have to study the physiologic action of the warm bath on circulation and innervation in general. I may be permitted to refer to the chapter on the continuous warm bath in my book, "Carbonic Acid in Medicine." Here I will only call attention to a few points. Since we, thanks to recent investigations, know more of the physiologic effect of the warm bath on circulation and innervation, we can explain better its importance, especially in severe burns. There are certainly many cases which would prove fatal without the advantage of this means, while with the aid of the continuous warm bath they make a good recovery. We know the serious effect of extensive burns on the nervous system, and here the continuous warm bath must be considered as the best of all remedies.

When a part of the body is placed in warm water, the nerve ends of the skin become irritated. This irritation is transmitted to the vasomotor nerves and is followed by dilatation of the blood vessels, and consequently by acceleration of the circulation. This accelerated blood circulation facilitates the elimination of the products of inflammation and infection, and with the removal of pyrogen substances and toxins through the general circulation, fever will be reduced. The warm baths are a means to stimulate metabolism, the principal desideratum when we have to deal with severe injuries needing great recuperative power. In a more elaborate paper I am preparing I intend to deal more fully with these points, and also to give the most interesting history of the therapeutic use of the continuous bath. Here only a few notes: Research in the history of the continuous bath as a therapeutic measure shows that its introduction has been ascribed to two German surgeons, Fritz and von Walther, who lived during the latter part of the eighteenth and the first quarter of the nineteenth centuries; others ascribe it to Baudelocque, the great obstetrician of the time of Napoleon I. Baudelocque made use of it in peritonitis. His method was revived by Noeggerath in the German Hospital of New York, but abandoned again after Noeggerath's departure.

The first who used the continuous bath in surgery seems to have been Paulus of Ægina, who lived in the seventh century under the reign of Heraclius, the Byzantine emperor. Paulus had patients, operated on for hernia, especially children, submersed in warm water for seven consecutive days in order to prevent inflammatory symptoms.

All these early advocates of the continuous bath, beginning with Paulus of Ægina, and later on Stromeyer and Langenbeck, in the explanation of the effects of the continuous bath pronounced—although they did not say the name—antiseptic principles. All who have had experience with it will confess that it is still the most reliable antiseptic in extensive burns.

The continuous bath in therapeutics has not been appreciated as it should have been by American physicians. Dr. Dent, whose death we have reason to lament, was the first to introduce it in this country in the treatment of insane.

A. Rose.

Frank W. Selman, M.D. Medical College of Indiana, Indianapolis, 1903; assistant surgeon Third Infantry, Ind.N.G.;
secretary of the board of health of Greenfield, Ind., and a mem-
ber of the Hancock County Medical Association, died suddenly
at his home in Greenfield, September 11, from cerebral hemor-
rhage, aged 25.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, week ending Sept. 22, 1906:

Moore, J. M. surgeon, detached from *Franklin* and to *Newark*.

Bogan, F. M., P. A. surgeon, detached from *Marietta* and to New York Hospital for treatment.

Brown, J. L., asst.-surgeon, to duty with Recruiting Party No. 3.

Richardson, F. A., acting asst.-surgeon, home and await orders.

Iden, J. H., P. A. surgeon, to *Newark*.

Hoyt, R. E., P. A. surgeon, to Naval Academy, Annapolis, Md.

Asst.-Surgeons, W. E. Schaller, I. F. Cohen, J. B. Kaufman, M. H. Ames, T. W. Raison, J. M. Minter, J. Flint, A. H. Allen, P. E. Garrison, J. O. Downey, A. H. Robnett, R. C. Ransdell, W. S. Kuder, J. P. Haynes, H. Butts, C. K. Winn, A. McK. Jones and H. L. Smith and Acting Asst.-Surgeons R. I. Longabaugh, W. G. Steadman, H. L. Dollard, E. P. Huff, M. C. Baker, F. D. Chappelear and E. E. Curtis to Naval Medical School, Washington.

Norton, O. D., surgeon, detached from *Yankee* and to *Missouri*.

R. M. Kennedy, surgeon, detached from *Missouri*, and to Bureau of Medicine and Surgery.

Wm. Seaman, P. A. surgeon, detached from Boston yard and to *Prairie*.

Murphy, J. F., P. A. surgeon, from Omaha Recruiting Office to *Georgia*.

W. H. Bell, surgeon, and Asst.-Surgeon J. P. DeBruler, report to Surgeon General, special duty.

C. C. Grieve, asst.-surgeon, to Omaha Navy Recruiting Office.

Dean, F. W. S., asst.-surgeon, to New York Navy Yard.

Dykes, J. R., asst.-surgeon, from New York Navy Yard to New Orleans Naval Station.

Block, W. H., acting asst.-surgeon, from New Orleans Naval Station to Navy Recruiting Party No. 4.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending September 19, 1906:

Stoner, G. W., surgeon, granted four days' leave of absence from September 8, under the provisions of Paragraph 189 of the Regulations.

Clark, Taliaferro, P. A. surgeon, granted leave of absence for two months from September 15.

Billings, W. C., P. A. surgeon, relieved from duty on the U. S. S. *Rush*, and directed to proceed to Vancouver, B. C., for duty in connection with the examination of aliens.

Korn, W. A., P. A. surgeon, relieved from duty at Perth Amboy, N. J., and directed to proceed to Reedy Island Quarantine Station and assume command of the service at that port.

Holt, J. M., P. A. surgeon, relieved from duty at San Francisco and directed to proceed to Columbia River Quarantine Station, Astoria, Ore., assuming command of the service at that port.

Glover, M. W., P. A. surgeon, relieved from duty at Vancouver, B. C., and directed to proceed to Sitka, Alaska, for duty on the U. S. S. *Rush*, relieving P. A. Surgeon W. C. Billings.

McCoy, G. W., P. A. surgeon, granted leave of absence for two months from October 4.

Smith, F. C., asst.-surgeon, relieved from duty at Detroit, and directed to proceed to Perth Amboy Quarantine Station, N. J., and assume command of the service at that port.

Ashford, F. A., asst.-surgeon, directed to proceed from Ellis Island, N. Y., to Philadelphia, for temporary duty.

McKeon, F. H., asst.-surgeon, relieved from temporary duty at Columbia River Quarantine Station and directed to proceed to San Francisco for duty and assignment to quarters.

Miller, W. W., asst.-surgeon, directed to proceed to Ellis Island, N. Y., reporting to the Medical Officer in command for duty.

allenberg, R. A. C., asst.-surgeon, directed to report to the
dical officer in command at Detroit, for duty and assignment to
Barters.
dBean, L. C., acting asst.-surgeon, granted leave of absence fo
ght days from September 11.

Nute, A. J., acting asst.-surgeon, granted leave of absence for seventeen days from September 25.

Allen, G. C., pharmacist, granted leave of absence for two months, from September 28, 1906, without pay.

Van Ness, G. I., Jr., pharmacist, directed to report to Surgeon P. M. Carrington, chairman of board of examiners, to determine his fitness for promotion to the grade of pharmacist of the second class.

BOARD CONVENED.

A board was convened to meet at Fort Stanton, N. M., on the call of the chairman, for the examination of Pharmacist G. I. Van Ness, Jr., to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the Board: Surgeon P. M. Carrington, chairman; P. A. surgeon L. D. Fricks, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 21, 1906:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, Sept. 1-8, 4 cases, 1 death.

Massachusetts: Lawrence, Sept. 1-8, 1 case.

Montana: State, July 1-31, 90 cases.

New York: New York, Aug. 25-Sept. 15, 7 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, July 28-Aug. 4, 24 cases.

Brazil: Rio de Janeiro, July 29-Aug. 12, 4 cases.

Chile: Antofagasta, Aug. 12-19, 47 cases, 9 deaths; Coquimbo, July 14-27, 12 cases, 3 deaths.

India: Bombay, Aug. 7-14, 2 deaths; Calcutta, July 28-Aug. 4, 3 deaths; Karachi, Aug. 5-12, 2 cases, 1 death; Madras, Aug. 4-10, 2 cases, 2 deaths; Rangoon, July 28-Aug. 4, 1 case, 1 death.

Italy, General: Aug. 17-23, 6 cases.

Russia: Odessa, Aug. 19-25, 5 cases, 1 death.

Siberia: Vladivostok, July 21-28, 3 cases, 1 death.

Spain: Barcelona, Aug. 21-31, 8 deaths.

Turkey: Constantinople, Aug. 20-27, 1 death.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, July 29-Aug. 5, 1 case, 1 death.

Cuba: Habana, Sept. 5-18, 2 cases.

Honduras: Ceiba, Aug. 5-Sept. 1, present.

Mexico: Merida, Aug. 25-Sept. 8, 4 cases, 3 deaths; Tuxtepec, Aug. 26-Sept. 10, 10 cases, 6 deaths; Vera Cruz, Sept. 3, 1 case, imported.

CHOLERA—FOREIGN.

India: Bombay, Aug. 7-14, 77 deaths; Calcutta, July 28-Aug. 4, 6 deaths; Madras, Aug. 4-10, 5 deaths.

PLAGUE.

Brazil: Rio de Janeiro, July 29-Aug. 12, 5 cases, 2 deaths.

Egypt: Alexandria, Aug. 17-23, 10 cases, 3 deaths; Suez, Aug. 18-23, 3 cases, 2 deaths.

India: Bombay, Aug. 7-14, 33 deaths; Calcutta, July 28-Aug. 4, 17 deaths; Karachi, Aug. 5-12, 6 cases, 6 deaths; Rangoon, July 28-Aug. 4, 136 deaths.

Mauritius: July 6-13, 1 case, 1 death.

Turkey: Trebizond, Aug. 8-13, 8 cases, 3 deaths.

Medical Organization

CONCLUSIONS FROM A COMPARATIVE STUDY OF THE STATUS OF THE MEDICAL PROFESSION IN GREAT BRITAIN AND THE UNITED STATES.

J. N. McCormack, M.D.

Chairman of the Committee on Organization of the American Medical Association.

BOWLING GREEN, KY.

A good part of my vacation has been spent in the small towns and country districts of England, Ireland and Scotland, and I have been interested in such a study of professional conditions there as would enable me to institute practical comparisons between them and those existing in our own country. I made few inquiries into these matters in the large centers of population in Great Britain, because they are already so well understood, and on the Continent, both because my time was mainly spent in the large cities or resorts and because of a lack of familiarity with the language of the respective countries.

To begin with, my former impressions were confirmed that our physicians and surgeons of the first rank will bear more than favorable comparison with those of any other land. Especially in everyday practical work, as distinguished from the research work of the laboratory, our men have a power of individual initiative, of resource, dash—to use that term in its best sense—both in medicine and surgery, not excelled in any other part of the world.

On the other hand, I got the impression, even more distinctly, that, as the result of high standards of requirements, so long established as to be fixed policies of both the profession and of government, the rank and file of medical men in Europe have had such advantages in both preliminary and professional education that there is an entire absence of the illiterate, hopeless element which forms such a large substratum in almost every community with us, and which, in spite of the rapid advance in requirements in the last few years, must continue as a perplexity and reproach to the organized profession, and a danger to the people dependent on them, until removed by time and the hand of a kind providence. Here, probably about in equal proportion as among the highly educated classes with us, a physician may be a failure for lack of practical knowledge, of the common sense essential to real success in any vocation, but, at least, he is not an ignorant loon, who does violence to his mother tongue every time he opens his mouth or writes a prescription. His preliminary and technical education have not only been such as to develop all that was possible in him, but to give him a respect for his profession, and to command a respect for it in his community, in striking contrast with what is common with a varying but considerable percentage of the profession in many sections of our own country who never should have been considered for admission to its ranks.

Because it deserves it, for the reasons stated, the profession as a whole occupies a very much higher place in the public estimation than with us. The evidence of this is seen on every hand. Health and medical legislation are far more advanced than with us, and the laws are more easily enforced, because of the solid and intelligent support of the courts and other official classes, as well as the habit of respect and obedience which these conditions naturally have engendered. Contrary to a general impression, quackery, in the forms so flagrant and offensive with us, is practically unknown here. There is some quackery, it is true, some "patent-medicine" advertising, but, as compared with what we have in most states, it is so quiet and subdued as to be almost respectable. It has no hold on their highly educated clergy, little influence with the press, and none, so far as I was able to gather, over the officials corresponding to our governors, congressmen and senators. In the same way, and for the same reasons, Christian science and other similar fads and fancies, which have taken such a hold on the educated and wealthy classes in many sections of our country as to cripple the profession greatly in its efforts to secure and enforce legislation necessary for the protection of the most vital interests of the people, and to rob it of the cream of the support to which it is so justly entitled, are subjected to authoritative scientific tests, if considered worthy of notice at all, in which the profession has a trusted voice and influence. This is illustrated in the case of Keeley, who has found it impossible to secure the support of the educated classes, which here, in contrast with our side again, always includes the official classes. I have verified this information by constant examinations of the advertising columns of the newspapers and magazines. No form of quackery can for long rob any people without the aid of its press and clergy, and our profession can not too soon be awakened to the importance of bending every energy in enlisting these agencies in the support of honest scientific medicine.

Although the cost of living is much less here, the profession is better supported than with us. In my judgment, this is because the profession deserves it. The fees are certainly better on an average, than in the older sections of our country, and the collections, in which most of our physicians are especially weak and unsystematic, are far better. This is partly because the profession has been longer and better organized, and both it and the people better trained in such matters, and probably still more because the line is sharply defined as to charity practice. The employment of medical men on fairly remunerative salaries to attend the poor is an established system, and those unable to pay for services go to the hospitals or on the rates, except of course, the worthy classes, God's poor, who find the doctor their best friend in every land. Special training is required of health officials, in addition to the ordinary medical course, but once a competent man has passed the examination and been appointed to public position, the tenure is more certain and is free from political control.

It is almost a universal custom here for physicians to dispense their own drugs, especially in the towns and country districts. Nearly all offices are in the residences and usually there is an assistant to aid in dispensing and in dressings, often some member of the family who has been given special training for such duties. This, and the usual limitation of his practice to a small area, make the life of a medical man far easier than with us, and, being near his family and library, his opportunities for social and literary enjoyment are far greater. As a result of these advantages and of his high preliminary training, nearly every one of them was found more or less enthusastic in some special scientific or literary study outside of his profession. One was a botanist, another an ethnologist or archaeologist or linguist, and the effect on the individual, on the profession as a whole, and on the community could not but be for the best.

The pleasant thought in connection with this whole matter was that it has required the continuous efforts of generations of devoted medical men, often under difficulties as great as any which can ever confront us, to bring about the present comparatively favorable, but far from ideal, conditions. They have never had any advancement in the same length of time to compare with what ours has been within the last quarter of a century. In the light of their experience and our own, we only need to maintain and to foster such wise and conservative policies for another generation as will constantly command the confidence and coördinate the efforts of every honest and worthy interest of the profession to enable us to contend generously for supremacy and to take the lead in scientific medicine, as our people hope to do in all our other relations.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Nineteenth Annual Meeting, held at Cincinnati, Sept. 20-22, 1906.

Under the presidency of Dr. John Young Brown, St. Louis.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Robert T. Morris, New York City; vice-presidents, Drs. George W. Crile, Cleveland, Ohio, and Charles L. Bonifield, Cincinnati; secretary, Dr. William Warren Potter, Buffalo, N. Y. (re-elected); treasurer, Dr. X. O. Werder, Pittsburg, Pa. (re-elected).

The time and place of next meeting were left to the executive council.

After the transaction of routine business the reading of papers was begun.

Kidney and Colon Suspension by the Use of the Nephrocolic Ligament and Gerota's Capsule.

Dr. Howard W. Longyear, Detroit, said the ligament is described as formed by an aggregation of fine fasciculi originating in and being identical with the fibrous tissue forming the framework of the fatty capsule of the kidney, which, after enveloping the kidney in a fine network, passes downward and are inserted into the posterior wall of the ascending colon on the right side, and the descending colon on the left side. Its structure, as well as its action, may be compared to that of the network covering a balloon, the cords of which descend downward and support the car. The kidney is the balloon and the cecum the car; the kidney descends or not, according to the laxity of its supports and the degree of traction exerted on it by the cecum. Dr. Longyear claimed that the traction thus exerted on the kidney by the bowel is the prime factor in the causation of nephroptosis, and as the duodenum is also displaced by reason of its adherence to the fatty capsule, the first object of attainment in any operative procedure should be the suspension of the bowel. To do this he isloates the nephrocolic ligament through the usual incision (though shorter) in the loin and suspends the bowel by overlapping and sewing flaps made from Gerota's capsule through the loop of the ligament. This also holds the kidney in suspension, but this object he considered second in importance to the suspension of the bowel.

Fixation of the Kidney by Shortening of the Nephrocolic Ligament.

Dr. Charles A. L. Reed, Cincinnati, presented a brief clinical report of cases operated on by the application of the principle, but a modification of the technic, as presented by Dr. Longyear at the meeting last year. The essential modification of the technic consists of the control of the nephrocolic ligament through an oblique incision in the intercostal interval.

The Technic of Kidney Fixation.

Dr. J. Henry Carstens, Detroit, pointed out that to fix a kidney permanently it is necessary to resect the fibrous capsule and to fix this firmly to the muscle as near to the normal position as possible. Only in this way can a kidney be firmly and permanently fixed. He described a simple operation which he said could be done in 10 minutes through a very small opening, and that it would give permanent results, and it seemed to him an ideal method of permanently fixing a kidney.

DISCUSSION ON THE KIDNEY SYMPOSIUM.

Dr. Herman E. Hayd, Buffalo, described various methods he had resorted to for fixing a kidney. He said it is not possible to fix a kidney unless one delivers it so as to produce a certain amount of adhesive union between the kidney and the loose structures which it has occupied so long.

Dr. Earl Harlan, Cincinnati, said that to understand the subject of dislocated kidney thoroughly one should be familiar with the normal anatomic relations of the surrounding organs, the nerve supply and circulation of the parts, and have a correct knowledge of the attachments and relations of the peritoneum. He called attention to the very wide range of pathologic anatomy attendant on kidney dislocations, and showed that any operative procedures, which have for their intention the correction of the numerous symptoms connected with this trouble, must be based on a correct rearrangement of the normal anatomy of the parts in the right upper quadrant. He described at length an operative technic which he had found satisfactory, inasmuch as it was based on the normal anatomy of this region.

These papers were further discussed by Drs. James F. Baldwin, Columbus, Ohio; John B. Murphy, Chicago, and Joseph Price, Philadelphia, all of whom described methods of anchoring loose kidneys.

(*To be continued.*)

WASHINGTON STATE MEDICAL ASSOCIATION.

Seventeenth Annual Meeting, held in Spokane, Sept. 11-13, 1906.

Under the presidency of Dr. George W. Libby, Spokane.

Better Care of the Insane Needed.

In the address of welcome Governor Mead stated that the insane hospitals of the state have been carried on on a purely utilitarian basis, and that he believes that no expense should be spared for suitable salaries for those who take care of the insane, as the state should have the benefit of the best medical service that can be furnished. He also said that the state can do a great deal more good than has been done in the prevention of tuberculosis.

In his annual address the president, Dr. George W. Libby, characterized the system of caring for the insane as inadequate, crude and even suggesting barbarism, and said that the laws by which the unfortunates are committed to the care of the state are not characteristic of the twentieth century civilization, but are relics of the dark ages. In his opinion, to determine whether an individual should be committed to an insane asylum, the investigation should be conducted by a commission composed of at least three physicians, one of whom should be an alienist and should visit the patient in his home. He also favored the establishment of a separate institution for the criminal insane.

To Prevent Blindness of Infants.

The association adopted resolutions favoring the passing of a law providing that any nurse who shall notice any inflammation of the eyes of an infant up to the time the child is two weeks old shall report the case to a competent physician, the penalty for failure to make such report being a fine of not more than $100 or imprisonment for six months, or both.

Supervision of Sanitary Works and Water Supplies.

The sanitary engineer of the State Board of Health also proposed a law, making it prohibitory for any municipalities, corporations or public institutions or persons to introduce a new system of water supply or sewerage in the state of Washington unless the plan for such proposed water supply or outlet for such proposed sewerage system shall have been examined and approved by the Washington State Board of Health.

The association favored the adoption of a uniform standard of medical examinations.

A resolution was passed asking that the state legislature fix the fee of physicians for examining persons charged with insanity at $10.

Election of Officers.

The following officers were elected: Dr. James H. Lyons, Seattle, president; Drs. Edwin L. Kimball, Spokane, and Ellsworth E. Shaw, Walla Walla, vice-presidents; Dr. Curtis H. Thomson, Seattle, secretary; Dr. George H. McGreer, Tacoma, treasurer, and Drs. Frank A. Scott of Pierce County, Hiram M. Read, King County, F. H. Luce, Lincoln County, James R. Yocom, Tacoma County, Robert L. Thompson, Spokane County, Henry W. Dewey, Pierce County, George W. Overmeyer, Pacific County, Lemon R. Markley, Whatcom County, Wilson Johnston, Whitman County, and C. N. Suttner, Walla Walla County, members of judicial council. The 1907 meeting of the association will be held in Seattle.

ST. LOUIS MEDICAL SOCIETY.

Meeting held Sept. 15, 1906.

The President, Dr. George Homan, in the Chair.

DEDICATION OF NEW MEDICAL AUDITORIUM.

The auditorium is located on a piece of ground adjoining the St. Louis Medical Library Building, Thirty-fifth and Pine streets. It is built in amphitheater form, with about 400 opera chairs and room for many more seats for special occasions. It has a handsome beamed ceiling and dependent chain chandeliers. The walls are polished brick.

Introductory Address by President.

Dr. Homan said in part: "Three score and ten years ago, lacking a few months, this society was ordained by an act of the General Assembly of Missouri, the expressed purpose of such legislation being the improvement of medical literature and science, and to give dignity, permanency and usefulness to this body. This body has never had a roof above it that could be called its own. The exercises arranged for this evening are in celebration of the fact that finally this reproach has been put away.

"That the present happy achievement was made possible may, it is believed, without invidious reflection, be traced to the wisdom of the society in 1895 in the selection of its treasurer who, on his induction into office, found claims amounting to several hundred dollars, and almost nothing in the treasury with which to meet this indebtedness. But gradually, by prudence, thrift and good management, better business methods were introduced; and, after eight years of such faithful service, when he was called to the presidency, a very comfortable bank account had been accumulated to the credit of the society, and from this nest egg has sprung the edifice in which we are now assembled. The funds thus made available for investment in this property have been supplemented by contributions secured chiefly from the membership, and while the individual response to this appeal has been liberal as a rule, all things considered, still the names of very many of our members have not as yet appeared in the list of givers to this cause, but the hope is confidently indulged that such oversights and omissions will promptly be repaired when the situation is better understood.

"There are present here to-night some who have come down from a former professional generation, and who have personal knowledge of the vicissitudes and embarrassments that beset and confronted the organized profession here in earlier years, progress being hindered perhaps by bickering or belligerency, often due to mere misunderstanding or imperfect acquaintance, and leading to occurrences that were regrettable and sometimes even injurious to the advancement of scientific work and the promotion of lasting harmony among brethren.

"Happily for us of to-day, a more pacific spirit seems now to be in the air, a disposition to cultivate peace that extends even to nations which are rivals and competitors in many fields, and if this spirit can be brought sensibly to bear in the sharp contentions of races and governments, there is small excuse for a different manifestation among those so advanced in humane civilization as the medical profession is universally conceded to be.

"As the climate of feeling and opinion generally appears to have become more moderate, this occasion presents a most fitting opportunity to express the sincere hope that no wrongful or unkind contention between members may ever be brought across the threshold of this building; that the supreme, the controlling obligation of thorough, honest, unflagging scientific work shall never be lost sight of within these walls; that the doors shall never be closed to the truth, howsoever unwelcome it may appear at the time or by whom presented; that this roof-tree shall be broad enough to afford hospitality and welcome to every honest thinker who believes that he has a new message to deliver for the betterment of his fellow-men—in short, that here is a temple dedicated to truth, science, progress; consecrated to peace, concord, unity, good will, so that the generations yet to come may be the better for our lives and labors, and gratefully say: 'They are justified in their works; they builded even better than they knew!'"

Early History of Society.

Dr. LeGrand Atwood, one of the oldest living members of the society, said, among other things, that his acquaintance with the society dates back to 1846, when he first attended its meetings. The first discussion he had heard on the floor of the society was one between Drs. Johnston, Hammond and McPheeters. These men were faithful to the requirements of the profession. He said that the first attempt at organization of this society occurred on Dec. 25, 1835, when a meeting was held in the old Masonic Hall in this city. Dr. William Carr Lane was once president of the society. Dr. Lane was elected eight times mayor of the city of St. Louis, only refusing the office again because of stress of professional labor. The speaker called attention to the greatness of Dr. Lane from a medical as well as from a civic standpoint, and said that he hoped that at some future time the physicians would succeed in having a monument erected to him in City Hall Square. At the meeting above alluded to the society was formed and organized. At a meeting on Jan. 2, 1836, the constitution was adopted. The officers for 1836 were: Dr. J. G. Farrar, president; Dr. Lane, vice-president; Dr. B. B. Brown, recording secretary, and Dr. Y. B. Bouting, treasurer. On Jan. 15, 1836, the by-laws were drafted and adopted. The first paper read before the society in regular session assembled was entitled "Does Epidemic Contagious Puerperal Fever Exist in St. Louis?"

Dr. Farrar was the first American physician in St. Louis. The other physicians were French. On Sept. 24, 1836, the St. Louis Medical Society appointed a committee to confer with the faculty of the St. Louis University, relative to the establishment of a medical school in this city. Later in the same year the society took up the matter of disciplining some members who were advertising in the daily papers. The society also took up the matter of keeping a record of births and deaths, which forms the basis of the present-day mortality records of the health department. Dr. Barnett at this time offered a resolution governing the sale of milk, which is the first attempt at pure-food legislation here. A committee took up the matter of preventing the spread of contagious diseases.

In 1850 the society adopted the Code of Ethics of the American Medical Association. In 1877 the society adopted a resolution that only medical men be appointed health commissioners of the city. In 1887 Dr. McPheeters introduced a resolution calling for the creation of a real estate and building committee, for the purpose of securing a permanent home for the society. The project was dropped on account of inability to secure money enough to buy the property.

Reports of Committees.

Dr. R. M. Funkhouser, chairman of the finance committee, reported briefly that there was a small balance of the money subscribed by the members remaining, but that several thousand dollars had been borrowed from the bank to complete the building of the auditorium. He stated that he was ready to receive new subscriptions to cover this loan.

Dr. Pinckney French, chairman of the committee on business affairs, received the keys of the building from the president and addressed the members on the need of paying off the loan spoken of by Dr. Funkhouser. Dr. French proved that his reputation as a financier was well grounded by obtaining practically all the needed money, he leading off with a generous subscription, followed by Drs. Outten and Homan and others.

Dr. A. R. Kiefer, chairman of the building committee, and Dr. John C. Morfit, chairman of the committee of arrangements, also reported.

Medical Profession of St. Louis of To-day.

Dr. W. B. Outten ascribed the difficulties in the past in the way of unification of the city's profession to the Civil War and its political effect thereafter. He said that up to 1864 the profession was powerful, influential and united in its work in St. Louis, that St. Louis was a great medical center, but that from 1864 to 1895 elements adverse to the St. Louis medical profession took deep root and hampered the work. He said that in spite of the great adversity and strife in the ranks of the profession, the St. Louis Medical College lived on. He rendered a tribute to this college for its unflinching spirit in times of adversity. For the future he predicted great things of the St. Louis Medical Society and the profession of that city.

Future of the Medical Profession of St. Louis.

Dr. W. G. Moore called attention to the altruistic work of the men who have attended regularly the meetings of the city and state societies, men who have gone by circuitous roads of travel to state meetings, neglecting their business purely for the purpose of maintaining an organization. He spoke of the great work of organization of local and county societies, which has been so well stimulated by the American Medical Association. He said that this society will become the society of the young men before him. The young men must perpetuate it.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fifteenth Annual Meeting, held in Buffalo, N. Y., Sept. 11-14, 1906.

(*Continued from page 956.*)

The Russian Red Cross.

Col. Valery Havard, assistant surgeon-general U.S.A., described the origin, development and history of the Russian Red Cross Society, which was founded during the Crimean War as the "Committee of the Exaltation of the Cross." In 1867 the name was changed to "Russian Society for the Assistance of Sick and Wounded Soldiers," and in 1876 the society assumed its present name. The society was organized under the laws of the empire and has active and honorary members, contributors and benefactors. The executive power is vested in a central committee, to which state and local committees report. For the work of the society during the Russo-Japanese War, Manchuria and eastern Siberia were divided into five zones, and the work undertaken included the establishment of supply depots, transportation of the sick and wounded, assistance to the medical military service, direction of the relief of the sick and wounded, and the organization of feeding stations. The author believes that such societies are invaluable and indispensable in war, and that a Red Cross society to be efficient must be not only well organized, but every member should acquire a practical knowledge of first-aid and should have had experience in the handling of patients.

Tendon Tissue versus Catgut.

Col. Nicholas Senn, surgeon-general, Ill.N.G., gave a history of ligatures and suture material. The first animal ligatures were introduced by Dr. Paul Eve, Nashville, Tenn., and Dr. Christian Linde, Oshkosh, Wis., who used for this purpose split deer tendon. Lord Lister was the first to show the way to the successful employment of antisepsis in suture and ligature material, and the principles which he taught still remain. Silk, silver wire, horsehair and silkworm gut will continue as substances for removable sutures, but can not hold their present position as material for buried sutures. The material known as catgut is not the intestine of the cat, but is made from the small intestine of the sheep, and is open to the objection that it is exceedingly difficult to sterilize and render aseptic. Tendon tissue, in the author's opinion, is preferable to catgut, because it is made of straight fibers running parallel with each other; and because it is obtained from the cleanest part of the animal. It is stronger than catgut, which is made up largely of muscular tissue. It does not loosen as does catgut under the influence of moisture, and tendon material can be made aseptic by the same methods as catgut. In 1878 Ischiguro, surgeon general of Japan, made a report on whale tendon, which he advocated for suture material. The so-called kangaroo tendon, which had a great vogue, is not made from the tendon of the kangaroo, but from a smaller animal of the same family, the wallaby. The author advocated the use of the tendons of the arctic sea animals, the narwhal, walrus, whale, etc. The tendons on either side of the spine are used for this purpose, and in the case of the narwhal they can be split into fine threads, four feet or more in length. The walrus tendon is coarser, but possesses similar advantages, and the same applies to the tendon from the back of the whale. Dr. Senn has used this coarser tendon with success in operations for the radical cure of hernia and recommends its use for suture and ligature material on account of the abundance of the supply and the inexpensiveness when once on the market. He stated that he obtained in the arctic region last summer a supply of tendon material sufficient for the use of a large hospital for an entire year, in exchange for a pound or two of powder.

Identification by Finger Prints.

Surgeon Charles P. Wertenbaker, U.S.P.H.&M.-H.S., called attention to the fact that no two persons have identical finger prints, and spoke of the interest in the development of the identification of individuals by this means. The method consists in taking an impression of the lines or markings on the thumb or one or more of the fingers. The thumb is pressed lightly on an ordinary rubber stamp pad and then pressed firmly on the surface which is intended to receive the impression. The value of the system results in the fact that the lines of the fingers of no two persons are alike and that the lines of the fingers of an individual are unchanged from the date of his birth until the time of his death. The markings of the right and left hands are practically the same, except that the lines run in opposite directions. The marks of all fingers also are practically the same. Identification by the use of finger prints has been in use in China for several centuries. In India the British government adopted identification by finger prints in lieu of signatures in legal documents, receipts, etc., many years ago, because of the difficulty in securing the names of individuals which, under the peculiar conditions existing there, frequently changed. Last summer while on duty during the yellow-fever epidemic in the South Dr. Wertenbaker employed this method to prevent the transferring of certificates of persons traveling in certain portions of the South, to show that they had not been exposed to the infection of yellow fever. This practice, which was general, he completely stopped by adopting the following method of identification: A description of the individual, giving his nationality, age, height, color of hair and eyes and special marks; the signature and the impression of the ball of the right thumb. Finger marks may be classified as open loops, closed loops, "S" loops, whorls, and varieties combining the previously named classes. The United States Army has recently ordered that the thumb and finger-print system of identification be introduced in the recruitments for the Army, supplanting the outline figure card, and the finger prints, together with the photograph, now form a part of the descriptive card of each recruit. Dr. Wertenbaker considers this method less complicated and more sure than the Bertillon method of examination.

Splenic Abscess Following Malaria.

Surgeon William H. Bell, U.S.N., read a paper based on three cases of splenic abscess, following as a complication to grave malarial infection. He discussed the pathogenesis of the condition and emphasized malaria as a disease important in the etiology of splenic abscess, demonstrating theoretically why the conditions should be of frequent occurrence. He suggested a procedure for direct experiment to determine the tenability of the theoretical premises, and concluded with a review of the symptoms and signs of the disease, and remarks on prognosis and treatment.

BRITISH MEDICAL ASSOCIATION.

Seventy-fourth Annual Meeting, held in Toronto, Ontario, Aug. 21-25 1906.

(Continued from page 959.)

SECTION OF ANATOMY.

Arthur Robinson, M.D., Birmingham, the president, in his introductory remarks on "The Teaching of Anatomy in Universities and Public Schools," gave a sketch of the history of the teaching of anatomy. Men of an inquisitive turn of mind first studied it, so that they might know as much as possible about themselves and their fellows. They probably hoped that a knowledge of the structure and arrangements of the various parts of the body would be of service in the attempt to meet and avoid those infirmities and diseases which they knew to be the precursors and the possible causes of death. The knowledge thus acquired was utilized by those who undertook the treatment of injuries and diseases of the human body, and gradually the study of the details of human anatomy passed into the hands of priests, who provided for the bodies as well as for the souls of their flocks, and later into the hands of the members of the medical profession.

There is still a tendency in some quarters to decry the wider knowledge of anatomy as a science and to insist that the medical student shall be taught only the technical details of the human anatomy, that is, the position of organs and parts and their relationships to each other. Nothing could be more harmful to the best interests of the medical profession and the public than the adoption of such a view. It would result in the medical man becoming a mere mechanic, who can do well what he has been taught to do or has seen done, but who is absolutely useless when he desires to do something that requires general as well as special knowledge. Fortunately there are many broad-minded men in the profession who have recognized that the man who has a wide knowledge of general principles is better adapted to meet unexpected circumstances than the one who is provided merely with a memory of certain observed facts. Consequently, the teaching of anatomy in a large number of institutions has passed into the hands of men who are enthusiasts in its teaching and study, and have spent the greater portion of their lives in the study of the subject. This should be still more the case in the future. This forward movement is attended by the danger that specialists occasionally lose sight of the practical application of their work and teach only its more interesting features from a scientific viewpoint. This danger will be avoided if the electing bodies of teaching institutions employ as teachers only men who have been through the medical curriculum and understand the needs of the profession.

Teachers of anatomy should also habitually take part in the meetings of medical associations, and thus keep in touch with the general knowledge of the profession and its relationship to their special branch. The object of the nts that beset riculum is to give the student a wide knowledge earlier years, ciples on which he must rely in the practice of his belligerency, a sufficient knowledge of the details to prevent the acquaintance, any serious mistake, and a sufficiency of general knownd some- enable him to take his place as an accepted membefic work medical community. It should, therefore, be the object anatomist to avoid engaging the student in a superfluity now details. He should insist on a sound knowledge of the generends relationship of the most important parts of the body, and a good knowledge of the general principles which underly these relationships and the advantages derived from them. He should make his students acquainted with the general laws of growth and development and abnormal conditions produced by deviations from these laws. He should draw attention to the relation of man to other animals in all cases where such relations are evident. In addition, he should see that his students acquire a sufficient knowledge of the details of the various parts of the body and their relationship to enable them to cope successfully with any emergency of daily life, but he should impress on his students that it is more important that they know the various principles on which the various systems or organs are constructed and those on which they are modified, than that they should memorize the details, which may be found at any time in the numerous text-books.

SECTION OF PHYSIOLOGY.

Proteid Nomenclature.

Prof. W. D. Halliburton, M.D., F.R.C.S., the president, in his introductory remarks considered the question of proteid nomenclature. The recommendations of the Chemical Society of London, several years ago, have never been universally adopted by those who write or speak English. This committee suggested the termination of *ol* for alcohols, *ine* for basic substances, and *in* for materials of more indefinite structure. In America, where some support should have been anticipated, the non-conforming conscience has asserted itself with the resultant tendency toward Germanizing rather than Anglicizing chemical names. Thus creatine is spelled kreatin; sulphur, sulfur, and the final e in chlorides, sulphates and other salts is usually absent. He then took up the change in the chemical conception of the proteids and the selection of a general name for the entire group of albuminous compounds. The term "proteid," used in England, is restricted to a sub-group (the conjugated proteids) by the Germans; the word "albuminoid," employed by analytical chemists in England and by French physiologists in the same sense, is restricted to the heterogeneous group of which gelatin and keratin are instances, by German and English physiologists. The word "albumin" is very generally bestowed on a sub-group, and its adoption as a family name would make worse the present confusion. After much deliberation "protein" was recommended as a general name, and the following sub-classes were suggested:

1. Protamines.
2. Histones.
3. Albumins.
4. Globulins.
5. Sclero-proteins.
6. Phospho-proteins.
7. Conjugated Proteins.
    (a) Gluco-proteins (for example, mucin.)
    (b) Nucleo-proteins.
    (c) Chromo-proteins (for example, hemoglobin.)

For classes 3 and 4 no general term has been found which will prove acceptable, "heat-coagulable proteins" and "albugin" were suggested, but universally disapproved. The committee also recommended that the products of protein hydrolysis be classified as follows:

1. Infra-proteins, to replace albuminates, the termination of which implies a salt and so is objectionable.
2. Proteoses, which include albumose, globulose, gelatose, etc.
3. Peptones. It was proposed that this should be restricted to those further products of hydrolysis, which cannot be salted out from solution, but which nevertheless, still give the biuret reaction.
4. Polypeptides. These substances are still lower down, not as a rule, giving the biuret reaction, but their exact relations to peptones is still undetermined.

Transplantation of Blood Vessels and Organs.

uis of To-day.

Address of President.

in the past

Dr. William H. Hartzell, Allentown, stated that when the society last met at Bedford Springs, 19 years ago, the membership was 800, whereas now it is over 4,500, which increase he attributed to the increased feeling of unity among the profession. He urged the necessity for further enlightenment of the public in hygiene and sanitation, because thereby the mortality from many diseases, such as typhoid and tuberculosis, will be decreased. He pointed out the necessity for the correction of the dispensary abuse, and condemned contract practice for lodges, etc. He also reviewed the advances made in the various domains of medicine, particularly in surgery and laboratory diagnosis.

Treatment of Inebriates and Dipsomaniacs.

Dr. Theodore Diller, Pittsburg, commented on the Act of Assembly of April 9, 1903, providing for the commitment and detention of inebriates and drug habitués, and stated that in order to make the act effective there is needed a hospital or asylum for commitment. He described in detail various state hospitals, particularly those in Iowa and Massachusetts. He believes that the lack of such a hospital is the means of causing many inebriates, etc., to become inmates of quack institutions.

DISCUSSION.

Dr. John B. Carrell, Hatboro, stated that he had communicated with various authorities on this subject, and the consensus of opinion seemed to be that a separate institution is necessary. The opinion as to permanent cures varies widely, ranging from 1 or 2 to 75 or 80 per cent., and that the most common etiologic factor is an unstable nervous system produced through heredity and wrong notions of sociability.

Dr. Lowell M. Gates, Scranton, believed that a comparatively short time, a few weeks or months, is necessary to cure these cases, provided they would not afterward be subjected to temptation. The best results would be obtained by the enactment of prohibitory laws in this direction.

Dr. Charles K. Mills, Philadelphia, stated that a separate institution should be established, and that the predisposing cause to inebriety is the hereditary condition of the inebriate and his family.

Dr. Charles W. Burr, Philadelphia, recited the provisions and practice under the Pennsylvania law for the commitment of the inebriate, referring particularly to the fact that no provision is made for those who can not afford to pay. He does not feel, however, that separate institutions are absolutely necessary, but that the inebriate can be treated successfully in the insane hospitals under proper regulations. Only a few of the cases can be cured, some being of such a character that a radical cure is not possible.

every member should acquire a practical knowledge of first-aid and should have had experience in the handling of patients.

Tendon Tissue versus Catgut.

Col. Nicholas Senn, surgeon-general, Ill.N.G., gave a history of ligatures and suture material. The first animal ligatures were introduced by Dr. Paul Eve, Nashville, Tenn., and Dr. Christian Linde, Oshkosh, Wis., who used for this purpose split deer tendon. Lord Lister was the first to show the way to the successful employment of antisepsis in suture and ligature material, and the principles which he taught still remain. Silk, silver wire, horsehair and silkworm gut will continue as substances for removable sutures, but can not hold their present position as material for buried sutures. The material known as catgut is not the intestine of the cat, but is made from the small intestine of the sheep, and is open to the ob-
jection that it is exceedingly difficult to sterilize and rer .es in
aseptic. Tendon tissue, in the author's opinion, is pre higher
to catgut, because it is made of straight fibers runnir .ent of asep-
with each other; and because it is obtained fr ..ne places; the lat-
part of the animal. It is stronger than ca .n to the necessity of
up largely of muscular tissue. It removal.
does catgut under the influence of
terial can be made aseptic .y of the Nervous System.
In 1878 Ischiguro, surge EISENBURG, Philadelphia, urged the ne-
whale tendon. .y surgeon knowing more of the anatomy of the
so-rvous system, and stated that exploratory operation for the relief of intracranial pressure, headache, etc., is justified as a palliative measure, even if radical removal of the causative factor is not possible.

SYMPOSIUM: SURGERY OF THE HEAD AND SPINE.

Cranial Injuries.

Dr. Daniel A. Webb, Scranton, considered late cerebellar abscesses of traumatic origin, and after referring to the literature of the subject, particularly the diagnosis and the relation of trauma to the abscess, stated that the only treatment for the condition is operative. He reported the case of a miner, 29 years of age, who six years previously had suffered a cranial injury by a fall of coal. When admitted to the hospital he was suffering from headache and difficulty in articulation. The case was diagnosed as one of cerebellar tumor, but after death it was discovered to be a deep-seated abscess of the middle lobe.

Fracture of Base of Skull Resulting from Direct Violence Through Inferior Maxilla.

Dr. Alexander G. Fell, Wilkes-Barre, cited the case of a man, aged 25, who during a fire fell from a porch, a distance of 20 feet, striking on the point of the inferior maxilla, causing a complete, compound, comminuted fracture between the median line and the left mental foramen.

Present Status of Cranial Surgery.

Dr. Charles H. Frazier, Philadelphia, reviewed the general progress made during the past decade, and considered particularly the surgery of epilepsy; of hemorrhage of the newborn and in childhood; of the cranial nerves; of tumors, and urged that if operation was to be done at all, it should be performed early.

Unusual Case of Trauma of Head, Exhibiting Symptoms of Astereognosis.

Drs. John H. W. Rhein and Edward Martin, Philadelphia, reported this case, which followed an attack of acute otitis media. After cleaning out the cavity and washing it with pure carbolic acid (which was afterward neutralized with alcohol), the man made a good recovery.

Impaired Cerebral Development Due to Other Than Cranial Causes.

Dr. Ernest Laplace, Philadelphia, mentioned adenoids, tongue-tie and phimosis, which conditions, he said, should be corrected as promptly as possible where no brain lesion is found. Eighty-two cases which have come under his care resulted very satisfactorily.

DISCUSSION.

Dr. Charles K. Mills, Philadelphia, stated that headache is a more valuable diagnostic symptom in brain abscess than in
closed loops.ation for brain tumor should be performed so
previously e are sufficient symptoms to diagnose the case.
cently orde .les W. Burr, Philadelphia, urged the importance of
tification. iagnosis and more prompt surgical interference in
planting brain tumor.
gether William G. Spiller, Philadelphia, urged the importance
tive .fferentiation as to location of the lesion, whether cortical
met subcortical. He also recommended the removal of a portion
m the bone in cases of enlargement of the bones of the skull, and reported two cases, one a syphilitic tumor and the other a tumor following an injury in which each patient made a good recovery.

Dr. Levi J. Hammond, Philadelphia, felt that those cases with a history of suppurating middle ear, loss of flesh, lowering of pulse and disturbance between relation of pulse and temperature strongly suggest cerebellar tumors.

Dr. William L. Rodman, Philadelphia, reported the case of a man suffering from constant vomiting, which had been diagnosed by the local physicians as a diseased condition of the stomach, but which after death proved to be an extensive tumor of the right half of the cerebellum. He believes that in most cases the peripheral operation is to be preferred to the more general one.

Dr. George W. Guthrie, Wilkes-Barre, stated that he had almost invariably secured good results in the treatment of traumatic injuries of the brain, while the contrary had been almost as uniformly the case in traumatic injuries of the spinal cord.

SECTION ON EYE, EAR, NOSE AND THROAT DISEASES.

Chairman's Address.

Dr. Samuel D. Risley, Philadelphia, said that the society had taken an important step toward the fulfillment of its ideals, for the advancement of scientific medicine, by providing for the classification and division of its work by creating sections. Formerly only such subjects as are of general interest were presented. When special subjects were introduced it had the effect of driving out of the room those of the auditors not interested in the particular organ under consideration. Therefore, members working in special fields would seek other avenues than the state society for the presentation of their results. Dr. Risley advocated that a change should be made in the rule that compels the sole publication of papers in the journal of the society, as he thought that it prevents the presentation before that body of fresh or original work, the publication of which might be deferred for an entire year. He also made a plea for physicians not to become exclusively interested in their specialties, but to keep up with the advances in general medicine and surgery; and also not to be ignorant or indifferent to the specific affections of other organs than the one selected for the special field of endeavor. The general practitioner also can not afford to ignore the increase of knowledge to be gained by attendance on the work of the section on specialties.

Local Infection from the Conjunctiva and the Lachrymal Passages.

Dr. Edward A. Shumway, Philadelphia, said that infection after operation is now known to depend on the presence of micro-organisms within the conjunctival sac. The bacteria that are normally present there are greatly increased in number by inflammation of the conjunctiva and the lachrymal passages. Infections of the eyeball fall into two classes: those that involve the cornea in the form of ulcers, and those that involve the entire ball. Ulcers of the cornea are produced by a great variety of organisms. Infection, in the majority of cases, presupposes an injury to the corneal epithelium. Infection of the globe may result from the perforation of ulcers, or may follow penetrating injuries or operation during which the eyeball is opened. It is probably not possible for bacteria to pass upward from the nasal chambers through the lachrymal passages to the eye; but, in the presence of a stricture of the duct, the sac forms an excellent breeding ground for the organisms, and these readily overflow on the conjunctiva. The treatment of even minor injuries is, therefore, of considerable importance. Dr. Shumway described the treatment fully.

(To be continued.)

Travel Notes

DISEASE AND HOSPITALS OF THE INTERIOR OF SOUTH AFRICA.

NICHOLAS SENN, M.D.
Professor of Surgery in the University of Chicago and Professor and Head of the Surgical Department of Rush Medical College.
CHICAGO.

(*Continued from page 962.*)

SANITATION IN JOHANNESBURG—DISEASES OF CENTRAL SOUTH AFRICA.

The great diamond mines of Kimberley and the richest gold mines in the world at Johannesburg are only fifteen hours apart by rail. Nature has deposited here within this limited space her richest treasures in the very heart of what was but a few years ago the Dark Continent. These mining cities are situated on the highest elevation of the interior plateau of South Africa, and the diseases prevailing here are representative of the diseases of that part of Africa. Thanks to Dr. Charles Porter, the health officer of Johannesburg. I was given every facility to get a good insight into this subject, besides familiarizing myself with sanitary matters in the city of Johannesburg. The city has about 210,000 inhabitants, 80,000 whites, the same number of negroes, and 50,000 Chinese. Dr. Porter is the busiest man in the city. He has made sanitation his specialty since his graduation in medicine. For several years he was health officer of an important city in England, and came here to take the position at a salary of $10,000 per year, and with the understanding that his work should not be hampered by politics. He is the most enthusiastic and energetic health officer I have ever met. He works without a let-up from morning until night. I spent a whole forenoon with him in visiting his various establishments, destructor, sewage compound, lazaretto and isolation hospital, scattered over a considerable part of the outskirts of the city, and I became deeply impressed with his knowledge of sanitation and the efficiency of his work. A large disinfection plant with the most improved sterilizers is in operation in connection with the lazaretto. The destructor, where all garbage is cremated, was of special interest to me. Part of the ashes from the destructor entered into the composition of an artificial stone used for paving sidewalks and sewer pipes, both of which are manufactured on the premises, and are a source of considerable income to the city. The sewage is collected in carts by a small army of blacks who live in a compound adjacent to the disinfecting station. From a common point, the sewage is conveyed to a safe distance from the city and tipped into abandoned mines or other available places. Dr. Porter's next great project will be the building of a model abattoir, for which he has already selected the site and material and drawn the plans. He is paid a large salary, but it is well invested for the improvement and health of the city.

In his annual report for the year 1903, an admirable publication, he has this to say of the causes and prevalence of pneumonia: "It is, however, generally agreed that pneumonia is an infectious disease and that it is predisposed to by devitalizing influences of any kind, such as irregularities and excesses of life, insanitary environment, overcrowding and air pollution, as well as by inferior and insufficient food, and neglect of precaution against the sudden changes of temperature characteristic of the South African climate. Furthermore, there can be little doubt that the very great amount of dust with which Johannesburg is liable to be afflicted in the dry season, has had a very considerable share in the production of the disease, and this view is confirmed by the fact that dust taken in May in Market Street and Fox Street has been shown to be as sharp, angular and irritating as that taken from the mine slopes. Finally, as the 'spit' of pneumonia patients swarms with the germs of the disease, there is little doubt that the disgusting habit of spitting, especially inside dwellings, bars and public vehicles, is an appreciable factor in spreading the disease." In the mortality statistics for that year, diarrhea and dysentery are credited with 157 deaths, including 108 children under 1 year of age; pneumonia with 115, and "Rock drill pneumonia," or miner's phthisis, with 52. There can be no question as to the direct etiologic relationship of street and mine dust to bronchitis, pneumonia and tuberculosis, at least as a predisposing cause, by preparing by their mechanical irritation, a point of least resistance in which the essential microbic cause, pus microbes, pneumococci and the bacilli of tuberculosis locate, multiply and exercise their specific pathogenic effects, producing the characteristic type of inflammation. The health reports in Johannesburg, published in excellent form by Dr. Porter, are interesting in showing the kind of diseases physicians have to deal with on the high mountain plateau of South Africa.

The water supply of Johannesburg is obtained from wells 60 to 90 feet deep, drilled in the solid rock, and yielding an abundance of pure potable water. During one of the outbreaks of typhoid fever, Dr. Porter traced the infection to one of the wells, which had become contaminated through a fissure in a rock which led into the well. There are other sources of typhoid infection in the city; the removal of night soil in carts, the dust and the ignorance of the natives regarding matters of health, have contributed their share in propagating the disease, in a place supplied with water, usually free from typhoid germs. Through the energetic influence of the officer of health, a hotbed of disease was removed from the very center of the city, where a large settlement of blacks lived in filthy crowded huts. By prompt action of the city council, the recommendation of Dr. Porter to condemn the huts, remunerate the natives for their loss and colonize them outside of the city limits, was adopted and carried out, and the cleared space has now become a desirable place for private residences and business establishments, and the natives have been likewise benefited by the change.

During the year 795 cases of typhoid fever were reported to the health office, 710 whites and 85 blacks. Of the white patients, 206 were persons who either came into Johannesburg suffering from the disease, or developed it in two or three days after arrival. The total case mortality for the whites was about 13.8 per cent., while for the blacks it was 56.5 per cent., but the total number of blacks attacked (85) is hardly large enough to allow any safe conclusion to be drawn. The excessively high mortality among the blacks was, in all probability, due to the fact that only grave cases were seen by physicians, as well as improper diet and lack of nursing.

A glance at the tables giving an account of infectious diseases reported during the year, gives a good idea of the prevalence of these diseases, not only in Johannesburg, but all over the central part of South Africa and Cape Colony. The whole number of cases reported was 1,775. Among these I will give the figures of the more important diseases only; Typhoid fever, 795; gastric and typho-malarial fever, 5; malaria, 56; scarlet fever, 220; chickenpox, 155; puerperal fever and puerperal sepsis, 20; dysentery, 402; diphtheria, 66; membranous croup, 7, and erysipelas, 48. In this list two cases of leprosy are included. These figures show conclusively that the high plateau region of South Africa is almost free from tropical diseases, and that its healthfulness compares favorably with that of any other country. The climate is delightful, the air dry and bracing, the nights cool, and the day heat, even in midsummer, not distressing.

JOHANNESBURG HOSPITAL.

Johannesburg Hospital is the only general hospital in the city. A small hospital for the employés of the Rhodesia Railroad I did not visit. The Johannesburg Hospital is eighteen years old, has undergone many important changes since that time, and has been enlarged with the growing needs for accommodations for the increasing number of ill and injured. The hospital occupies a commanding position on one of the many hills of the city, and is surrounded by large grounds made attractive by paths, trees, shrubs and flowers. The hospital at present has accommodations for 380 patients. A large number of private rooms and a few small private wards are a source of material revenue with which to defray the heavy expenses of the institution. The main building and wings are two stories high and constructed of brick. The blacks are housed in two one-story cottages in the rear. In the ward for black women I counted only 13 patients. The number of black male patients in another ward was much larger.

I was much pleased to find a free bed in one of the general wards for Europeans in memory of the late President Kruger, established and to be maintained by friends of the deceased. The report of the hospital for the last year makes the following allusion to this: "As a memorial to the late President Kruger, about $1,000 was collected by several lady residents of the town and handed over to the board for the purpose of maintaining a bed in the free male wards. The board's thanks having been conveyed to the organizers, the bed was formally opened by General Beyers in the presence of the hospital board and staff, Dec. 21, 1904, and a brass plate giving the designation of the bed placed at its head."

Mr. G. E. Murray, F.R.C.S., does most of the operating and, so far as I could learn, is the most prominent surgeon in the city. We found him in the capacious operating room, which is well lighted and fairly well equipped, engaged in an operation for femoral hernia. His principal assistant was one of the sisters of the hospital, who has charge of the operating room. Mr. Murray used iodized catgut exclusively for buried sutures and ligatures, and is well pleased with the results, as since he has adopted this material, stitch abscesses in aseptic wounds are almost unknown. A few cases of cancer in the black have been observed in this hospital, but no cases of appendicitis.

It is a little strange, that in this city with more than 100 doctors, the hospital has not opened its doors so freely as it should to physicians who do not belong to the staff. A movement is now on foot to remedy this lack of hospital space by the building of another hospital for the outsiders, and this is certainly an effort in the right direction. The nursing is in care of 25 Anglican Sisters and 80 pupil nurses. A new nurses' home is on the way to completion at an expense of more than $100,000. The nurses have to undergo a course of instruction and training extending over three years before they can come up for the final examination. Graduate nurses in private practice are paid $25 a week. This liberal pay of private nurses is a great incentive for young women to enter the training school. The annual report of the hospital for 1905 shows that the whole number of indoor and outdoor patients, paying and free, was 12,398, of which 7,919 were outdoor patients. Of the 4,459 indoor patients, 3,256 were whites and 1,203 colored, and of these, 1,915 paid full hospital fees, 74 partial fees and 2,470 were treated free of charge. The average percentage of white-paying patients was 44, and of colored 44, certainly a good showing for the latter.

The government grant in aid for the year amounted to $75,000. I will omit reference to the medical statistics of the hospital, as it would be largely a repetition of what I have quoted from the report of the officer of health, Dr. Porter. A few notes from the surgical statistics will be of interest. Of 18 cases of attempted suicide, all Europeans, 7 died; of 253 cases of fractures of all kinds, the injury or its complications proved fatal in 25; out of 5 cases of intestinal obstruction, all white patients, only one died. Hernia appears with 40 cases, with 3 deaths, and strangulated hernia with 9 cases and 2 deaths. Appendicitis is credited with 52 cases, and of these patients 4 died. Pelvic surgery takes a conspicuous position in the surgical statistics and is headed by salpingitis with 26 cases in the white and only 2 in the black, with 2 deaths. Vesicovaginal fistula occurred five times. Among the rare operations, we noted one for pancreatic cyst and one for exstrophy of the bladder. Nowhere in Africa does stone in the bladder or kidney appear to be common. In this list we find only 2 cases of stone in the bladder and none of stone of the kidney. Of 25 cases of stricture of the urethra, only 2 were in colored patients. It is a very noteworthy fact that all cases of congenital and acquired deformity were white patients. These cases were 6 of harelip and cleft palate, 1 of spina bifida, 5 of clubfoot, 2 of hammertoe and 1 hypospadias. The surgical statistics cover almost the entire field of surgery, and the results certainly speak well for the operators of Johannesburg.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen in every-day practice.]

Intestinal Dyspepsia—A Correction.

In The Journal, Sept. 22, 1906, page 964, second column, near the bottom, the word *salve* appears in place of *salol.* Although the procedure would be harmless, we trust that none of our readers have made internal application of the external remedy inadvertently suggested. The prescription should read:

For putrefactive diarrhea with abdominal pain:

R.	Bismuthi subgal.	ʒii	8|
	Salol	gr. xxiv	1|65
	Ext. opii (denarcotized)	gr. iii	|20

M. Ft. capsulæ No. xii. Sig.: One capsule before meals.

Tertiary Syphilis.

In the treatment of the tertiary stage of syphilis J. C. Wilson, in *Applied Therapeutics,* states that the iodids are of more benefit than the mercurials. Unless the mercurials are administered with the iodids, however, the patient will in most cases suffer a relapse. The quickest and most positive results are, as a rule, obtained by combining the two, which produces a combined effect on the syphilitic virus that is not obtained by one of these preparations when given alone. The administration of the iodid, according to Wilson, hinders the elimination of the mercury by the kidney, so that a longer time is required for the process, as the mercury remains stored in the tissues and prevents relapses.

A course of potassium iodid should not be continued too long, and if improvement is not shown by its administration by the end of six weeks or two months, some other treatment should be instituted. Whether the iodids should be combined with the mercury or given separately, as well as the size of the dose to be given, should be governed by the character of the lesions, their extent and the part of the body involved. If the patient should be suffering from the skin eruptions of late syphilis, the mercury and iodids should be combined, and iron should be added if anemia is present. The author recommends the following combinations:

R.	Hydrarg. chloridi corros.	gr. i	|06
	Kalii iodidi	ʒii	8|
	Syr. ferri iodidi	fʒiv	15|
	Syr. sarsap. comp	f℥iii	90|
	Aquæ q. s. ad	f℥vi	180|

M. Sig.: One tablespoonful three times a day after meals, in water.

Mercuric iodid may be substituted for the corrosive sublimate as follows:

R.	Hydrarg. iodidi rubri	gr. iii	|20
	Potassii iodidi	ʒii	8|
	Syr. sarsaparillæ co	f℥iii	90|
	Aquæ q. s. ad	f℥vi	180|

M. Sig.: One tablespoonful in water three times a day.

When a tonic is indicated in conjunction with the specific treatment, Wilson recommends the following combination:

R.	Hydrarg. chloridi corros	gr. i	|06
	Tinct. ferri chloridi	fʒii	8|
	Liq. arsenii chloridi	gtt. xlviii	3|20
	Potassii iodidi	ʒii	8|
	Syr. zingiberis	f℥iii	90|
	Aquæ q. s.	f℥vi	180|

M. Sig.: One tablespoonful three times a day, in water.

Patients who suffer from pain in the bones, constant headache or syphilitic disease of the nervous system, may be given by preference, potassium iodid in doses of 20 to 60 grains (1.30 to 4.00) three times a day, beginning with small doses and gradually increasing the dose. In cases of gumma of the skin or subcutaneous tissue, corrosive sublimate should be given hypodermically and at the same time potassium iodid should be given internally in doses of 20 grains each (1.30)

The best local application under these conditions when ulceration has not taken place, is the blue ointment, with gentle pressure made by means of a bandage properly applied. If ulceration should take place the author recommends the following *ointment*:

℞. Cerati resinæ co.			
Ung. iodoformi, āā	ʒii	8	
Balsami Peru	ʒi	4	
Unguenti petrolati q. s. ad	℥i	30	

M. Ft. unguentum. Sig.: Apply locally.

Affections of the mucous membranes should be treated locally precisely as in the secondary period. If deep ulceration exists the iodids should be given in large doses. The proper care must be taken to keep the ulcer clean, and for this purpose he recommends Dobell's solution, followed by a local application of silver nitrate and this followed by a spray, as follows:

℞. Thymol	gr. iss		09
Menthol			
Camphoræ, āā	gr. v		30
Liq. petrolati	f℥i	30	

M. Sig.: To be used as a spray in the atomizer.

Benefit is derived from touching the ulcers with the tincture of iodin and the use of a gargle of the infusion of marshmallow. When the tertiary syphilis affects the tendons or their sheaths prolonged treatment is necessary. Locally the tincture of iodin is recommended, followed later by the following ointment:

℞. Ichthyoli	gr. viii		50
Unguenti hydrargi			
Unguenti belladonnæ, āā	ʒiii	12	
Unguenti petrolati	ʒii	8	

M. Ft. unguentum. Sig.: Apply locally.

Syphilis involving the brain, spinal cord and special nerves, mercury and the iodid should both be employed, combined with suitable tonics.

To aid digestion and promote constructive metamorphosis, Wilson recommends the following pill:

℞. Acidi arsenosi			
Strych. sulphatis			
Auri et sodii chloridi, āā	gr. i		06
Pepsini	gr. xl	2	65

M. Ft. pil. No. xx. Sig.: One after each meal.

The gold and strychnia should be continued for not less than six months. Iron should be added, if necessary.

In the treatment of hereditary syphilis, according to some authorities, the treatment should not be started until symptoms manifest themselves. Others state that a healthy child of a syphilitic father requires no treatment; if the mother was previously syphilitic, but has been free from all symptoms during the period of pregnancy, the child requires no treatment, but if the mother has recently been syphilitic, especially if symptoms of syphilis have been present during pregnancy, the child should receive treatment without delay. Wilson recommends the mercurial inunction as the best and most reliable treatment. Two drams (8.00) of the ointment may be spread on a piece of muslin or lint and applied to the child's body as a belly-band. This band should reach from the axilla to the groin and allowed to remain in place for three days, when it should be removed and the child's body gently washed with soap and water, followed by another application of the ointment. In this way trouble rarely arises. He speaks of mercury with chalk as a good preparation, given in doses of grain 1/12 each (.005), three times a day, by dropping it on the infant's tongue.

Corrosive sublimate in doses of grain 1/150 each (.0004) is also recommended, but is as a rule too irritating to the intestinal canal to be used for any length of time. The tannate of mercury is frequently of service, and this preparation is, as a rule, well borne by children, administered in milk. If marked *tertiary symptoms arise*, potassium iodid should be given in doses of from grain ½ (.03) to grain 1 (.06), in conjunction with the mercury.

Taylor and Bumstead recommend the following combination:

℞. Hydrarg. iodidi rubri	gr. i		06
Potassii iodidi	ʒiv	15	
Syr. sarsap. comp.			
Aquæ, āā	f℥ii	60	

M. Sig.: Five drops morning and evening for a child one month old, increasing the dose one drop every five days. If the child is over 5 years of age, one teaspoonful may be given three times a day.

Spartein.

In an abstract in the *Ohio State Med. Jour.*, Petty states that disappointment in the results obtained from the administration of spartein is due to the insufficient dosage. Most authorities recommend doses of grain 1/6 to 1/3 (.01 to .02) each. He states that the dose hypodermically should be 1½ grains (.09) and not less than 2 grains (.12) by the mouth can be relied on. Like quinin, it is regarded by Petty as nontoxic, and also its effects are definite. He regards it as the ideal heart tonic, decreasing the frequency and increasing the force of the heart's action like digitalis, but at the same time it relieves the burden of the heart by reducing the arterial tension through dilatation of the superficial and deep capillaries. It thus acts as a very efficient diuretic. Its effect lasts for six to twelve hours after administration. He recommends it in the treatment of irregular heart action, given in 2-grain doses (.12) by the mouth and repeated once in two or three hours, and then not oftener than once in four to six hours. In considering its action as a dilator of arterioles and as a heart tonic, thus allowing more oxygen in the lungs and in producing diuresis, Petty regards this preparation as of great service in cardiac failure of pneumonia.

Incompatibilities of Some of the Newer Remedies.

In the report of the committee on newer remedies of the New York State Pharmaceutical Association, according to the *Pharm. Record*, the task of avoiding incompatibilities in the use of the newer remedies of synthetic origin is becoming greater with the increasing number of these preparations. In this connection it is stated that a great many physicians are inclined to prescribe a large number of these preparations in wafers. Many of these preparations are unsuitable for prescribing in wafer form because they attract moisture, which softens the wafers. Among these are mentioned sodium bromid, calcium chlorid, strontium chlorid, chloral, the glycerophosphates, piperazin and the dry vegetable extracts. Iodids should not be prescribed in wafer form, as they decompose or change color.

The fact is also mentioned that many solid preparations when combined produce a liquid, as, for instance, camphor combined with naphthol makes a liquid.

Antipyrin and sodium salicylate when combined give rise to a semi-liquid substance. Antipyrin when combined with chloral gives rise to an oily liquid and similarly when combined with betanaphthol, salol, resorcin, phenol, pyrogallol, thymol or urethane.

Acetanilid is incompatible with chloral, thymol, resorcin or menthol.

Betanaphthol is incompatible with antipyrin, camphor, menthol, phenol or urethane.

Camphor monobromid is incompatible with chloral, phenol, salol and thymol. Camphor should not be combined with betanaphthol, chloral, phenol, pyrogallol, resorcin, salol, thymol or urethane.

Chloral is not compatible with acetanilid, camphor, camphor bromid, menthol phenacetin, phenol, salol, thymol or urethane.

Menthol can not be mixed with naphthol, pyrogallol, resorcin, salol, thymol or urethane.

Sodium salicylate should never be combined with antipyrin and phenol.

Phenacetin is incompatible with naphthol, chloral and phenol. While phenol decomposes antipyrin, naphthol, camphor, chloral, menthol, sodium salicylate, pyrogallol, resorcin, salol, thymol and urethane.

Pyrogallol is incompatible with antipyrin, camphor, menthol and phenol.

Resorcin, according to these reports, forms new compounds with acetanilid, camphor monobromid, naphthol, menthol, phenol and urethane.

Salol shows some chemical change with *antipyrin*, camphor, camphor bromid, chloral, phenacetin, pyrogallol and thymol.

Thymol is incompatible with acetanilid, antipyrin and camphor; also with chloral. menthol, phenol. salol and urethane. · Urethane shows changes with antipyrin, naphthol. camphor, chloral, phenol, pyrogallol, resorcin, salicylic acid. salol and thymol.

The report also speaks of the great care necessary in preparing mixtures of syrups containing acacia with certain phenol derivatives, as incompatibilities are liable to occur as the result of the presence of an oxidizing ferment in the gum, which may produce chemical changes by producing either a precipitation or at least a change in color as syrup of acacia gives a blue color to the resin of guaiac; a somewhat pinkish color with phenol. a grayish color with betanaphthol, a yellowish-brown color with pyrocatechin; and a deposit of crystals of oxymorphin with morphin hydrochlorid.

Syrup of acacia, it must be remembered, is also incompatible with eserin. adrenalin, syrup of tar and liquid preparations of aloes.

Medicolegal

Admissible Evidence as to Value of Physician's Services.

The Supreme Court of Colorado says that but one question was presented for determination in the case of Sills vs. Cochems: Is testimony tending to show that plaintiff was busily engaged in the practice of his profession admissible in an action brought by a physician to recover judgment for the value of professional services rendered, where the price to be charged for such services was not agreed on?

It is said that "when an attorney sues on a quantum meruit (as much as he deserved) for professional services, his professional standing is a proper subject of inquiry as affecting the value of his services. And the amount of his professional business may be inquired into, as tending to show his professional standing." Weeks on Attorneys at Law, 681; Phelps vs. Hunt, 40 Conn., 97. Counsel called the court's attention to no case, and it knows of none, wherein it is held that a different rule should obtain in determining the value of a physician's services. The same reasoning which prompts the doctrine as to attorneys seems to warrant its application to physicians.

The value of professional services may depend very considerably on the character and standing of him who performs them. In the first place there are diversities of gifts. The period of time passed in the profession, the experience acquired. degree of skill and the faculty of using professional knowledge make great differences in individuals. The services of some are worth more than the services of others, because they will command more. Should a question arise as to the value of services, in an action brought by a physician to recover fees, where the nature of the services performed makes the possession of certain qualifications to constitute an important element in the value of those services, as in this case where the plaintiff was called because of his peculiar skill as a diagnostician, evidence of professional standing is clearly admissible and is entitled to consideration.

The fact that the plaintiff was extremely busy tended to show his professional standing. and tended to show, in connection with other testimony concerning the length of time he had practiced medicine in that community, his experience, which gave him the requisite knowledge and ability to properly diagnose and prescribe the necessary medicines for diseased persons. If constant practice in the art of his profession renders a practitioner more capable than he otherwise would be. the extent of such a practice is a matter which may be properly inquired into for the purpose of determining the value of the services rendered.

Duty of Injured Person as to Employing Physician.

The Court of Civil Appeals of Texas says. in St. Louis Southwestern Railway Co. vs. Johnson, a personal injury case brought by the latter party. that the jury was instructed to the effect that it was the duty of the plaintiff to exercise that degree of care that an ordinarily prudent person would have exercised under the same or similar circumstances to employ a physician or physicians, and to secure proper treatment for his injuries, and that if he failed in this respect and his injuries were thereby increased that he could not recover for such increased injuries. This charge announced a correct proposition of law.

May Contract Against Future Professional Competition.

The Supreme Court of Tennessee says, in the case of Turner vs. Abbott, that its examination of the authorities has not confirmed the suggestion of counsel that a contract inhibiting future professional competition is not valid. unless at the time the party inhibited has an established practice or professional good will or a mercantile business which may be made the subject of sale. On the contrary, the court finds numerous cases, English and American, where a clerk or employé, teacher or salesman, on entering the service of a tradesman, manufacturer, or professional man, has been bound by a lawful contract not to engage in a competitive business with his employer. In the present case, the defendant was paid for his services as an assistant dentist, at a salary of $100 per month, which was large compensation to a young man who had just graduated, and under the authorities it was perfectly competent for the parties to make a contract that he would not open an office or practice dentistry in competition with the complainant when he ceased to work for the complainant in the town where the latter then was located and its immediate vicinity. The court thinks that this contract was reasonable and not oppressive; nor was it in any way detrimental to the interests of the public. In other words, it holds that such a contract is not in unlawful restraint of trade or against public policy, but is valid and enforceable. It says, besides what is above stated, that the general rule on this subject, deducible from the authorities, is that a contract in general restraint of trade, that is, not to engage in one's trade or profession at any place in the realm, is void as being contrary to public policy; but a contract not to engage in one's business or profession at a particular place. or for a period of time, is not invalid as being contrary to public policy, but such contracts will be upheld and enforced. And in this case the court affirms a decree restraining the defendant from the practice of dentistry in the town in question or its vicinity, in violation of the contract above mentioned.

Death of Minor from Anesthetic Administered for Operation Without Father's Consent.

The Supreme Court of Michigan says that the case of Bakker vs. Welsh and another was brought by a father, after being appointed administrator of the estate of his son who had died on an operating table at a hospital while chloroform was being administered preparatory to the removal of a tumor on his left ear about the size of a dove's egg. The claim was stated to be under what is known by the lawyers and the courts as the "Death Act." The son was 17 years old, and lived with his father on a farm. The record, instead of disclosing want of skill in the operation, showed quite the contrary. The principal point, therefore, presented was: Were the defendants liable in this action because they engaged in this operation without obtaining the consent of the father?

Counsel for the plaintiff were very frank with the court, it says, and stated in brief: "We are unable to aid the court by reference to any decisions in point. We have devoted much time and research to this interesting question, but have been unable to find any decisions of a higher court either supporting or opposing the plaintiff's contention, and we will therefore have to be content by calling the court's attention to such general reasoning as leads us to take the view herein contended for." They then argued at length and with a good deal of force that, as the father is the natural guardian of the child and is entitled to his custody and his services, he can not be deprived of them without his consent. "We contend," they said, "that it is wrong in every sense, except in cases of emergency, for a physician and surgeon to enter on a dangerous operation, or, as in this case, the administration of an anesthetic, conceded to be always accompanied with danger that death may result, without the knowledge and consent of the parent or guardian. It is against public policy and the sacred rights we have in our children that surgeons should take them in charge without our knowledge and send to us a corpse as the first notice or intimation of their relation to the case."

On the part of the defendants it was contended: (1) Consent of the father was unnecessary. (2) The lack of consent was not the cause of the boy's death, hence not actionable. (3) That if it were, the action did not survive under the death act. (4) That the action, if any, was in the father, not in the administrator. But the court does not think it necessary to a disposition of the case to decide all of the defenses interposed by the defendants.

The record, the court says, showed a young fellow almost grown into manhood, who has been for a considerable period of time, while living with his father, afflicted with a tumor. He has attempted, while at home, to have it removed by absorption. It does disappear, but after a time it reappears. He goes up to a large city, and with an aunt and two sisters, all adults, submits to examination, receives some advice, and goes back to his father with an agreement to return later to receive the report of the expert who is to make the microscopic examination. He returns accordingly, and with at least some of his adult relatives arranges to have a surgical operation of a not very dangerous character performed. Preparations are made for its performance. There is nothing in the record to indicate that, if the consent of father had been asked, it would not have been freely given. There is nothing in the record to indicate to the physicians, before entering on the operation, that the father did not approve of his son's going with his aunt and adult sisters, and consulting a physician as to his ailment, and following his advice. The court thinks it would be altogether too harsh a rule to say that under the circumstances disclosed by this record, in a suit under the statute declared on, the defendants should be held liable because they did not obtain the consent of the father to the administration of the anesthetic. Judgment for the defendants affirmed.

5 Septic Infection Through the Fauces. G. A. Leland, Boston.

2. **Artificial Nauheim Baths in Heart Disease.**—The bath employed by Brown is merely a bicarbonate of soda and acid sodium sulphate bath without the chlorids. He says that the cases peculiarly fitted for Nauheim treatment are those in which the heart muscle acts insufficiently, either from dilatation, poor blood supply or arteriosclerosis with changes in the muscle; poisoning, notably tobacco poisoning, and fatty changes of moderate degree. Brown does not believe that the use of resisted *movements* with the Nauheim baths is essential. They are often very tiresome to the patient and are dangerous in bad cases, unless given by a person who understands fully the purposes of them and who realizes that every case is a law in itself. In his experience Brown has found it best to give these exercises an hour or two before the bath, and when this is not possible, a number of hours after the bath. He has found massage in connection with the treatments of advantage, particularly when the temperature of the bath was below 90.

6. **Ataxic Rectum.**—On examining a number of tabetic cases, Martin found that all showed a sensory paralysis of the external sphincter, although considerable power seemed to remain in the internal sphincter. In three cases of tabes another peculiarity was noted, which was that when the finger was withdrawn the anus did not immediately contract, but remained patulous. Martin says that inasmuch as the rectal and vesical symptoms come on early in the course of tabes, a paralyzed external sphincter, with a history of persistent constipation, should suggest to the mind of the examiner the necessity of trying the other reflexes. The addition of bladder disturbances *may be considered* very suggestive of some changes taking place in the spinal cord, interfering with the transmission of voluntary impulses from the brain. The disturbance of the other reflexes, such as the loss of knee jerk, poor station, and impaired papillary reflexes, will frequently clear up the diagnosis.

Martin has found that the treatment of these cases of ataxic constipation is decidedly unsatisfactory. Probably the best results can be obtained by the regular administration of mild laxatives. The patient should be encouraged to make periodic attempts at stool, and should try the effect of massage over the colon and the lower abdomen. The administration of small doses of the alkaloid of the ripe seed of the calabar bean seems to stimulate peristalsis to a certain extent. A morning dose of sodium bicarbonate seems to work well when the case is a mild one. When there is a persistent tendency toward attacks of fecal impaction the patient should take a high colonic injection of cold or cool water in the morning. This is to empty the lower bowel so as to rid the patient of the annoyance of the pressure of feces in the rectum. In addition to the care of the alimentary tract, attention should be paid to the urinary tract, and a constant lookout kept for any symptoms pointing to urinary retention or vesical paralysis.

11. **Treatment of Diabetes Mellitus.**—Hart defines diabetes mellitus as a disease of faulty metabolism characterized by a deficient power of oxidation resulting in the incomplete combustion of the carbohydrates and fats of the food and of the tissues. Hart protests against the belief that urine with its specific gravity of 1020 can not contain sugar. He refers to 50 instances in which the specific gravity was from 1006 to 1018 *in each of which sugar had been demonstrated.* All treatment instituted must be directed toward improving the powers of oxidation. It is Hart's custom to give the patient written instructions for his dietary for each meal for a week, each day cutting off a little more carbohydrate food, until on the seventh day the diet is composed of a definite quantity of fats and proteids only. The diet for this day is as follows and is termed the "standard diet:" Breakfast: 150 c.c. of coffee with two teaspoonfuls of thick, sweet cream, two poached eggs, four slices of bacon, and butter. Dinner (midday): 150 c.c. of clear bouillon; broiled fish with *mayonnaise dressing;* roast beef, 200 grams; spinach or asparagus, salad of lettuce and tomatoes with French dressing, cream cheese, 20 grams; butter; one small cup of black coffee. Supper: Beefsteak, 200 grams; eggs, scrambled, without flour; cup of tea; string beans, lettuce salad with French or mayonnaise dressing. For the next two days the patient continues on the standard diet to which is added an "accessory diet" of 100 grams of wheat bread equally divided between the morning and midday meals. The twenty-four hours' urine is collected and examined. If glucose is present the patient is allowed the standard diet plus a diminished accessory diet, e. g., 80 grams of wheat bread. If the glucose is absent he is given the standard diet plus an increased accessory diet, e. g., 120 grams of wheat bread. A study of the individual case is all important.

14.—A report of this case appeared in The Journal, July 7, 1906, page 37.

20 *An Unrecognized Etiologic Factor in the Summer Diarrheas of Infants. J. L. Walsh, Caseville, Mich.

16. See abstract in The Journal, July 28, 1906, page 301.

17. Relation of Nasal Passages to Eyes and Ears.—Bryant emphasizes the necessity of attending to the first symptoms of nasal and nasopharyngeal obstructions which are so often the causal factor in producing cerebral symptoms, and many diseases of the eye, ear, larynx, chest as well as stomachic and intestinal disorders, and more general disturbances, nervous and reflex conditions.

18. New Axis-Traction Apparatus.—Jacobson's apparatus is composed of a clamp, which attaches to the edge of a table; an outer case, enclosing a worm and gear (which multiply the power); two rods, the lower one telescoping, joined to the clamp by universal joints; a crank-handle for operating the power-producing mechanism; a hand-wheel at the outer end of the telescoping rod for controlling the transit of the outer end of the apparatus through the orbit which it must describe, when in operation, around the universal joints as pivotal points, a steel tape, which may be replaced by another if kinked without taking things apart, and which winds up on a drum on which it is held and around which it is guided by a metal case containing an aperture into which the tape passes and which does not itself revolve; a small axle on which the gear revolves, and a dynamometer, one of the needles of which is pushed along as an index by the needle proper, remaining at the maximum point reached during the operation for later reference. The needle is true to the scale, whether traveling up or down. The apparatus is made chiefly of an aluminum composition, and weighs about five pounds. This instrument enables the accoucheur to employ measured, steady and precise axis-traction, with a minimum of force and no expenditure of physical energy on his part.

19. Results from Bloodless Reduction of Congenital Hip Dislocation.—Stern reports statistics, gathered from operators scattered all over the world, which very nearly agree with those as first given out by Lorenz as his own experience. The number of hips reported as successfully operated on since 1900 is 2,593. Ideal results, restitutiones completæ, 48.98 per cent.; anatomic restitutions, 41.76 per cent., 1,084; excellent functional results, 7.22 per cent., 187. Good function from transpositions, 39.98 per cent., 1,036. Failure, redislocation, band function, 12.10 per cent., 314. The discrepancy between failures and good results (about 1 per cent.) is due to inaccuracy of many of the reports. Individual operators have had far better results. These latter results will and must be attained through careful and painstaking work, combined with increasing experience and advanced methods.

20. Unrecognized Etiologic Factor in Summer Diarrheas of Infants.—Walsh calls attention to the cathartic property in the grasses which form the food of so many cows from spring to autumn. This property disappears when the grass is dried in the form of hay. The mortality curve follows the life of this type of vegetation, reaching its maximum in July, then gradually declining. Infants get the full physiologic effects and often the toxic effects of the aperient properties in the milk from the grass-fed cows. From October to May there is almost none of this diarrheal tendency apparent. Sterilization does not destroy this poison, which is a chemical one. The cow whose milk is used for infants should be kept off of pasture, and should be stall-fed, as in the winter. The chemistry of the grasses, Walsh states, offers a comparatively new field for study.

25. Construction of a New Vagina.—The patient on whom Brothers performed this operation was 21 years of age. The vagina was represented by a quasi-mucous membrane diaphragm, which could be depressed to a distance of a little more than an inch. Careful and repeated examinations failed to discover any distinct evidence of uterus, tubes or ovaries. Beginning just below the meatus urethra, the incision was carried in a circular manner across to the labium minor, down to the perineum and up on the opposite side to the starting point. This circle of quasi-mucous membrane was dissected away in part at its circumference and presented the firmest attachment to the urethra and bladder with lesser adhesions to the lateral regions and rectum. Neither catheter in the bladder nor finger in the rectum was deemed necessary at any stage of the operation. Several bleeding points at the sides were readily controlled by ligatures or torsion. With Sims' glass dilator (1¼ x 4 inches) the diaphragm was firmly pressed against, so that, by dint of snipping in the surrounding connective tissue and considerable pressure against the dilator, the saucer of mucosa was pushed upward to the full length of the dilator, leaving a cylindrical gap of raw tissue below it. While the dilator was kept under tension and pressed firmly against the vaginal vault, an assistant secured Thiersch skin grafts from the inner side of the patient's thigh, and these were placed over the raw surface by tilting the dilator in different directions. At the completion of the operation the dilator was surrounded at its vulvar end with gauze and retained in position under tension by means of long strips of adhesive plaster secured to the buttock and abdomen to prevent the disarrangement of the grafts. A permanent catheter was left in the bladder and the bowels were kept constipated during five or six days.

At the end of this time the dilator was removed, when it was found that a ring of grafts had become adherent within the vaginal canal to a depth varying between ½ inch and ¾ inch. The mucous membrane at the vault looked normal, but there was a raw gap between the two. Suggestions to repeat the grafting over this area were met with refusal on the part of the patient, especially as there seemed to be some prospect of the gap being gradually covered over by the growth of the new skin. The patient was kept in the hospital for a month, the vaginal canal was kept patent by means of a glass dilator which measured 1⅛ x 4 inches. This was kept in place by a stem perforating a cork closing up the open end of the glass dilator. Through the stem two rubber tubes passed antero-posteriorly and were secured to an abdominal belt on the principle of a McIntosh uterine supporter. This the patient wore with perfect comfort, night and day, and she left the hospital with instructions to keep on wearing it during a protracted period of time.

When examined at this time, two fingers easily passed in to a depth of four inches, and the result was regarded as very encouraging. There was not much progress in the extension of the new skin upward, so that she was advised to return to the hospital and have the raw surface still present covered with grafts. The posterior vaginal surface presented an area of one inch in depth covered by the new skin and two fingers passed readily to a depth of four inches. The vaginal granulating surface was thoroughly curetted and temporarily packed with gauze to check the bleeding. A cylinder had been prepared in the following manner: A glass dilator measuring ½ inch in diameter and 3 inches in length was carefully and smoothly covered with iodoform bandage, until its diameter measured one inch. Over this a thin rubber pouch was snugly drawn and then perforated at numerous points so as to permit the absorption of discharges. On this cylinder grafts of thin skin, secured by a razor from the left thigh, were placed with the raw surface exposed and secured by means of fine catgut. Excepting the two extremities of the cylinder, the entire surface was thus covered over with new skin. The vagina was then thoroughly exposed (after removing the gauze) by means of three deep and narrow-bladed retractors, and the graft-covered plug was introduced. By carefully withdrawing each retractor, exerting pressure centrifugally during the process, the plug was left in the canal with the raw surfaces of the grafts in intimate juxtaposition with the raw vaginal wall. A self-retaining catheter in the bladder and plaster strips retaining the gauze-covered plug in situ completed the operation. The bowels were kept confined with opiates and the patient rigidly maintained the horizontal decubitus during seven days.

At the end of this time the plug was removed and, with the exception of a small area in the left side of the vaginal floor, the entire canal was covered with smooth epithelium. The retention catheter was removed, the bowels were moved and a glass plug (three inches in depth) was secured in place with the McIntosh supporting apparatus. No attempt was made to use a longer or wider tube for fear of disturbing the grafts, some of which had loose ends. One year after the first intervention the patient stated that intercourse had been maintained several times weekly to the complete satisfaction of both parties.

26. **Artificial Renal Colic as Means of Diagnosis.**—Hutchins found that the ability to reproduce, mechanically or otherwise, the pain of which a patient complains is always a most valuable aid in diagnosis. A definite and typical kidney pain (renal colic) can be produced in every instance by forcibly distending the pelvis of the kidney with a bland fluid. In a large majority of cases (98 per cent. in his series), patients are able accurately to differentiate renal pain caused by the method described above, from pains from other causes. By this method a diagnosis can frequently be made in a class of cases, as yet undifferentiated by the medical profession and in which the symptoms are vague and indefinite. Accurate measurements of the amount of dilatation of the pelvis of the kidney may be made with the instrument used, and by this means valuable data are obtained.

The 100 cases studied are divided into four groups: 1. Normal kidney pain produced. Not that pain of which the patient complained. Disease of the kidney ruled out. 2. Kidney pain reproduced. Same pain as that of which the patient complained. Diagnosis of renal or ureteral disease confirmed. 3. Dilated pelvis of kidney. Stricture of ureter. 4. Doubtful cases and failures. Group 1 includes 23 cases. In all the cases, typical kidney pain was produced by the injection of fluid into the kidney pelvis. This pain had a definite location in the superior lumbar triangle. In no case, however, did the pain produced correspond in any particular with the pain of which the patient had previously complained, and disease of the kidney, due to any cause which might lead to permanent or intermittent dilatation of the kidney pelvis, was ruled out. The diagnosis was confirmed later at operation. Group 2 includes 50 cases. In all these cases typical kidney pain or pain referable to the kidney was reproduced and was at once recognized by the patient as the pain of which they had complained and for the relief of which they had entered the hospital. In 35 cases, 25 right and 10 left, the kidney was found to be movable and was suspended. In 8 cases, 4 right and 4 left, the kidney was movable, but operation was refused. In 2 cases, 1 right and 1 left, treatment by bandage was advised. In 3 cases nephrotomy was performed with relief of symptoms. The uterus was suspended in one case and the apendix removed in one case, neither operation affording any relief from the pain.

Group 3 includes 17 cases. In 10 of these cases no operation on the kidneys was performed; pregnancy was a contraindication in one; in another the disease was bilateral, and in a third the patient passed a stone spontaneously. Seven patients refused operation. Of the remaining 7 cases, the kidneys were suspended and the renal pelves folded in one; the stomach, liver and kidneys were suspended in another; stone was removed from the ureter in 2; the ureter was retransplanted into the bladder in one; stricture of the ureter was freed in one; and the kidney was removed in one case. Group 4 includes 10 cases. These cases indicate the limitations of this method of diagnosis. In 6 cases the answers of the patients were so indefinite or the location of the pain produced was so vague that a positive diagnosis could not be made. In 3 cases the same pain was reproduced and its location was fairly definite, and yet in one omental adhesions were found, in another gallstones, and in the third no disease of the kidney was detected. These three cases are regarded as failures. Three of the patients had had previous operations for the relief of pain, but without beneficial result. In one case there was present a large notched tumor of the right flank, supposed to be sarcoma of the kidney. Injection caused pain in this tumor. At autopsy the tumor was found to be of hepatic origin, but closely associated with the right kidney. Pain was easily referred to the tumor by the patient.

31. **Uterine Wall Operation for Anteflexion of Cervix.**—The steps in Coffey's operation are: First, pull down the cervix and uterus with bullet forceps or double tenaculum. Second, insert a cat-claw tenaculum, protrude the fangs and pull the uterus down as far as possible. Third, incise the vaginal mucous membrane at the back of the cervix and dissect up the peritoneum on the posterior surface of the uterus far enough to excise the wedge. Fourth, close the V-shaped incision with strong three-weeks' catgut sutures.

33. **Large Gelatinous Tumor of Ovary.**—Smith reports the case of a woman, aged 54, who complained of a large abdominal tumor, which she had first noticed about a year previously. The abdomen was distended to double the size of a full-time pregnancy by an ovarian cyst, which did not, however, give the usual wave on percussion. The tumor interfered with her breathing so much that for the last six months she had been unable to lie down at night. At the operation the tumor was found to be adherent to the entire abdominal wall in front, but it was easily separated by the hand. The pedicle, which was four inches wide, was hemmed so as not to leave any raw surfaces for the intestine to adhere to. About a quart of free jelly was then removed from the abdominal cavity, but whether this had come out of the small trocar hole made twenty-four hours previously, or whether it came from a rupture of the cyst wall at the back, Smith was unable to say. It appeared as though it had been there for a long time. The contents of the cyst were not like ordinary colloid viscous material, but were more like jelly.

34. **Studies in Absorption.**—Buxton and Torrey investigated the methods by which the animal organism disposes of foreign substances in suspension, e. g., bacteria introduced into the

abdominal cavity. In the case of lampblack some of the particles are taken up by the phagocytes, while others quickly reach the organs, especially the liver and spleen. In the case of typhoid bacilli there may occur an explosive destruction; if destruction is more gradual, large numbers of bacilli make their way into the circulation and are deposited in various organs, especially the liver. There seems to be an immediate rush of particles toward the lymphatics of the diaphragm, whence they pass into the lymph trunks of the anterior mediastinum and then quickly reach the circulation. In time phagocytosis takes place, but at first the particles are free. Another channel of departure from the peritoneum is the omentum. Particles and phagocytic cells become entangled in the fibrinous deposits on its surface. In rabbits especially are typhoid bacilli found on the surfaces of the omentum. Rapid destruction is associated with accumulations of polynuclears, but in general the authors emphasize the part played by mononuclear cells as phagocytes.

42. **Blastomycosis.**—Bowen and Wolbach report a case of blastomycosis in which there was great hyperplasia of the epidermis, minute abscesses surrounded by epithelium, and chronic inflammatory changes in the corium. The organisms were present only in small numbers. Successful cultures were made. The organisms grew on all ordinary media, and best at a temperature slightly above that of the room. The addition of sugars did not materially influence the rate of growth, and there was no marked fermentative action. Inoculation experiments were made with pure cultures on rabbits, guinea-pigs and white mice. The last mentioned were the most susceptible, the alveoli of the lungs being filled with large cells and organisms.

44. **Operative Treatment of Varicose Veins.**—Miller presents the results of treatment of varicose veins of the leg as practiced in Johns Hopkins Hospital. Some of the cases were followed ten years or more. Miller claims that varicose veins of the leg are not an incident of senility; the condition is rather a disease of young and middle-aged individuals, over one-third of the cases appearing before the thirtieth year and two-thirds before the fortieth year. From an etiologic standpoint there are two classes, viz., inflammatory and non-inflammatory. The inflammatory group includes about one-third of all cases, phlebitis occurring as a complication or sequel of pregnancy, postoperative convalescence or an acute infection, among which typhoid fever is the most frequent. The pathology of the non-inflammatory group is obscure. In 128 cases the right and left legs are affected in about equal proportion: over one-half of the cases are bilateral. Trendelenburg's operation cured 78 per cent. in a series of 41 cases; this is about the result generally reported. In the first 4 postoperative years 89 per cent. were cured, from the fifth to the eighth postoperative years but 63 patients were cured; the tendency to recurrence of symptoms increases as the postoperative interval lengthens. Schede's operation cured 33 per cent. in a series of 9 cases. Two patients, two years or less since operation, were both cured. Of seven patients, more than two years since operation, but one was cured.

The tendency to recurrence of symptoms as the postoperative interval lengthens is much greater after a Schede than after a Trendelenburg operation. Division between ligatures of the saphenous vein does not ensure permanent occlusion. The venous stream may be reëstablished in three ways, viz.: Dilatation of anastomoses around the point of division (two cases); formation of varices in the scar (three cases); or end-to-end anastomosis of the ligated stumps (three cases). The Schede operation is followed particularly by anastomosis of ligated stumps. Of 6 patients examined there showed an intact saphenous vein running directly through the scar. Functional restoration of the saphenous vein may be, but is not always, accompanied by recurrence of symptoms. Resection of 8 cm. or more of the saphenous vein at the saphenous opening, made through a generous transverse skin incision, is to be preferred to simple division of the vein. Postoperative pulmonary embolism is rare, but has occurred between the fourth and thirteenth days. The onset is marked by sudden dyspnea, cyanosis, tachycardia and signs of collapse accompanied by rise in temperature; the symptoms may subside rapidly, may persist with the physical signs of pulmonary infarct, or may be followed immediately by sudden death.

55 *An Improved Postoperative Rectal Tube. J. M. Lynch, New York.

55. **Improved Postoperative Rectal Tube.**—The tube used by Lynch is made exactly like Tuttle's tube with the exception of the collar which prevents its slipping into the rectum. Lynch describes his tube as follows: Select a piece of stiff rubber tubing about five inches long and one-half inch in diameter, and a thin rubber condom. Cut a small hole in the blind end of the condom and pass the rubber tube over this hole into the cavity of the condom to the extent of about one-half an inch. Tie the condom around the tube with a piece of thread. Then wrap the tube with gauze or cotton to the thickness desired by the operator for distending the sphincter, covering about three inches of the tube. Reflect the rubber condom over this gauze and tie it around the tube at the point where the gauze ceases, leaving one inch or more of the open end of the condom beyond the end of the tube. Now wrap a small roll of absorbent cotton around the tube at the point where the last thread is tied around the gauze, making this roll large enough to form a prominent collar. Then reflect the loose end of the rubber condom backward over this roll and tie it with a piece of silk thread, or throw around it a small rubber ligature. Thus is formed a complete rubber tube with a flange or collar on its lower end; this collar absolutely prevents the tube from slipping into the rectum and at the same time furnishes an excellent means of producing pressure on any surface around the margin of the anus. Such tubes should always be introduced through a bivalve speculum or with the rectum held open by two flat retractors, in order to prevent any tearing of the parts.

September 1.

1 *Educational number.

1. Educational Number.—In accordance with its custom the *British Medical Journal* devotes this entire issue to a discussion of subjects that have a direct bearing on medical education. The first editorial is on "The Profession of Medicine" and discusses this from the standpoint of what the profession has to offer a physician socially, intellectually and commercially. The second editorial, entitled "The Portals of the Profession," considers the question of the degree, the choice of a medical school, and the cost of a medical education. The regulations of the general medical council, preliminary, scholastic, etc., are also considered. Other topics mentioned more or less fully are the English medical corporations, the universities and colleges of England, Scotland and Ireland; the London and provincial clinical hospitals; the medical education of women; postgraduate study; tropical medicine; preventive medicine; degrees for practitioners; dental surgery, and the public service.

4. Improved Method of Putting Up Fractured Clavicles.—This apparatus has three parts: a shoulder-piece—practically half of a short waistcoat—an elbow piece, and webbing to draw back the upper arm. All are interchangeable. The first two are made of jean, and the webbing is similar to that used for babies' binders. First the shoulder-piece is fitted on the uninjured side, taking care that the loop to support the hand comes in front; a pad is then placed in the axilla, and the arm-piece is tied on round the arm as close up to the axilla as possible, the two free tapes at the end being loosely tied to the lower two tapes on the back of the shoulder-piece; lastly, the elbow-piece is put on, the two tapes behind being tied to the upper two on the back of the shoulder-piece, while in front, the arm having been placed in the usual completely flexed position, with the hand well up on the whole shoulder, the loop is buttoned over the wrist, the upper tape is passed through the small loop opposite to it on the elbow-piece, and tied to the uppermost one on the shoulder-piece; the adjustment of the last two pairs of tapes is obvious. The arm on the injured side is fixed in good position and all that now remains is to tighten up the tapes. The appliance is clean; there is no risk of dermatitis; it is a great economy of time for the surgeon, for the retying of a tape or two is much more quickly done than the application of much strapping, and also, if the patient lives at a distance, any intelligent attendant can soon learn to adjust any tapes which may work loose.

6. Treatment of Asphyxia Neonatorum.—Sheill describes his method of treating a typical case of asphyxia as follows: The child born, its cord is ligated and cut, and its legs wiped dry. Suspended by its legs, the mucus or other matter is removed from its air passages by means of damp cloths and by the mucus evacuator devised by him for that purpose. Next, the child is rapidly transferred to a large bath containing four inches of water at about 110 F. Into this it is placed supine, a rolled towel beneath its shoulders as in Sylvester's original description, so that only its head and face are above water; a small clip forceps is placed on its tongue and allowed to hang to one side, using the angle of the child's mouth as a fulcrum to draw the tongue forward and to keep it there. Counter-traction is made by the nurse or other assistant on the infant's feet, while the operator performs the typical Sylvester method of artificial respiration. Meanwhile the following solution is injected subcutaneously over the deltoid muscle:

Standardized tincture of belladonna...	gr. i	066
Strychnin	gr. 1/100	00066
Whisky	m. x	66

This injection usually gives a noticeably beneficial result in about three and a half minutes, and the dose may be repeated in fifteen minutes, if required. Now an ordinary enema syringe is dropped into the bath and about two ounces of the bath water is gently injected into the child's rectum. At intervals the infant is lifted out of the water and, while suspended by the feet, its spine is well rubbed with whisky or camphor liniment and the mucus evacuator used again. As the child is lifted from the bath, the temperature of which is maintained at the original height, and suspended as before, it may at intervals be slapped, rubbed and blown on with the breath, especially the latter in the face, which tends to stimulate reflexly the respirations. A little later a splash of cold water down the spine, or more effective still, in the face, will probably produce a gasp. Now Sylvester's method, unlike Schultze's, can be timed to act with the respiratory effort of the rescued child; when it gasps like a dying trout, as it is an inspiratory effort, draw up the arms quickly, and if it cries, however freely, compress the thorax to assist its extirpation. Do not use the cold bath, even for a moment, until well into the livid state with a strongly beating heart, otherwise a fatal collapse may result. Should the child, in spite of this combination of methods, fail to be resuscitated, the operator may at any rate feel assured that the best has been done for it.

22. **The Pozzi "Livre d'or."**—The souvenir volume presented to Prof. S. Pozzi on the completion of 20 years of teaching at the Hôpital Broca, is said to mark an epoch in the history of gynecology in France. Pozzi's service was the first in France to assert the independence of gynecology and, in order to show the present standing of the science, Faure describes with minute detail an ordinary abdominal hysterectomy as done to-day in a well-equipped operating-room. The present record is that 95 per cent. of the patients are cured by the intervention, and he thinks we have reached the limit of perfection in our technic. The surgeons of A. D. 2000 will not perform an abdominal hysterectomy any better, he declares, than it is done to-day, although by means of discoveries beyond our ken at present they will not have to perform the operation so frequently as we do. All the articles in this number of the *Revue* are taken from the Pozzi souvenir volume.

23. **Sterility.**—The subtitle of Pinard's article is "What the physician should know and do to be able to treat sterility." He remarks that the percentage of families without children is about the same in various countries, 11.3 per cent. at Paris and 12.8 per cent. at Berlin, for example. The cause of the sterility is in the wife in about 60 per cent., and in the husband in about 40 per cent. Sterility in the female due to congenital external anteflexion is best treated by dilatation with the catheter, repeated two or three times after each menstrual period, and this treatment kept up for months. Pinard has known conception to occur after 9 and 12 months of this treatment. It not only restores the uterus to place, but overcomes the stenosis both of the external and internal os at the same time. In case of non-painful but scanty and irregular menses, after long regularity, he has restored conditions to normal with consecutive pregnancy in hundreds of cases by the simple restriction of the diet to milk alone for a month or so. In case the menses have stopped, with a uterus rather above medium size, the trouble is due to a premature menopause, beyond remedy. When examining the husband, he must never be told that the absence of spermatozoa is permanent. Pinard knows of three men who committed suicide on being told this. Iodid treatment has given good results in some cases of gonorrhea or syphilitic orchitis. In case of impotence, hygiene alone should be applied, but, with malformation of the genital organs, the semen fertile, artificial fecundation may be indicated.

25. **Gynecologic Souvenirs.**—Reverdin writes from his "anecdotage" an interesting sketch of the rise and development of gynecology in France, and of various national and international gatherings of specialists. He particularly comments on the greater confidence and liability of better results when a surgeon is operating in his accustomed environment. An invitation to operate when visiting a clinic away from home should not induce a surgeon to perform an operation, involving risk of life, merely because his vanity has been flattered by the invitation and the deference shown him. He advances this merely as his opinion, but confesses that it is based on several unfortunate personal occurrences. The great benefits of visiting others' clinics and operating-rooms he amply extols, saying that this intercourse with other minds and technics is one of the chief advantages of congresses, and that he does not agree with Mme. de Staël's dictum: "When men are congregated together their ears lengthen out."

26. **Oxygen in Gynecology.**—Thiriar has been experimenting with oxygen in gynecologic affections for a dozen years, and published his first results in 1899. His experience since has confirmed his first assertions and he now proclaims his belief that oxygen is the natural remedy for infection with anaërobes, especially gaseous septicemia, and is the antiseptic of the day. It is also the best means, he says, for preventing and curing septic complications in gynecology, and for treatment of all gynecologic infections. After the vagina has been rinsed he introduces an ordinary vaginal cannula connected by a rubber tube with the tank of oxygen. The cannula is held in place with a T bandage, and with a pad of cotton applied outside. The oxygen is then turned on and is allowed to flow for several hours without further attention. When the cannula is withdrawn a large pad of cotton is applied with a T bandage. The oxygen may be used thus the day before an operation, and resumed a few hours afterward. The oxygen penetrates into every crevice in the vagina and escapes through the cotton pad. Bacteriologic examinations before and after show the efficient bactericidal action of the protracted application of the gas. Preventive, preoperative asepsis of the vagina is easy and certainly obtained by this "méthode oxygénée" as he calls it. In case of an adherent pyosalpinx with contamination of the small pelvis with very virulent pus, after the toilet of the cavity, he introduces two long tubes, with an opening at the tip, sometimes interposing a wick of iodoform

gauze. One of these tubes is connected with the tank of oxygen, the other acts as a siphon, its outer end being in a vessel containing an antiseptic solution. The abdomen is closed as usual, and the oxygen turned on; the bubbles rising in the fluid in the vessel show the force of the current. The outflow of the oxygen sweeps along all the secretions which otherwise might accumulate and serve as nests for bacteria. The secretions are sometimes so abundant that the fluid has to be renewed several times during the day. Since this oxygen treatment has been in constant use, there has not been a single instance of infection of the peritoneum, even when it had been soiled. A number of instructive cases are related, among them that of a woman of 42 with rupture of the uterus during childbirth. The omentum protruded from the vagina, the pulse was thready, 120, respirations 32, temperature 36.6 C. The entire peritoneal cavity was found soiled with meconium, etc., and a fibrinoplastic exudation already coated the intestines. The uterus was torn for 10 cm. and the vagina for 5. After abdominal hysterectomy and the toilet of the region the oxygen and siphon tubes were introduced as far as the pouch of Douglas and the abdomen closed. The oxygen was turned on, the force sending up a bubble at a time, and this was continued for five days. The pulse and respiration soon returned to normal and the temperature never rose above 38 C. The patient was dismissed completely cured in three weeks. The oxygen undoubtedly, Thiriar states, prevents formation of adhesions and restores normal conditions in the parts. When the oxygen is used in an established peritoneal infection, he passes the jet of oxygen over the parts in the same way that furniture is cleaned with compressed air. It breaks up and removes fibrinous deposits, before the continuous flow and siphon are arranged. Several separate tubes and siphons might be used to advantage, he declares, in some cases. In tuberculous peritonitis he evacuates the ascites through a buttonhole incision, and sends a stream of oxygen into the cavity for ten minutes. He then closes the abdomen and awaits with confidence the cure which is certain, he says, to occur in a few days. In infectious gynecologic conditions, metritis, etc., he uses a two-way sound with a gentle flow of oxygen, kept up for two or three days. Even if a little oxygen should get into the circulation this is not so dangerous, he thinks, as some observers have insisted. He has never witnessed any untoward effects from the oxygen method. One patient with hemorrhagic metritis succumbed just as the arrangements were completed, but before the current had been turned on. Reverdin in the preceding article also reports excellent results from the oxygen treatment, without by-effects. [Costa, in Italy, used the oxygen intermittently, as he reported last year, without any satisfactory results.—ED.]

30. **Transperitoneal Operation for Vesicovaginal Fistula.**—Forgue's 5 illustrations show the various phases of the operation which he successfully performed in a case of extensive laceration of the bladder, vagina and cervix in a x-para of 43.

33. **Treatment of Extrauterine Pregnancy Near Term.**—Barnsby's experiences with 5 cases compel him to advocate marsupialization with patient waiting for expulsion of the placenta in all cases of extrauterine pregnancy, with the fetus dead, within 2 months of term. Total extirpation should be reserved for the rare cases of tubal pregnancy in which there are no adhesions between the fetal sac and the adjacent organs. Marsupialization and expectancy, he states, eliminate the danger of hemorrhage, and reduce the chances for infection. The whole intervention is thus extraperitoneal, and the prognosis is good; these advantages, he declares, outweigh the drawbacks of the incomplete operation. In draining, a T tube introduced into the cul-de-sac of Douglas insures the drainage of the lower part of the sac.

34. **Renal Retention of Urine After Vaginal Hysterectomy.**—Legueu has observed 4 cases of this kind, the hypertension of the kidney and the infection occurring apart from any accidental injury of the ureters, that is, without these structures having been clamped.

Semaine Médicale, Paris.

36 (XXVI, No. 34.) *Le présent et l'avenir de la médecine européenne en Chine. L. Legrand.
37 (No. 35.) *La polycythémie splénomégalique. L. Cheinisse.

36. **Prospects of Western Medicine in China.**—Legrand, physician to the Imperial Railroad Company in China, here gives an interesting sketch of the Chinese character in relation to modern medicine. The Chinese do not fear death; they do not think of it; their attitude is constantly heroic before the inevitable. Their sensibilities are not so keen, the capacity of suffering and enjoying is less, they are lazy in body and mind, and penurious, while they are imbued with a sense of the instability of human goods, owing to injustice, revolutions, etc., and they have a profound and atavistic disbelief in a personal future life. Their ideal of earthly happiness is to lie and dream away the hours, and the idea of perpetual rest in the grave is not repelling. The native physicians have a comparatively low position and generally have some other means of support. As absolutely nothing is free in China, not even the food in the prisons, they can not conceive why a physician or surgeon gives free consultations, and they attribute to him every motive but the right one. The medical missionaries in China are looked down on, Legrand adds, and their motives misunderstood for this reason. The Chinese say: "What crime has this foreigner committed that he should be banished from his country and have to come here to tend the sores of the coolies who ridicule him when he has finished? He must be very ignorant and awkward to be reduced to tending the dregs of the people and not even to demand the few pennies that the poorest Chinese doctors would ask for such services." Some of the applicants at his clinic come to steal, others merely to beg, and others just to ridicule the foreigner among themselves. Even if Chinese students become thoroughly trained in medicine, it can be only in the science; they will lack the imaginative, constructive and synthetic faculties which make of the science an art. China will absorb all that can be learned from the Occident in respect to locomotives and cannon, and everything else that will enable it to defend better its traditional civilization against the outside world. Unless there is a complete regeneration, however, both in character and ideas, western medicine will have little chance to spread in China or to take a dignified and remunerative position there. The Chinese have a saying, dating from eleven centuries before our era, that "no one can be called a physician who does not cure six out of every ten patients, for, if only five recover, the patient is as well off without him, as half of all the sick get well without aid."

37. **Polycythemia with Enlarged Spleen.**—Cheinisse analyzes the various communications that have been published on this subject, and draws the clinical picture of the disease much as presented in an editorial in these columns recently (page 510). He remarks in conclusion that, on account of the lack of any specific medication or measures, splenectomy might be justifiable, as advocated by Vaquez and Laubry. Quinin gave encouraging results in Begg and Bullmore's and in Zimlick's cases, and arsenic in Türk's case and in others.

45. **Lumbar Puncture in Tuberculous Meningitis.**—Schlesinger has found that by repeated lumbar puncture it is possible to prevent the appearance of convulsions in tuberculous meningitis. A single puncture may be sufficient in some cases, even in the moribund. He advises it as early as possible, and allows as much cerebrospinal fluid to escape as flows spontaneously. When tubercle bacilli of comparatively attenuated virulence are found in the cerebrospinal fluid, the outcome may possibly prove favorable; 5 cases have been published in which recovery occurred, although tubercle bacilli were found in the cerebrospinal fluid. None of his patients recovered, but he has been much impressed with the prompt benefit that followed lumbar puncture.

46. **Three Cases of Tumors Compressing the Spinal Cord.**—Borchardt has had the good fortune to operate in 3 cases of tumors compressing the spinal cord with a successful outcome in each. The findings are illustrated. The symptoms in the first case were atrophic paresis of a segmentary character in the left arm with corresponding anesthesia and the symptom-complex of the Brown-Séquard hemiplegia. The patient was a woman of 33, who complained of pains between the shoulder blades and in the left shoulder for four or five months, with weakness of the left arm and stiffness in the left leg. By the end of the ninth month the contracture and paralysis had increased to complete helplessness. The assumed benign tumor was found, as diagnosed, at the sixth and seventh cervical vertebræ. The results were the gradual subsidence of the symptoms of compression. In the second case the symptoms were more complicated and indicated considerable compression of the spinal cord at the fourth and fifth dorsal vertebræ. The first symptoms had been pains in the legs, abdomen and back, weakness in the right leg, disturbances in micturition, impotence, and paresis. The tumor in this case was soft and extended vertically for 5 cm. with a small projection to the left. The symptoms have gradually subsided to some extent since the recent removal of the tumor, and the patient is now able to walk, although still with a gait suggesting ataxia. The other disturbances have righted themselves. The tumor was exactly in the median line, which accounted for the unusual character of the symptoms. Oppenheim gives an illustration of five tumors removed from the living subject on his diagnosis, and mentions three others which are not represented in the picture. Borchardt operated by laminectomy at a single sitting, and reviews various details and general features of operations affecting the spinal cord, especially the danger of secondary infections. In the first case the operation was followed by obstinate bronchitis, incontinence both of urine and stools, catarrhal cystitis for three weeks, decubitus and severe lancinating pains in the legs, but these gradually subsided and the patient is now so well that she can walk for hours and has entire charge of the housekeeping and garden. She is the wife of a workingman, and refused to consent to the operation for five months after the diagnosis had been made. Convalescence in the second case was disturbed by intensely severe pains in the penis, buttocks, and legs, requiring large doses of morphin, but they subsided spontaneously after a few days. In a third case the tumor was found as diagnosed at the sixth dorsal vertebra and its removal was very tedious, but the incision, 25 cm. long, healed completely by the seventeenth day.

47. **Anatomic Leukemia Without Leukemic Blood.**—Ewald describes a case with autopsy in which the symptoms indicated acute myeloid leukemia running a fatal course in about seven weeks. The patient was a robust man of 37. The autopsy disclosed hyperplasia of the spleen, lymphomatous infiltration of the liver and kidneys, "raspberry jelly" bone marrow, hemorrhages in kidneys and stomach, fatty degeneration of heart with enlargement and pericarditis with adhesion. The microscopic findings also were those of leukemia. At the same time the blood did not present any of the characteristics of leukemia and there were no pains in the bones and no enlargement of the peripheral glands. The lack of the latter and the negative blood findings, as well as the rapidly fatal course of the disease, spoke against splenic anemia, and nothing was found to indicate a septic process.

49. **Passive Congestion Treatment of Gonorrhea.**—Jacoby has been impressed with the favorable influence exerted on gonorrheal processes by the application of an apparatus for suction therapy according to the Bier-Klapp technic. A sound is used that fits into the anterior urethra air-tight and is connected with a rubber bulb. The sound is made with three long, deep grooves, with five comparatively large openings in each groove. In order to bring all parts of the mucosa under the influence of the suction, the sound is turned the second time at right angles to its position at the first sitting. He leaves it in the urethra for from 10 to 15 minutes.

50. **Diagnosis of Gastric Cancer.**—Among the various diagnostic points emphasized in this review is the sudden beginning of the symptoms calling attention to the stomach, in persons previously free from digestive disturbances. In Kuttner's experience the symptoms were generally referred to some error in diet, and the pains and vomiting were assumed at first to be acute and then chronic dyspepsia. In three instances the first symptom was profuse hemorrhage in the stomach. In some cases, however, the affection developed insidiously with merely vague dyspeptic disturbances. He does not believe that there is much danger of the development of cancer on the basis of chronic gastric catarrh. He has encountered only four in his hundreds of cancer cases in which there were evidences of preceding atrophy of the stomach. The second important sign, after the abrupt onset, is the progressive decline of the appetite. Complete anorexia, sometimes actual repugnance for food, especially for meat, is an important and sometimes a very early symptom of cancer. With ulcer the appetite is generally good, and the retention of a good appetite to the last may be exceptionally observed even with cancer. His experience has been that gastric cancer is not restricted to middle age, but is liable to occur earlier, and is frequently incorrectly diagnosed in the young. A history of cancer in the family, especially gastric cancer, or of preceding ulcer or of trauma, affecting the stomach, should be regarded as predisposing factors. Sometimes the patients are unusually pale, probably from occult bleeding, and sometimes there may be loss of weight and strength, but this is not inevitable. He had three patients, working men, who were able to keep at their work until the very last stage of malignant disease. Obstinate itching of the skin has been observed frequently in case of gastric cancer, and he regards it as an important sign, as also putrid smelling eructations accompanying dyspeptic disturbances. It is important, he states, to smell of the stomach tube in dubious cases. A particle of extremely putrid matter may give the clue to an ulcerating cancer. Pain is not characteristic and of not much differential value. The finding of "coffee grounds" in vomit is suspicious. Deficient production of gastric juice has no differential value, but the constant finding of lactic acid justifies the assumption of cancer, although it is not an early sign. He agrees with Glässner that in case of reduction equally in both the lab ferment and pepsin, the tumor may be in the fundus, while if the lab is in approximately normal amounts while the pepsin is reduced, a tumor in the pyloric region may be suspected. Rare instances are known in which the motor function has remained approximately normal nearly to the end. In testing the motor function it is necessary that the conditions should be identical at each test, and it is important that an abundant meal should have been ingested the evening before examination of the fasting stomach. If even minute amounts of blood with pus or the latter alone or with mucus are found in the fasting stomach, the assumption of cancer is almost certain. Blood alone is not so significant, although the constant finding of occult blood has great differential value, especially in cases without retention of stomach contents and with deficient gastric juice. When the gastric juice secretion is normal and there is stagnation, the occult blood findings are unable to decide the question as to ulcer or cancer. The constant absence of blood in stomach content and stools is good presumptive evidence against cancer. Albuminuria was rare in Kuttner's cases of gastric cancer, but the urine generally contained large amounts of indican and of Rosenbach's pigment. The repeated finding of albumosuria and a positive diazo reaction, under some cir-

cumstances, suggest cancer. Another sign is the discovery of amebæ and flagellates in the mucus of the fasting stomach, and also the presence of albumin in the fluid in the fasting stomach according to Salomon's method. Kuttner's extensive experience has confirmed the diagnostic value of this albumin test. Salomon gives fluid food, free from albumin, at noon. In the evening he rinses the stomach clean. The next morning the stomach is rinsed out several times with 400 c.c. of physiologic salt solution, and the albumin content of the rinsing fluid is determined. When the fluid turns flaky at once under the Esbach test or if the Kjeldahl test shows more than from 20 to 25 mg. of nitrogen in 100 c.c. of rinsing water, the suspicion of cancer is justified. It is possible for albumin to be eliminated in the stomach in simple gastritis, but this must be very rare, as Kuttner, Salomon and others have never encountered a case in which much albumin was found in the stomach content. Another sign of cancer is pleuritis on the left side. Kuttner has repeatedly found this pleuritis accompanying cancer in the lesser curvature. Visual inspection of the interior of the stomach and study of the blood are less promising than Roentgen examination. The presence of a cancer is liable to induce abnormal peristalsis, and also to cause the stomach outline to be abnormal at some point or points. The shadow cast by the stomach content also shows extraordinary recesses and projections. In regard to operability, it must be remembered that a small carcinoma may prove to be fully as malignant, if not more so, than the large ones.

51 (IX, No. 11.) *Die Therapie der Larynx-Tuberkulose. R. Imhofer. Review of the literature. (Commenced in No. 6.)
52 (Nos. 15-16.) *Weitere Ergebnisse der Roentgen-Behandlung bei Leukämie und Pseudoleukämie. K. H. Schirmer. Review of the literature.

51. **Treatment of Laryngeal Tuberculosis.**—Imhofer analyzes 253 articles published on the subject of laryngeal tuberculosis between 1900 and 1905. His conclusions are to the effect that at present we are as far removed from the resigned nihilism of former days as from an absolutely certain successful treatment. The first question is to decide whether or not curative or only palliative measures are required for the case in hand. This is decided by the general condition and the state of the lungs. The next step is to apply general treatment, and in this the environment of the patient is of extreme importance. The selection of the proper local treatment for the individual case is also a problem. It may be necessary to vary the caustic and also its mode of application to conform to the individual reaction. It is wise also to interpose occasionally a few days of rest with merely a local anesthetic. It is of the greatest importance after curettement to wait until the operative wound has entirely healed and the success of the intervention is determined before attempting to repeat it. A brief trip to the country sometimes has an excellent effect in the interim. Palliative treatment should be restricted to the minimum necessary to relieve the subjective disturbances.

52. **Roentgen Treatment of Leukemia.**—Schirmer has found 109 articles published in the last two years on the treatment of leukemia and pseudoleukemia with the Roentgen rays. Most of the writers used fractional doses and numerous sittings, but the Vienna school advocates a single complete sitting. Holzknecht of Vienna has had the most extensive experience with Roentgen treatment of leukemia, but he has not yet published his report. It seems to be the general opinion that in Roentgen treatment we possess a generally promptly efficient means to improve materially even severe cases of mixed-cell leukemia. Recurrences are generally amenable to the same treatment, but it seems natural to suppose that as the disease progresses it will prove more refractory to the rays. Schütze has reported a unique case in which there was no recurrence for three and a half years after the exposures. The results are less constant in lymphatic leukemia; 7 cases in which it proved successful are balanced by 3 in which no benefit was derived. It is certainly worth a trial, although it must not be forgotten that remissions are not infrequent in lymphatic leukemia. Besides the true remissions there are also pseudo-remissions induced by lytic processes affecting the atypical, immature forms of leucocytes. In pseudo-leukemia and in Hodgkin's and Banti's diseases, favorable results have been reported by various writers in 11 cases of pseudo-leukemia and in 4 of Hodgkin's disease. Liebermeister reports that a woman of 60 reacted to the exposure with weak heart action; the glands in the neck became still larger and death soon followed. Krause observed ulceration in the neck after exposures in a case of pseudo-leukemia. Quadrone reports that pleuritis with effusion developed in 2 patients with lymphatic pseudoleukemia after Roentgen treatment. In 2 cases of symmetrical enlargement of the parotid gland, the swelling subsided under the rays, although recurrence was soon observed in one case. No results were apparent in Krause's 3 cases of splenic anemia and 2 of enlargement of the spleen of unknown origin. Bozzolo insists on the favorable action of the rays in Banti's disease, and recently they have been applied in treatment of lymphomata of tuberculous nature. The theoretical views in regard to the action of the rays are conflicting. When the results are negative in case of lymphatic leukemia and pseudo-leukemia, the reason may be an unusually rapid regeneration of the blood cells.

53. **Lysol Poisoning.**—Blumenthal mentions that about 100 cases of lysol poisoning come under treatment in Berlin every year. Even when the stomach is not rinsed out for two or three hours afterward, it is yet possible to evacuate a large proportion of the lysol. His postmortem findings and chemical studies have demonstrated that lysol is not a poison for the blood, but acts mostly on the cell, especially on the liver cells. The stomach should be rinsed until there is no longer trace of lysol. It has been found sometimes that even after all trace of the lysol has disappeared, further rinsing a couple of hours later will show more lysol, probably due to elimination into the stomach with consecutive reabsorption in the intestines unless removed by rinsing the stomach. No antidote is known to date, he states, but if the patient survives the first twenty-four hours he is liable to recover and to be free from serious after-effects. Blumenthal believes that an antitoxin is formed to protect against the lysol, and that glycuronic acid —which is excreted in large amounts—represents the antitoxin, or at least has some share in the neutralizing process. The lysol has an affinity for fat, and consequently penetrates into the cell through the lipoid substance. The cell then reacts to this invasion by producing sulphates and glycuronic acid out of its own supply of albumin and carbohydrates. They are produced in excess and act on the intruding poison like a true antitoxin, although, unlike the true Ehrlich antitoxins, they do not pass into the blood to any extent.

57. **To Retain Anterior Wall of Sinus in Frontal Sinusitis.**—Ritter opens up the frontal sinus through the wall of the orbit and bores a passage slanting from the highest point downward into the sinus, which allows curettement and drainage with a long strip of gauze.

60. **Secretion of Gastric Juice.**—Bickel's research has demonstrated beyond question that the most various stimuli affecting the organs of taste or smell are capable of inducing a secretion of gastric juice when the stomach mucosa is resting

or of increasing an already existing secretion This same effect follows stimulation of taste or smell whether the sensations are agreeable or disagreeable The quality of the gastric juice secreted seems to be constantly about the same in man, but the quantity secreted varies widely at different times and with different stimuli His experiments were made on a young woman with a fistula into the stomach, after esophagotomy. The findings speak most decidedly, he thinks, against the assumption of "hyperchlorhydria" as an increase in the proportion of acid He assumes that the gastric juice represents about a constant substance, and that the symptoms attributed to hyperchlorhydria are in reality the effect of the quantity of the secretion and of motor phenomena, instead of any change in the composition of the gastric juice.

61 **Treatment of Chronic Dysentery.**—The 3 cases of chronic dysentery described by Meyer came under treatment in Dresden and suggest the importance of examining for amebæ even when there is no history of a residence in the tropics. They also suggest the advisability of tentative treatment with ipecac and iodoform enemas even when amebæ are not found at first in the stools, after exclusion of intestinal tuberculosis, gastric or pancreatic achylia, fermentative dyspepsia or other cause for chronic diarrhea He was much gratified with the results of treatment with ipecac given with a few drops of opium and peppermint, supplemented by high rectal injections of about 250 c c of a solution of 5 gm. iodoform in 1,000 gm. of mucilage of gum arabic, given in the knee-elbow position under high pressure, with an attempt afterward to massage it up into the colon The iodoform is left in the intestines for about ten minutes and the larger part is then washed out with two enemas of water. If the amebæ are ensconced in the appendix it may be necessary to remove that structure before the affection can be cured

63 **Roentgen Treatment of Exophthalmic Goiter.**—Sklodowski reports a case of exophthalmic goiter in a girl of 15 of six months' duration Roentgen treatment was applied, half of the thyroid gland being exposed at a distance of 20 cm. for ten minutes at a time The improvement after less than a month of this treatment was striking. The girl gained over 13 kilos in weight in 16 weeks and the sweats and nervous condition were improved although the other symptoms persist.

64 **Tendency to Tetany Due to Lime in Infants' Food.**—Stoeltzner has been continuing Finkelstein's research on the constituents of cow's milk to find which is responsible for what he calls "spasmophilia." He thinks that the phenomena observed incriminate the lime in cow's milk as the cause of the tendency to tetany. These conclusions, he states, harmonize with the results of recent physiologic research on the lime salts, such, for instance, as the fact that the presence of small amounts of calcium salts is indispensable for success in the experiments with the isolated still living heart. The pulsations of the heart cease unless the fluid pumped through it contains the appropriate calcium salts.

65 **Intestinal Absorption of Antitoxin**—Romer and Much relate recent research which confirms their previous assertions in regard to the permeability of the intestinal wall for antitoxin during the first few days after birth. This permeability grew less as the animals (calves) increased in size. Their experiments further showed that the intestinal absorption of albumin from horse serum, thus a heterologous albumin, proceeded in like manner. The absorption was much greater when the antitoxin was ingested in the milk of the immunized mother than when the milk was given from the bottle after addition of antitoxin in the form of antitoxic horse serum. The further fact was established that in cows treated with horse antitoxin the antitoxin was modified in some way so that as it passed into the milk it acquired the properties of cow antitoxin, and was absorbed in the digestive tract of the calf as perfectly as actual cow antitoxin.

68. **The Cerebrospinal Fluid in Congenital Syphilis.**—Tobler reports that in 14 cases of congenital syphilis pronounced lymphocytosis was evident in the cerebrospinal fluid in 12 of the infants. The findings were negative in one case and dubious in another. The proportion of albumin was abnormally high in 5 out of the 7 cases These characteristic findings in the cerebrospinal fluid were manifest at a period before any other symptoms suggested the positive presence of syphilis. The syphilitic affection of the parents was the only clue to syphilis in the child in some cases, but the characteristic findings in the spinal fluid were soon followed by other signs of the inherited disease. The brain and spinal cord in some of these children when examined later showed unmistakable evidences of an inflammatory meningitic process with effusion.

71. **Scarlet Fever Nephritis in Families.**—Spieler observed 14 instances in which 2 members of the same family had nephritis as a complication of scarlet fever, and 3 instances in which more than 2 members of the family were affected. His total experience includes 83 families, with 186 children with scarlet fever; of this number 35 families, with 83 children, presented 51 cases of nephritis. He thinks that in certain families an unmistakable predisposition to nephritis exists.

73. **Dietetic Treatment of Exophthalmic Goiter.**—Alt asserts that a diet adapted to the special needs of the metabolism in exophthalmic goiter is capable of brilliantly successful results, as he has demonstrated by his own experience. Two years ago he reported extremely favorable results with dietetic treatment of myxedema, and his experience with exophthalmic goiter has been fully as remarkable. The internal oxidations are augmented in the latter, the metabolism accelerated, as in case of artificial hyperthyroidization. Some of the components of the general transformation and interchanges of matter are abnormally weak, and some are unusually strong. In the idiocy of myxedema it was found that the patients assimilated only a very small amount of the phosphorus ingested in their food. Under thyroid treatment their power of assimilating phosphorus increased, and administration of phosphorus combined with an albumin preparation gave excellent results. In 12 cases of exophthalmic goiter considerable insufficiency on the part of the kidneys was revealed by functional tests with salt. Most of the patients had more or less edema. By putting them on a diet free from salt a balance was finally established between the amount of salt ingested and that eliminated. The edema vanished and the heart action at once improved, the pulse rate approximated normal and the subjective disturbances subsided. Illustrations of patients "before and after" show the remarkable benefit derived in four instances, and similar illustrations of patients with myxedema confirm the advantages of scientific dietetic treatment. Alt declares that every sanitarium for nervous and mental affections should have a well-equipped laboratory for research on the metabolism as an indispensable adjunct. In his cases of exophthalmic goiter the demand for calories was strikingly high, two or three times the normal demands, or even more. Intestinal absorption was also good, even in the cases with unusually active peristalsis and three or five stools a day. One patient required 100 calories per kilo of body weight and thrived on them. In this and some other cases phosphorus was taken up in the intestines with unusual completeness and was eliminated in the urine in abnormally large amounts. This would soon have led to phosphorus starvation in the organism and deterioration of the bones if phosphorus had not been supplied from without in sufficient quantities. These observations on the augmented output of phosphorus in exophthalmic goiter throw light on the cases which have been reported by Latzko and others in which exophthalmic goiter became complicated with osteomalacia. The diet in the cases reported by Alt was distinguished by reduction of the amount of salt, not more than 4 gm. a day being allowed, the ingestion of fluids also being restricted; the amount of carbohydrates was also reduced in proportion to the low degree of tolerance, and the food was planned to supply large amounts of calories, in the form of albumin and fat, for which milk, cream, unsalted butter, rice, meat, eggs and fish were the main reliance, with milk first and always. On this diet the patients all gained in weight without the gain being due to retention of water, while all the symptoms of the disease subsided to a remarkable extent, with an unmistakable gain in the functional capacity of the previously insufficient organs. He mentions in conclusion that the exophthalmic goiter in his patients had been preceded by acute articular rheumatism, prolonged grippe or an intestinal affection with icterus, in nearly every instance. The particulars of some of the cases are given in detail with the daily dietary.

82. **Rapid Test for Albumin in Urine.**—Buchner gives an illustration of this simple outfit. It consists merely of two bottles, two test-tubes, the graduated test-tube for the albuminimeter, and a flat piece of cork with a hole in the center to serve as a standard for the albuminimeter. The test is based on the complete coagulation of the albumin in urine, first heated and then treated with nitric acid and a saturated solution of salt. The clear, filtered urine is poured into a test-tube to a mark representing 8 c.c. It is then heated to boiling, and two or three drops of nitric acid are added and 2 c.c. of a saturated solution of table salt. After being well shaken the contents of the tube are poured into the albuminimeter. After an hour's precipitation each c.c. of the deposit of albumin at the bottom of the tube corresponds to 1 per thousand of albumin in the urine. Comparative tests of this technic with Esbach and other tests showed remarkably concordant findings.

84. **Auscultation as an Aid in Diagnosis of Surgical Bone Affections.**—Ludloff expresses surprise that surgeons pay so little heed to the important findings possible with auscultation of the spine, sacrum and pelvis. Crepitation can often be heard and will reveal the cause of mysterious pains in certain cases. In one of the cases described, after fracture of the clavicle, the other complaints of the patient were ascribed to hysteria or simulation and received scant attention for eight years, during which the patient consulted various authorities. Finally auscultation revealed crepitation over the seventh cervical vertebra, and a bony prominence was discovered. A radiogram then disclosed that this vertebra had been fractured, evidently at the same time as the clavicle. In other cases elderly women complained of pains in the region of the sacrum. As palpation and inspection revealed nothing wrong, they were referred to a gynecologist, but he could find nothing to explain the pain, and radioscopy was equally fruitless. Examination with the stethoscope and phonendoscope revealed a distinct grinding and cracking, generally at the junction of the sacrum and vertebræ, the sounds resembling those heard at the knee in case of arthritis deformans. Auscultation of the entire spine then usually revealed a spot where these sounds were heard loudest. Examination of this spot by radioscopy then generally disclosed some small deposit on the joint, a focus of arthritis deformans in the spine. A lesion of this kind is liable to entail not only sacral pains, but lumbar and sacral neuralgia. When the focus is at the emerging point of the sciatic nerve it is liable to induce sciatica, and when it is in the back of the neck, occipital neuralgia is a frequent consequence. Electric treatment of these non-traumatic cases is of course useless, while the process heals under relief from pressure with massage and medico-mechanical measures. Auscultation is even more instructive, he states, in the traumatic cases.

88. **Treatment of Parenchymatous Keratitis.**—Cohn reports 2 cases cured by instillation of 1 per cent. sodium cinnamate with 1 per cent. cocain in physiologic salt solution. Improvement was apparent in a few days.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MEDICAL FEES IN COUNTRY PRACTICE.*

W. O. BRIDGES, M.D.

OMAHA, NEB.

At no time in the history of this country has general prosperity among our people been on so high a plane. To whatever preponderating cause theorists may attribute this fact, it must be admitted by all that one of the chief of those advanced is the financial independence of the American farmer. To him we owe the origin of a large proportion of all wealth. From him we expect the purchase, utilization and consumption of products and manufactures applied in his supplemental sustenance and as a means toward the accomplishment of his work and the comforts of his home. Between him and the source of his purchased needs is that great army of so-called middlemen inhabiting the great cities, manufacturing centers and the country towns and villages, whose very life is largely, if not completely, dependent on the tiller of the soil.

When the American farmer is prosperous, prosperity is general. In time of drouth, the manufacturer, the merchant and the coupon cutter experience adversity. Cities destroyed completely by Nature's freaks and fires rise again in the night, grander, loftier and more attractive than ever. Destruction of the tillable soil by whatever cause means devastation, poverty and distress, possibly for all time. There is no prosperity so continuous, so substantial and so elevating to mankind as that whose foundation is laid by the man, who, profiting by his knowledge of natural laws, digs out of the ground that which goes to support his fellow-man. To this account more than any other may be laid the wonderful accomplishment of this republic in a trifle over one hundred years, occupying to-day probably the foremost position among the nations of the earth.

The prosperity of the farmer affects directly the middlemen in his nearby town. When the farmer has plenty to sell at good prices, the banker, preacher, storekeeper, druggist, carpenter, painter and saloonman are kept busy in his wake. The result is more work, better returns and a general advance in the material development of the town. These thoughts, with the knowledge which has come to me of the fees charged by physicians in country practice, have led to the query: Does the country doctor participate in the benefits which accrue to his fellow-townsmen, because of the material advancement of the farmer, in like degree? In other words, has his income from his practice kept pace with the times? Is he receiving the remuneration commensurate with the increased cost of his education, with the advance in the price of his necessities, the hard work and responsibilities of his calling?

PHYSICIANS' FEES.

In a somewhat extended association with the physicians of Nebraska and western Iowa, I have come to learn something of the details of their work, the trials of their life and their compensation for service. Two facts ascertained have impressed me, one, the uniformity of their fees, and the other the low prices charged. For instance, inquiries of men, practicing in Iowa, north, east, central and southern Nebraska, in towns of 1,500 or less, showed up a schedule about as follows: Day visit in town, $1.00; office consultation and prescription, 50 cents; visits in the country, mileage one way only, 50 cents, and in some instances (a minority) $1.00 in addition for the call; obstetric attendance, $10.00 in the country and a few reported mileage 50 cents in addition. Many make no additional charge for instrumental deliveries, and those who did made a fee of $5.00 in addition. An extra charge for night work of any kind was a rarity, and the fees were not affected by storm, deep mud or other influences occasioning delay and undue exposure.

Individual reports, particularly of obstetric experience, were interesting, and some of which indicated a disposition to charge less than the schedule. I will recite one in point: Dr. T. was called four miles from town to assist Dr. B., who had been with a primipara twelve hours. Forceps had been applied at the inferior strait without result after prolonged effort. After examination and consultation, Dr. B. gave an anesthetic, Dr. T. applied the forceps and in an hour later delivered the child with a considerable perineal tear, which was repaired. Two weeks later Dr. B. asked Dr. T. what his fee was. He replied: "Oh, $15.00." Dr. B. rejoined: "That seems pretty steep, as I can not send them a bill for more than $20.00 for both our services and I had to catheterize her for three days after delivery." Dr. T. replied: "Then, make it $10.00." The patient's family was in comfortable circumstances.

COMPARISON OF CHARGES IN VARIOUS PARTS OF THE COUNTRY.

Several weeks ago, desiring to ascertain how the fees charged in this section of the country compared with those elsewhere, I wrote a number of letters to physicians in small towns in various parts of the country and received answers from North Carolina, Texas, Wisconsin, Arkansas, North Dakota, California and Utah. In all except two, Wisconsin and North Carolina, town visits were charged at $2.00 or above (California $2.50); office consultations, $1.00 or above (California $1.50). Three physicians reported visits in the country at $1.00 mileage one way, without extra charge for visit, one the same with $2.00 extra for visit, and three 50 cents mileage and $1.00 extra for visit. Consultation fees were $10.00 in four reports, $5.00 to $10.00 in one and $5.00 in two. Obstetric attendance was reported at

---

* Read before the Nebraska State Medical Society, Lincoln, May 5, 1906.

$25.00 in one (California), $25.00 in town and $30.00 out, in one (Utah), $15.00 in one (North Dakota), $10.00 and mileage in one (Wisconsin), and $10.00 in three. Forceps delivery additional charged in one $25.00 (Texas), $10.00 to $25.00 in one (Utah), $10.00 to $15.00 in one (California), $15.00 in one (North Dakota) and $5.00 in three. For night visits three physicians reported double day charges, two one-half more and two no extra charge. While there is no complete uniformity in the answers to my queries, it is very evident that in all save two (Wisconsin and North Dakota) the fees charged for like services are much higher than they are here, and yet it must be assumed that Iowa and Nebraska are as prosperous to-day as any section of the country.

INCREASED FEES OF ADVANTAGE TO PATIENTS AS WELL AS TO PHYSICIANS.

Looking over the subject of physicians' fees in the past twenty-five years, one is impressed with the fact that the charges made by men in country practice have not advanced one cent, whereas the classes of people whom he serves have doubled, trebled and even quadrupled their incomes. Twenty-five years ago the outlay for the physician's medical education in time required and money expended was less than one-half the present cost and in consequence thereof the value of service which he gives to-day as compared with the former period can not even be measured in dollars and cents. The charge of 50 cents for an office prescription may be all the prescription is worth many times, for, if it is the prescription which the fee is made for, the patient is not getting more than his money's worth. Too often is this impression given to patients or too seldom is he led to understand that the prescription is only an end result of an examination which requires technical knowledge and experienced judgment. A 50-cent fee is too apt to mean a 50-cent service. This is no reflection on the doctor whatever, for human nature is the same everywhere, and so long as it is the custom for our services to be measured in money value the reverse in most instances will apply, the value in money determines the service. To state an opposite hypothesis may make this statement seem less critical. Suppose the fee charged for office consultation were arbitrarily fixed at $5.00, is there a single physician in this state who would be content simply to ask a few questions, look at the tongue, determine the absence of fever, by the hand contact, turn around and write a prescription? What applies to a 50-cent office fee applies also to a dollar visit in town, a mileage of 50 cents without visit fee in the country and a twenty-four to forty-eight hour obstetric fee of $10.00. The low-fee proposition has two principal bad results for the physician. By the undervaluation of his own service, his confidence in himself in time suffers, his work becomes superficial and he ceases to develop, and, failing to earn a competency during the active years of his professional life, he too frequently goes into his old age without the necessities of life or is dependent on relatives for support. On the other hand, fees proportionate to good service mean much to the doctor. The stimulus to be thorough and painstaking, to think and to study over his cases, to relieve him of the necessity of outside financial interests, means much for his professional advancement, for the increased revenue and his inclination lead him to seek the change and advantages offered by the postgraduate schools and by the hospitals of nearby cities. He also feels better able to afford the time and pleasure of the county, state and national societies more frequently.

There is no community which would not be greatly benefited by an increased income to all the members of the profession in their midst. Suppose, for example, that each physician in a town having six physicians should devote from three to six months every six years to postgraduate hospital work, what effect would this have on the value of his service and who else would profit by it? Does a physician ever go to a county, state or other medical society meeting without receiving some new suggestion or having awakened some new thought? If he goes to Chicago, New York, Philadelphia or Baltimore for a month in contact with other medical men, does he not return with renewed determination to get out of a rut and to stay out? If he can figure that his professional income will admit of his doing this, and that by so doing he will gain vantage ground, and by the very move still further increase his income, is he not standing in his own light not to do it? Farther than this, does not his duty to his patrons and his influence in the community require him to do it? And if so, should they not pay for it in fees which will permit of a little more than a comfortable living? When I have talked with some of my professional friends about this subject, the reply has been "The fees in our community have been fixed so long that our patrons would rebel at any increase, and, furthermore, there would be lack of uniformity in competing towns and we might sacrifice our business." To the first suggestion I would offer a protest. From what I have written above as to the character of the service, it is assumed that the farmer or the tradesman is willing to pay for what he buys. If he is made to see that what he buys is worth the money, he pays. That he is not averse to doing so can be demonstrated time and time again, when he is seen to pay railroad fare in addition to a good-sized consultation fee to some city doctor, who may be no better or perhaps not so good as his own physician.

The increase and prestige of men aiming somewhat at specialization in small towns is an indication that good fees may be asked and collected without hesitation. Recently I saw a patient with her physician four miles from a town of 400 in the central part of the state. In eliciting the history, it was ascertained that six months ago the previous physician's first introduction to the family had resulted in a diagnosis of a large ovarian tumor. He advised her removal to a city hospital for an operation. Following part of his advice, she went to the next town, where the tumor was removed by a local surgeon who charged and collected $300.00 and $20.00 a week for a room and nursing. Let any one tell me that farmers will not pay the price, when this same work could have been done in Omaha for $50.00 and in Lincoln for probably $75.00.

ORGANIZATION AND A FEE SCHEDULE.

The frequency with which farmers and people from small towns go to nearby cities for minor medical and surgical consultation, ignoring often the local physicians, is, to my mind, the surest indication that they want to pay more, for, as a disinterested spectator, I have often seen them go to men inferior in every way, except in the fee. A young physician recently located in a fine Nebraska town complained to me that the outlook was poor, for nearly all the best people there went to the city, twenty miles away, for their medical advice

I advised him of his great opportunity, for if he had the incentive to charge enough and an aim to earn his fee, with his qualifications, which I well knew, he could turn the tide in his own favor.

Would any reasonable man object to paying the doctor more for night than day work if asked? He has to pay the carpenter, the painter, the plumber who do overtime work at an increased rate, and why should he kick on the doctor? I have been surprised at the number of men who informed me that they did not discriminate between the fees for day and night work. A busy man at this rate burns the candle at both ends and quits at an earlier age without much to show for it. When one considers the number of unnecessary calls to which the physician is subject during his sleeping hours, he must feel that, with no difference in cost to the patron, it is a matter of slight concern whether he waits till night. An increase in the fee for this work would anticipate or postpone a sufficient number of calls to save the doctor much valuable time for his natural rest and keep him busier in the daytime. For the absolutely necessary work it would be a small man who would refuse double fee.

The question of custom and competition is advanced as a theory for low fees. How easy this can be corrected s exemplified by the statement of a physician from the southern part of the state to me only a few days ago. The subject of a fee schedule came up for discussion at a meeting of his county society, and an advance all along the line was agreed on. There were six towns in the county and between them a splendid large farming community. The new schedule was published in every newspaper in this county, duly signed by the members. He said there was some kicking for a while, but the new rates were soon accepted and had been in full force for some time. Organization, then, must be the solution of the question. The county and district societies should do as much for the doctor in this regard as they do in every other, and I am not so sure that a move in this direction by the state society for a minimum schedule which would be adopted by all its component parts would be in the right direction. It would do away with variations in schedules applicable to border towns and would be much more easily lived up to. I believe the competition element so far as fees are concerned in the selection of a physician is much overestimated. In time of drouth and depression, with poor crops and burdened farms, it might prevail, but certainly the drift at the present time of progress and prosperity is toward getting results, even if it does cost. Granting that nonmembers of societies or a few backsliders would keep up the old custom, this should not deter those who believe that a workman is worthy of his hire and by this very assumption attract those who believe with them. It was said of an old physician of my acquaintance that he had a large following, not because he knew more than any of his colleagues, for he really knew less than many of them, but because he charged large fees. If this kind of a bluff works, how much more effectual it must be if it is backed up by sincere effort, painstaking care, and a disposition to be worth the price.

My aim in bringing this subject up in this form is to unload a growing impression on my mind that the doctor in country practice in Nebraska is underpaid and that he himself is mostly to blame for it, that his schedule of fees has not advanced with the requirements of his education, of his needs and of his position, and that by means of a well-directed effort, individually and collectively, there is no reason why results should not be accomplished which would not only be to his advantage, but would react favorably on his constituency.

FURTHER OBSERVATIONS ON ROCKY MOUNTAIN SPOTTED FEVER AND DERMACENTOR OCCIDENTALIS.*

H. T. RICKETTS, M.D.
CHICAGO.

In view of the brief season during which Rocky Mountain spotted fever prevails, uninterrupted study of the disease is conditioned on the maintenance of the infection in experiment animals.

In a previous communication[1] my inability to preserve the disease by inoculation from guinea-pig to guinea-pig was referred to, and the hope was expressed that alternation of the infection between the monkey and the guinea-pig might result in the preservation of the virus.

This experiment has been entirely successful and Table 1 illustrates the life history of the virus since it was obtained from the patient, Bradley.

TABLE 1.

Number of animal.	Date.	Source, and Material Inoculated.
Monkey I	June 11	Patient, Bradley; defibrinated blood.
Monkey II	June 20	Monkey I; defibrinated blood.
Guinea-pig 12	June 27	Monkey II; fresh heart's blood.
Monkey IV	July 7	Guinea-pig 16; blood and organs.
Guinea-pig 16	July 14	Monkey IV; defibrinated blood.
Monkey V	July 22	Guinea-pig 16; blood and organs.
Guinea-pig 17	July 28	Monkey V; defibrinated blood.
Monkey VI	August 3	Guinea-pig 17; blood and spleen.
Guinea-pig 25	August 16	Monkey VI; blood and serum.
Monkey VIII	August 23	Guinea-pig 25; blood and organs.
Guinea-pig 36	August 30	Monkey VIII; spleen.
Monkey IX	September 6	Guinea-pig 36; blood and organs.

All infected animals have run identical courses of fever, which are typical in this respect, that an incubation period of from two to four days intervenes between the time of inoculation and the onset of the regular febrile course. Commonly a moderate rise in temperature follows immediately on the inoculation and persists for one or two days, then falls near to normal for one or two days more, when the customary course sets in. This initial or primary fever probably is caused by intoxication from the large amount of material which is frequently injected. When a smaller amount of blood or emulsion of tissue is used this initial fever has not appeared.

Several facts are relied on in concluding that the disease transferred by these inoculations is spotted fever rather than some other infection which may have crept in during repeated passage. In harmony with the experience which was met in making cultures from man, no growth is obtained from the blood of infected animals, provided the cultures are made at a time when agonal or postmortem invasion by common bacteria has not taken place. If plates are inoculated with the heart's blood at the instant of death, it is customary to obtain no visible growth on ordinary media, yet this same blood proves infectious for other animals. Again, the rather frequent development of a

[1] The Study of Rocky Mountain Spotted Fever (Tick Fever?) by Means of Animal Inoculations, THE JOURNAL A. M. A., July 7, 1906.

hemorrhagic eruption in the monkey or guinea-pig, a manifestation which is identical in appearance, if not in distribution, with that seen in man, speaks for spotted fever rather than some other infection. This eruption is much more constant in the monkey than in the guinea-pig. In both animals it begins on the scrotum and foreskin. In the guinea-pig it may be found on no other part of the body, although it can be seen as a more or less generalized eruption occasionally. The external genitals of the female guinea-pig commonly become swollen and congested; recently, however, extensive hemorrhages have occurred in the skin of the labia in a number of females. But one female monkey has been used, and in her no cutaneous hemorrhages were discovered. It will be readily understood that the detection of a pink roseolar eruption in either the monkey or the guinea-pig is difficult. In the guinea-pig it can be recognized with certainty only in white-skinned animals. In both animals the hemorrhagic eruption, when it appears, is a late manifestation and it would seem to be related in some way to the virulence and duration of the infection. The disease may be so virulent that the animal dies before the eruption would appear, or so mild that it does not occur. The appearance of the hemorrhages does not necessarily presage a fatal issue; two monkeys and several guinea-pigs which had extensive hemorrhages into the skin have recovered.

A third fact which stamps this experimental disease as spotted fever consists of the identity of the course of fever with that produced in the animals by direct inoculation with human blood.

The essential anatomic changes, enlarged spleen and lymph glands, congested kidneys, etc., are identical with those seen in the animals first inoculated, and correspond with the changes found in man.

There seems to be no particular difficulty involved in perpetuating the infection, except in the matter of expense. Duplicate inoculations should be made and the blood or organs used for inoculation may be taken at any time after the fever has reached its high point. To await the death of the animal before making the transfer is to risk the loss of the culture; the animal may recover.

THE DISTRIBUTION OF THE VIRUS IN THE BODY OF THE INFECTED ANIMAL.

In my first experiments the infectiousness of the blood, in spotted fever, was demonstrated. It would naturally by inferred that the various organs are infectious at least to the degree in which they contain blood. On this account one would reasonably expect the spleen to be infectious and this has proven true in a number of inoculations. The testicles have been used for inoculation a number of times. It was thought that the testicles might be a point of predilection for the virus, in view of the severe hemorrhages which often occur in close proximity to them, i. e., in the scrotum. They were shown to be infectious in several instances, yet their virulence was not so great as to indicate any special concentration of the virus at this point. The scrotal hemorrhages may have no relation to the amount of infection of the testicles.

The distribution of the virus among the organs of an infected monkey (VIII) was recently determined. The animal was exsanguinated from the carotid to deprive the organs of as much blood as possible. Each organ was then ground with sterile sand and suspended in physiologic salt solution. Identical weights of the different organs were not used, but approximately the same mass was employed in each case. A further attempt at uniformity was made by rendering the different emulsions of approximately the same density. Five cubic centimeters of each emulsion were injected intraperitoneally into guinea-pigs, which varied in weight from 350 to 550 grams. Table 2 shows the results.

TABLE 2.—The Infectiousness of Different Organs.

Number.	Material inoculated.	Result.
35	Mesenteric, inguinal and axillary lymph glands.	Death in 18 days.
36	Spleen.	Death in 7 days.
37	Bone marrow.	Death in 6 days.
38	Testicles.	Death in 15 days.
39	Liver.	Death in 8 days.
40	Kidney.	Death in 7½ days.
41	Medulla oblongata.	Recovered.
42	Cerebral cortex and adjacent white matter.	Death in 12½ days.

In the fatal cases cultures of the heart's blood were sterile except in the case of guinea-pig 37, in which a few colonies of a staphylococcus developed. The technical difficulties in preparing the bone marrow increased the opportunities for infection. It is thought very probable, however, that the animal died of spotted fever because of the duration of the course.

Those organs seemed to be the most infectious which contained, naturally, the most blood, i. e., the liver, spleen, and bone marrow (?). In these organs exsanguination still leaves rather large quantities of blood. The kidney, however, was fully as infectious as the organs which were much richer in blood. It is possible that the kidney becomes the repository of a larger mass of micro-organisms, by virtue of its excretory function. It is realized that this experiment does not give an exact measurement of the degree of infection of the different organs, and that the results, at the best, can be considered no more than approximate.

In another experiment an attempt was made to determine the minimum fatal dose of the blood of the infected monkey, the blood being taken six days after inoculation. The injections were intraperitoneal (Table 3).

TABLE 3.—Virulence of the Blood of the Infected Monkey

Guinea-pig.	C.c. of Blood.	Result.
30	0.5	Death in 14 days.
33	1.0	Death in 7½ days.
31	1.5	Death in 7½ days.
32	2.0	Death in 13½ days.
34	3.0	Death in 6½ days.

Plate cultures of the heart's blood were sterile in all cases. In this experiment the minimum fatal dose of the blood of the infected monkey on the sixth day of the disease was in the vicinity of 0.5 c.c. Guinea-pig 30, which received this dose, died on the fourteenth day, whereas, animals which live so long ordinarily recover. Guinea-pig 32, which received 2.0 c.c., showed unusual resistance. The guinea-pigs weighed about 350 grams each. Other experiments indicate that subcutaneous and intravascular inoculations have a similar degree of virulence.

ACTIVE IMMUNITY.

I have not learned of an authentic example of a second attack of spotted fever in man, hence it has seemed somewhat probable that one attack renders the body immune. This has been found to be true in a recent experiment on the monkey.

On June 20, 1906, Monkey II was inoculated with the blood of Monkey I, the latter having just died as the result of inoculation with the blood of the patient, Bradley. Monkey II ran a typical course of fever, showed a macular eruption of the perineal skin on the eighth day, and extensive hemorrhages of the scrotum.

perineum, back and extremities on the eleventh day. The temperature returned to normal on the twelfth or thirteenth day, hence the eruption became hemorrhagic as convalescence was about to begin. The animal regained its former health and activity.

Recently this animal was again inoculated with the blood and tissues of an infected guinea-pig (No. 36). The total mass of fluid injected was 8 c.c. With the exception of some indisposition on the following day, the injection produced no apparent effect. For a few days the temperature was slightly higher than before, but during this time and since the monkey has shown no indisposition and has been as active as before inoculation.

By way of control another monkey of the same size (No. IX) was inoculated with the same amount of material, the same quantity and by the same route. Between the third and fourth days the temperature began to rise, and until it was killed (7 days), it ranged between 105.1 and 106.3. The conjunctivæ became reddened, the animal shivered at frequent intervals and sat, inattentive and with head drooping, continuously. On the fifth day the supraorbital skin showed reddened patches, and on the sixth day a roseolar eruption was visible on the scrotum. The blood and tissues were used for further experiments.

From this experiment it is evident that one attack in the monkey confers an active immunity, and on the basis of reasonable analogies one may conclude that man probably acquires a similar immunity.

A similar acquired immunity has also been demonstrated in the guinea-pig. Its duration, beyond the period of two months for the monkey and three months for the guinea-pig, has not been determined.

THE LIFE HISTORY OF DERMACENTOR OCCIDENTALIS.

On account of the suspicion which attaches to *Dermacentor occidentalis* as the carrier, or a carrier of Rocky Mountain spotted fever, its life history is important. The following brief notes concerning this question are given by way of recording the changes which were observed under artificial conditions. No description of minute morphologic changes will be given at this time.

May 20, 1906, a fully developed female was placed in a cotton-stoppered test-tube.

June 21 (about), the tick began laying eggs, of which several hundred (estimated) were eventually deposited.

June 28 or 29 hatching began and continued for a week or ten days, resulting in six-legged larvæ of minute size.

July 13, the tube with its contents was placed in a tick-proof cage with a guinea-pig. The larvæ took hold readily for the most part, but did not feed continuously. They increased slightly in size. Eventually all remained attached to the skin for several successive days, grew to a length of 1 to 1¼ millimeters, and became swollen and of a uniform dark slate color. On August they began to drop from the guinea-pig, moved to a safe place, and went into a quiescent state, appearing as if dead.

August 5 they began to molt, throwing off a snow-white pellicle, and came out as eight-legged nymphs. After 7 to 10 days the molting of the brood was almost complete. When they first appeared they approximated the size of the well developed larvæ.

When again placed with a guinea-pig or monkey they seemed to feed intermittently for a time, but eventually attached themselves firmly and underwent a great increase in size, some reaching a length of about 3/16 of an inch. With the increase in size the color again changed to that of a uniform gray-brown or slate color. It required from 6 to 10 days for this development to take place after the ticks were placed with an animal. On August 30, practically all the ticks which remained alive had undergone this change.

As they reached the condition mentioned they were removed and placed in ventilated boxes where they went almost immediately into a second quiescent stage. In about 10 days molting again began, a white mantle being thrown off, and the mites emerged as adult ticks with the marking which one finds under natural conditions in the early months in Montana.

The experiment was carried on entirely at room temperature, and the various stages may not correspond in point of time with those taking place under natural conditions.

Under natural conditions, in the Bitter Root Valley, the adult ticks begin to disappear during the latter part of June. This probably means that the males, and those females which have not found a host, die, whereas the fully developed females deposit their eggs. Locally, knowledge of the further history of the tick was limited, or nil. It is certain, however, that during the warm summer days, the conditions are favorable for the hatching of the eggs, and for the development of the larvæ, provided a host is reached. Inasmuch as a crop of adult ticks is not observed in the fall, it is possible that the second molting stage, mentioned above, represents the hibernating stage of the mite. It is well known, locally, that the first few warm days of the spring bring out the ticks. These few warm days apparently would be sufficient to bring to completion the second molting stage. On the other hand, it must be admitted as possible that the second molting stage is completed in the late fall, and that hibernation begins at once with the animal fully developed, the first few warm days of spring being sufficient to arouse him.

Observations of a more complete nature will be made at a future date.

OSTEOPLASTIC RESECTION OF THE COSTAL ARCH IN ORDER TO REACH THE VAULT OF THE DIAPHRAGM.*

WILLY MEYER, M.D.
Professor of Surgery at the New York Post-Graduate Medical School and Hospital; Attending Surgeon to the German Hospital; Consulting Surgeon to the New York Skin and Cancer Hospital and to the New York Infirmary.
NEW YORK.

Of all the regions within the abdomen the vault of the diaphragm is the most difficult of access, principally owing to the unyielding character of the lower portion of the thorax.

Various methods have been devised to overcome the difficulty. In cases of subphrenic and intrahepatic abscess or cysts of the convexity of the liver, one or more ribs have been resected, the pleural sac traversed or pushed up and drainage in a straight direction arranged for.

For the same purpose Lannelongue did resection of the eighth to the eleventh costal cartilages or of the respective ribs—a rather extensive additional operation.

Micheli[1] worked out on the cadaver an operation similar to Schede's thoracoplasty. Of course, he avoids injury to the pleura and includes in the flap, diaphragm and parietal peritoneum. It seems that the operation was never done on the living subject.

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[1] Tenth Italian Congress of Surgeons, 1895.

While attempting to excise a carcinoma of the cardia and lowest portion of the esophagus, von Mikulicz once tried a plan very much like the one just described.[2] In a second case he made a median incision above the umbilicus, an additional transverse one at right angles with it and three further incisions, exposing the seventh, eighth and ninth ribs near their costo-cartilaginous junction, where the cartilages were divided. Then the flap plus costal arch could be pulled to the left and the cardia reached. In both instances the patient succumbed to the effects of the serious operation on the stomach.

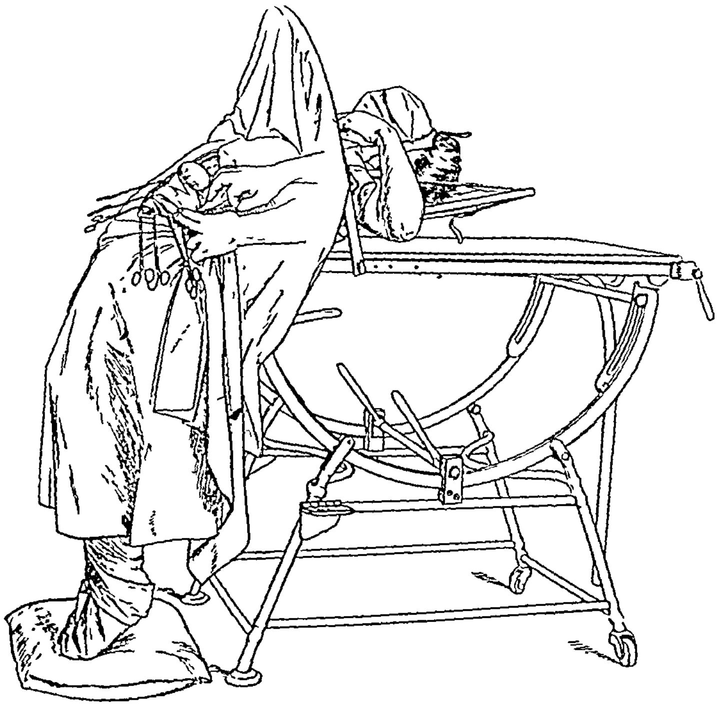

Fig. 1.—Kelling's position for the upper part of the abdomen.

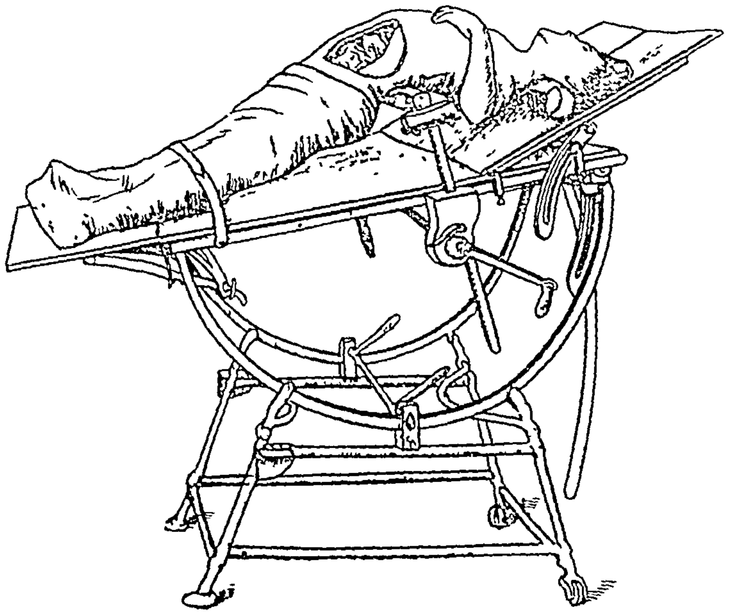

Fig. 2.—Kelling's later modification of the posture shown in Fig 1

In 1901 G. Kelling[3] recommended the posture which is best explained by Figure 1 taken from his article. It shows a Trendelenburg posture, as it were, for the upper part of the abdomen, "Beckenhängelage" in contradistinction to Trendelenburg's "Beckenhochlagerung." The posture seems cumbersome and makes the maintenance of perfect asepsis difficult. Later, Kelling[4] suggested in its place the posture shown by Figure 2.

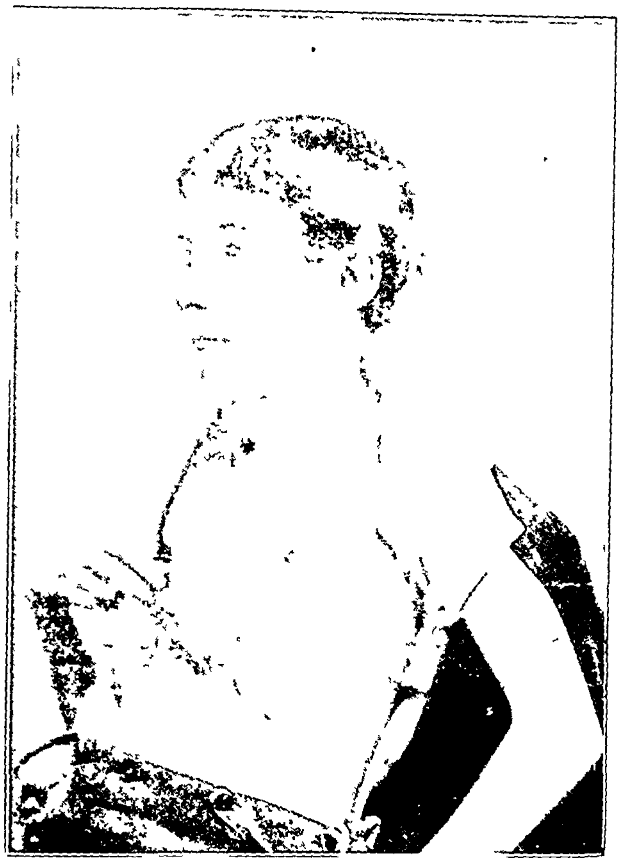

Fig. 3.—Osteoplastic resection of the costal arch in the presence of a gastric fistula by means of a U-shaped incision for an impermeable cicatricial stricture of the esophagus.

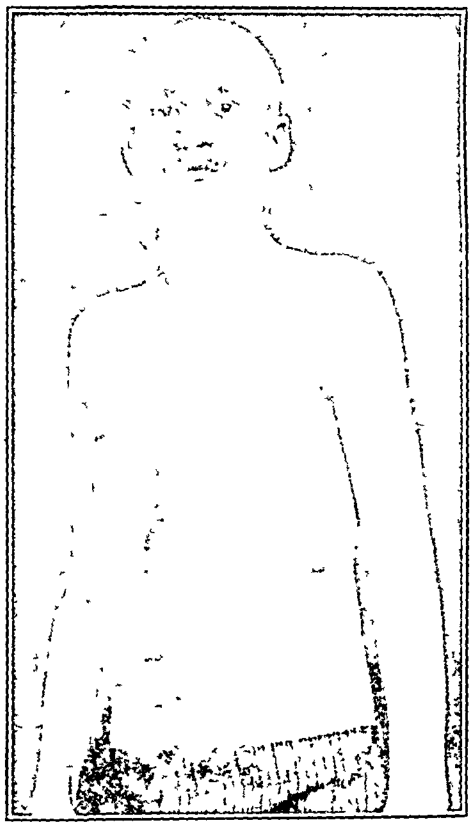

Fig. 4.—View of patient, four weeks after splenectomy for sarcoma

I doubt that this posture will make it possible to operate conveniently near the top of the diaphragm in difficult cases.

---

[3] Centbl. f. Chir., 1901, No. 42, p. 1025.

[4] Centbl. f. Chir., 1904, No. 4, p 89.

Two years later, G. Marwedel,[5] unaware of von Mikulicz's previous attempts in a similar direction, described a simplified operation, an osteoplastic resection of the lower anterior portion of the thorax which he had thoroughly worked out on the cadaver and once successfully carried out in the living. The operation is less complicated than von Mikulicz's procedure. Asthoewer,[6] a few months later, stated that he also had done two somewhat similar operations several years before Marwedel.

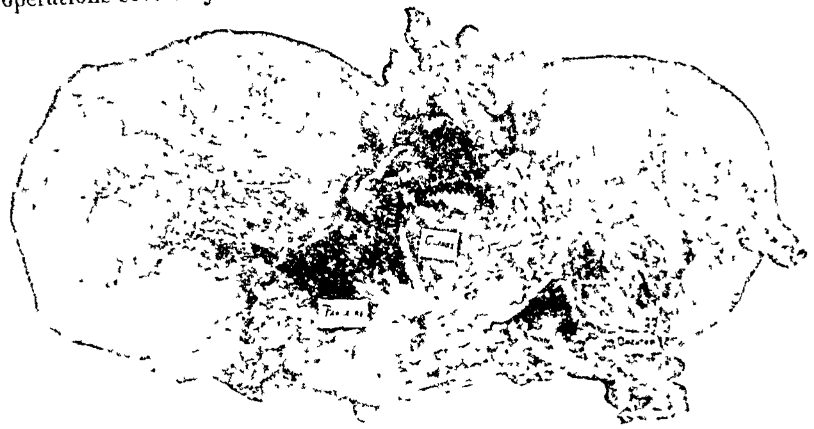

Fig 5.—Multiple sarcoma of spleen, secondary to retroperitoneal sarcomatous glands, the spleen being the only intraperitoneal organ showing metastatic growths. The distal half of the pancreas is attached to the tumor.

Within the last two years I have had occasion twice to employ osteoplastic resection of the costal arch. It enabled me conveniently to do the work required, which otherwise would have been impossible. The various steps and important points of the operation can be brought out best, I think, by briefly relating the histories of the two cases:

Case 1.—This case has already been fully described.[7]

Summary of History.—A boy, 14 years of age, had an absolutely impermeable cicatricial stricture of the esophagus (caustic lye). For eight years he had been fed entirely through a gastric fistula. All attempts to enter the stomach from above as well as under direct inspection with the urethral speculum introduced through an esophageal lip fistula in the neck having failed, an osteoplastic flap was raised by a U-shaped incision, the water-tight gastric fistula being carefully preserved (Fig. 3). A part of the anterior wall of the stomach, well above the fistula, was thus reached, horizontally incised and the passage upward searched for from below.

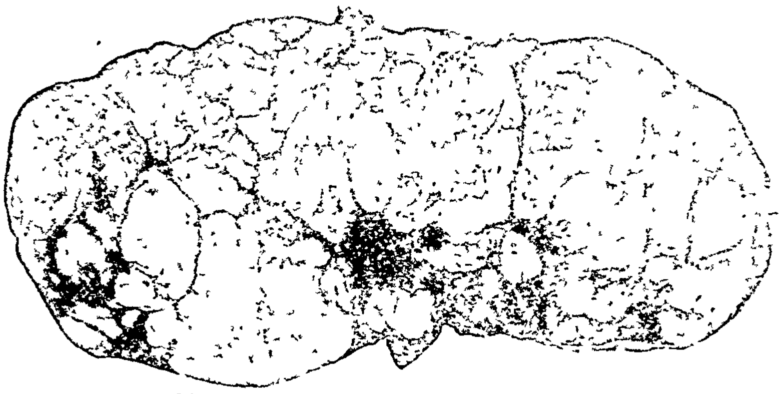

Fig 6.—Same specimen divided longitudinally.

To my great disappointment this attempt, too, proved unsuccessful. The esophagus was evidently entirely obliterated for some distance. The stomach incision was, therefore, closed again by means of a double row of Lembert silk sutures; the osteoplastic flap was fitted back in its place and the skin sutured; there was no drainage. The boy made a good recovery. I saw him a few weeks ago. He still nourishes himself through the tube (in all now for ten years) and has gained in weight.

Two ways are still open to help this patient: 1. To raise again the osteoplastic flap, this time opening the stomach by a perpendicular incision just below the cardia, which, as I had seen at the time of the first operation, could be entirely brought into view and pulled down from the foramen esophageum for fully an inch and a half; or, better, 2. To attempt esophagogastrostomy in Sauerbruch's chamber under negative pressure,[8] or in Brauer's new apparatus with the bronchial tree placed under increased pressure.[9] For the present the boy's mother is opposed to further operation.

Case 2.—Patient, a male, 29 years of age, came under my care in December, 1905.

He had entered the medical division of the German Hospital on account of a rapidly enlarging spleen and great weakness. The spleen was found to reach the umbilicus; its surface was nodular; there was some fluid in the abdomen. Diagnosis of malignant tumor (sarcoma) of the spleen was made and the patient transferred to the surgical division.

Operation.—On opening the abdomen, December 18, a large amount of sero-sanguinolent fluid escaped; the adherent omentum having been loosened and lifted out of the abdomen, the nodular spleen came into view. It was attached to many of the neighboring organs and particularly tightly fastened in the vault of the diaphragm. There was no metastatic growths in the liver or elsewhere. Radical operation was clearly indicated, chiefly in view of the patient's youth. Splenectomy was decided on. A transverse incision to the tip of the eleventh rib was added (Fig. 4). While this rendered access somewhat easier, it was still impossible to reach the upper pole of the spleen, although the lumbar spine had been well raised and the legs considerably lowered, while one assistant pulled the costal arch to the left with two hands, the other making traction on the enlarged spleen downward as far as possible.

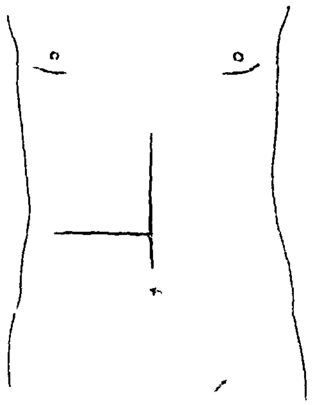

Fig. 7.—Right-angled incision.

It was evident that I should either have to give up or try some other way. The only chance of success seemed to lie in getting the costal arch out of the way. I therefore entered the space between the lower surface of the belly of the left rectus muscle and the peritoneum with posterior sheath of the rectus muscle, to which, further outward, the transversalis muscle is attached. From here I bluntly made my way upward to the border of the costal cartilages, which were quickly brought into view (Fig. 13).

This part of the work is very simple, for the reason that the rectus and external oblique muscles have their origin further up on the thorax and are attached to the latter in the portion concerned by very loose connective tissue only.

Then the seventh cartilage, representing the union of three,

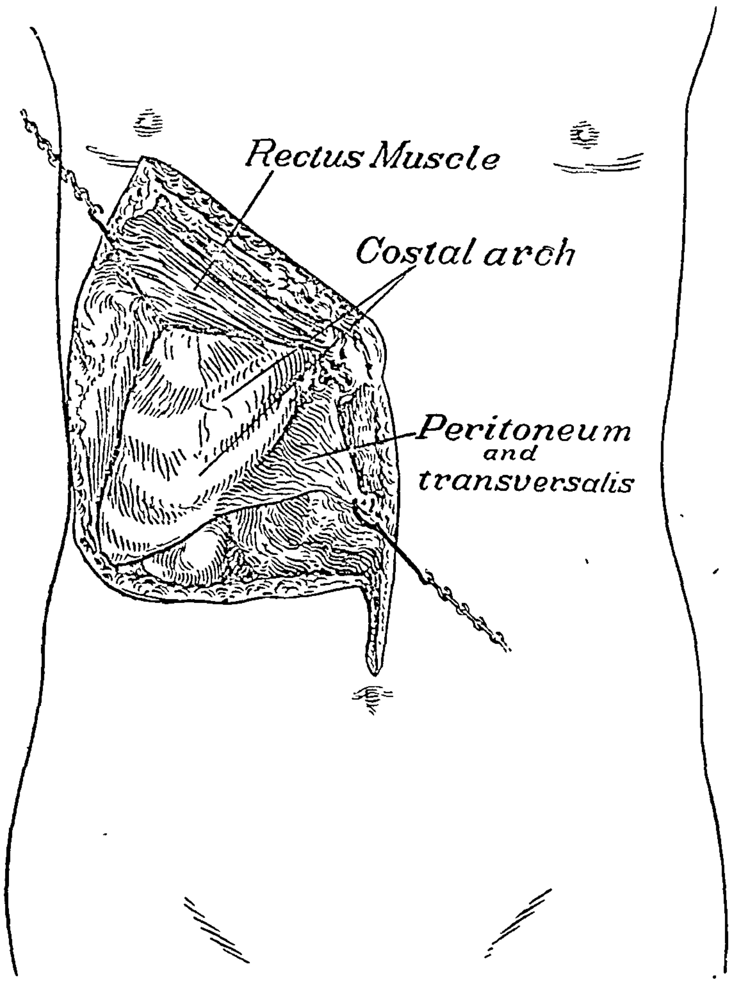

Fig. 8.—Right-angled incision. Skin-muscle-flap turned back, peritoneum and transversalis muscle remaining attached to costal arch, the latter exposed.

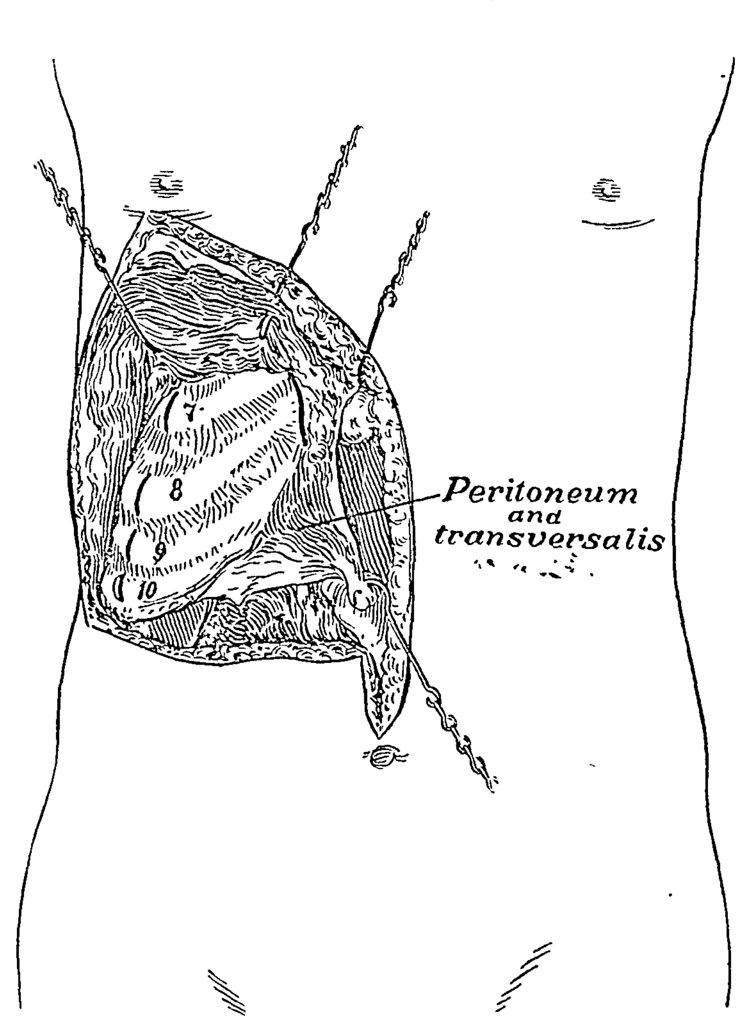

Fig. 9.—Right-angled incision. Seventh, eighth, ninth and tenth cartilages divided close to their juncture with the ribs; seventh cartilage, next to the sternum, also divided.

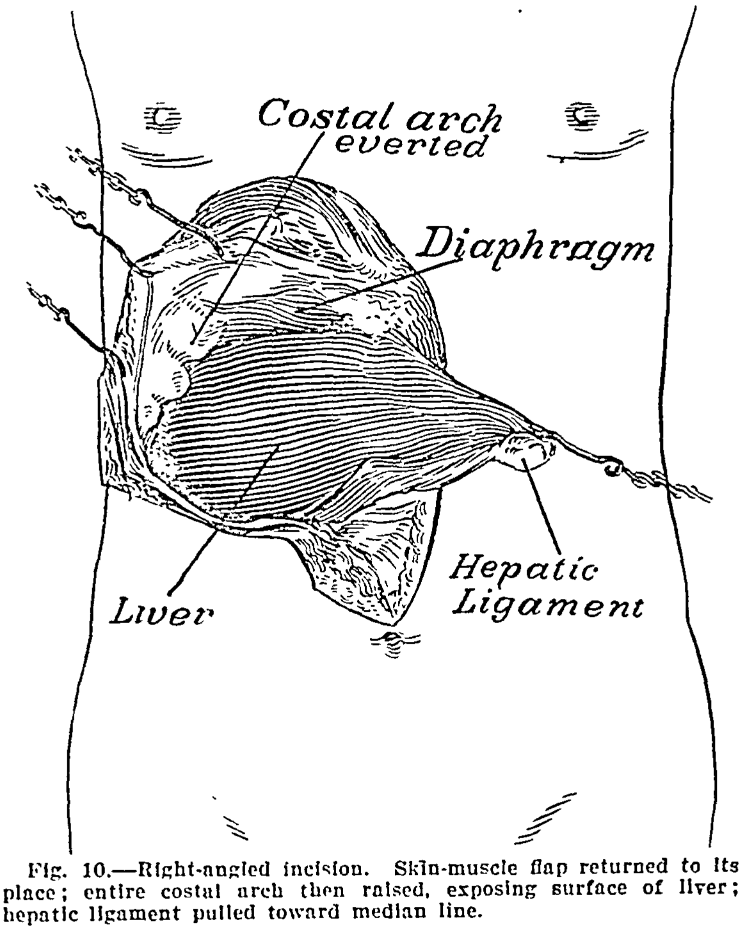

Fig. 10.—Right-angled incision. Skin-muscle flap returned to its place; entire costal arch then raised, exposing surface of liver; hepatic ligament pulled toward median line.

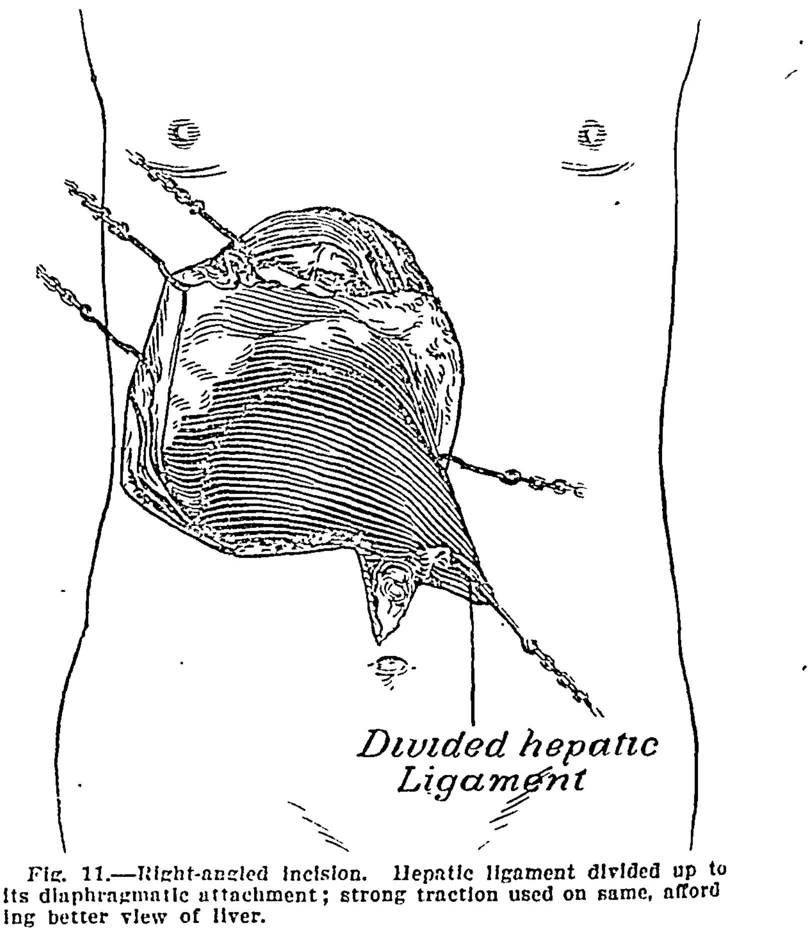

Fig. 11.—Right-angled incision. Hepatic ligament divided up to its diaphragmatic attachment; strong traction used on same, affording better view of liver.

was divided with the knife close to its sternal attachment, care being taken not to allow the knife to slip; and the seventh, eighth, ninth and tenth cartilages likewise, just in front of their union with the ribs (Fig. 14). Now the skin-muscle-bone flap is replaced in its normal position; two sharp retractors are hooked into the peritoneum and the costal arch is raised,[10] while the second assistant takes hold of the spleen, pulling it gently but firmly downward and inward.

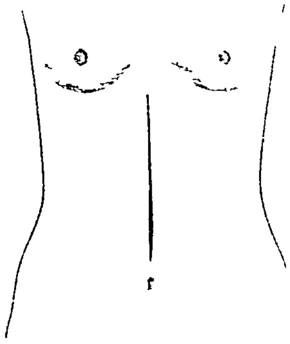

Fig. 12.—Straight, median incision.

It truly was fascinating to observe how readily the upper pole of the spleen with the ligamentum phrenico-lienale came into view and how the latter—in this case a short, broad, thick band —could be ligated in sections and then divided between two ligatures. The most delicate work in splenectomy, the division of the diaphragmatic attachment, could thus be carried out neatly and safely and in full view of the operator. Thereupon the spleen could be turned around its transverse axis, the upper pole made to emerge from the abdominal cavity and the whole organ gently pulled up by the first assistant, its pedicle thus being well stretched. It proved to be firmly adherent to the tail of the pancreas. From the latter a mass continued upward with the vena cava. I had to push off the latter, place a double chromicized catgut ligature around the body of the pancreas, divide it between the ligatures with Paquelin's cautery and tie off the greater portion of the adherent omentum At the splenic hilus only the large vein came into view. It, too, was divided between two ligatures, thus completing the operation, which had been done throughout in an absolutely bloodless manner. (Figure 5 nicely reproduces the interesting specimen.) Thereon a Mikulicz's tampon was placed in the diaphragmatic vault, the osteoplastic flap returned and pressed in position and the T-shaped abdominal wound carefully sutured. The abdomen was well strapped with zinc adhesive plaster and a snugly fitting binder tied around it. After two stormy days, when intravenous and subcutaneous saline infusions had to be freely used, the patient made a satisfactory recovery. He was up and about at the end of the fourth week (Fig. 14).

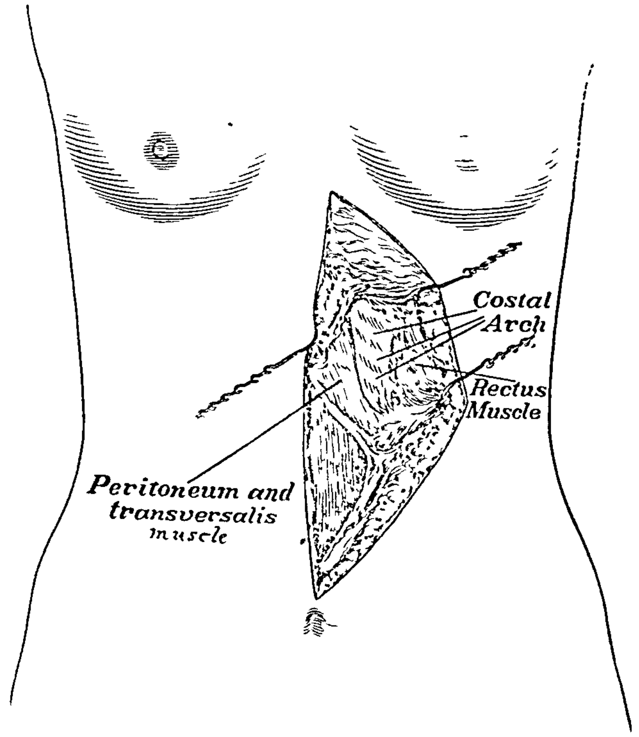

Fig. 13.—Straight median incision. Rectus muscle pulled outward and upward, peritoneum and transversalis muscle inward; costal arch exposed.

The spleen, twelve inches long and seven inches wide, weighing five pounds, when divided showed the typical picture of a secondary (metastatic) multiple tumor (Fig. 16), which, on microscopic examination, proved to be a small round-celled sarcoma.

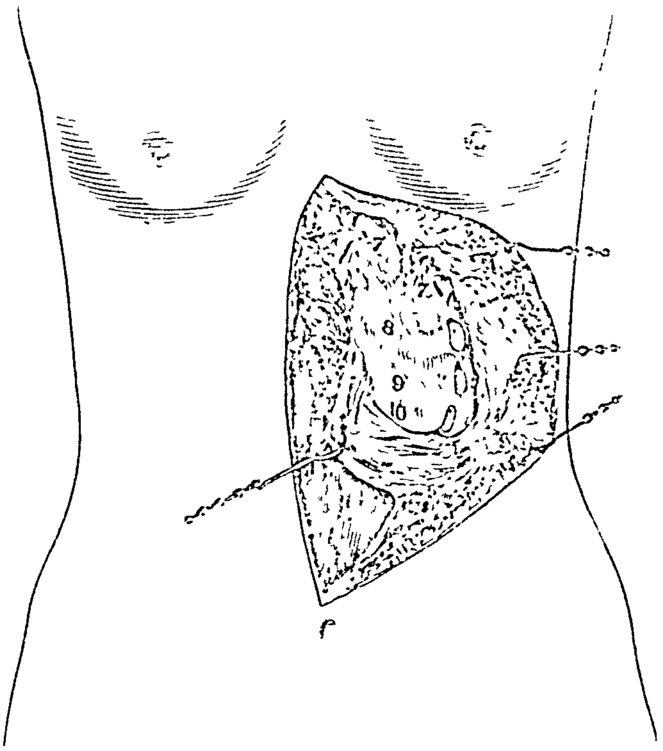

Fig. 14—Straight median incision. Cartilages divided. In this specimen the cartilage of the eighth rib is not united with that of the seventh near sternum.

Of course, with such a microscopic diagnosis there was no hope of the patient's permanent recovery. We tried the *x*-rays, but without avail. He died suddenly, Feb. 26, 1906, ten weeks after operation, as a result of internal metastases. Autopsy showed the costal cartilages to have healed in place without any deformity and with good ligamentous union.

I believe that the primary tumor in this case had developed in the retroperitoneal glands which gradually approached the hilus of the spleen, the growth then perforating into the splenic artery and producing the multiple metastases found. This, at least, is the way I would venture to explain this peculiar dissemination of the disease in only one of the large intra-abdominal organs, and I do so on the basis of an observation I made a few years ago in a patient afflicted with carcinoma of the posterior wall of the stomach. Here the tumor had crept along on the outside of the gastric wall toward the right until it reached the portal vein, which it perforated. Then the blood current continuously took along and carried into the liver carcinomatous particles which produced intrahepatic (localized) metastases in an amazingly short time. The first embolic attack was marked by a chill and acute abdominal symptoms, simulating an abscess of the liver. Exploratory incision and postmortem, seven weeks later, explained this rare pathologic picture.

---

[10] Often the assistant's hands will be found more useful than retractors, as will also be seen in this case later on.

Both cases related above proved the great help we may expect from this osteoplastic raising of the lower part of the thorax, when it becomes necessary to reach ordinarily inaccessible organs within the phrenic convexity. It is natural that in cases of need the ribs may be divided in place of their cartilages, further outward, including also the sixth and fifth ribs. It further is evident that the flap may be shaped according to indication as in Case 1 (Fig. 3). On the right side the surface of the liver can be better reached by pulling on the suspensory ligament (Fig. 10) or by dividing the latter up to its attachment to the diaphragm and then using it for strong downward traction (Fig. 11).

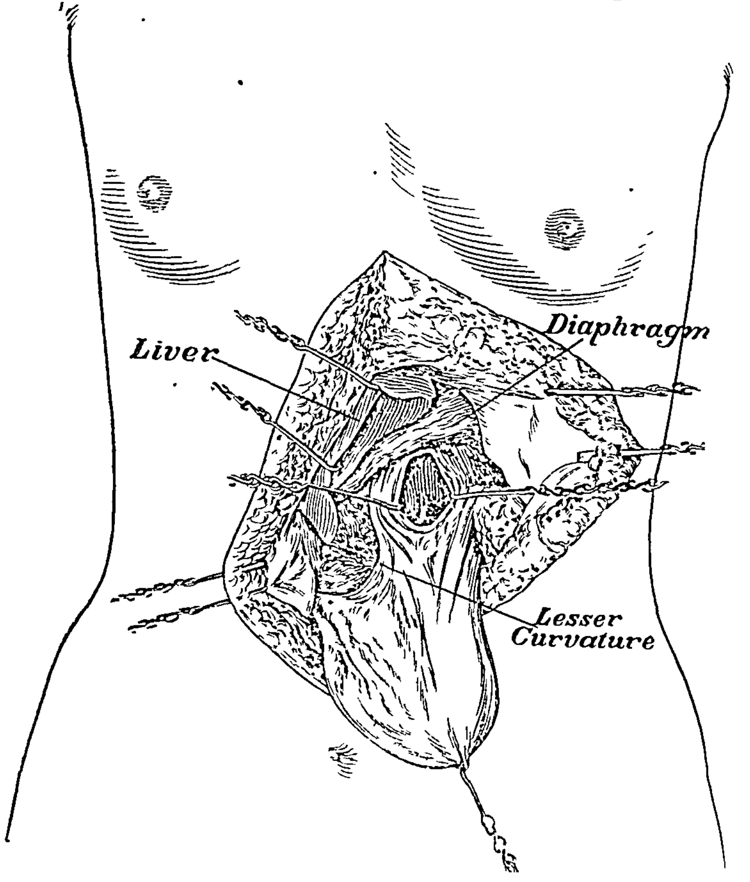

Fig. 15.—Straight median incision. Lumbar region of cadaver raised; skin-muscle-bone flap pulled upward and outward, exposing a large area of the stomach; the cardia incised and cut edges held apart by hooks.

Through the courtesy of Drs. John Rogers and Irving S. Haynes, of Cornell University, I have been able to make some dissections on the cadaver in order to test this operation in combination with the various abdominal incisions that come into consideration: median, oblique and ⊢. The illustrations, representing pen-and-ink drawings made from photographs of the dissections (through the laboratory of Dr. Fred E. Sondern), speak for themselves (Figs. 7 to 17).

From my experiments on the cadaver I have concluded that the usual median (or rectus) incision can well be combined with osteoplastic resection of the costal arch; but, of course, the space gained in connection with this incision is not as satisfactory as when the oblique or ⊢ incision is used. It seems to me that in cases of resection of the stomach, in which the cardiac portion and lesser curvature can not well be pulled downward, but exposure of same is imperative, the additional room gained by dividing the cartilages will make radical work practicable. On the other hand, operations on the spleen or liver, if started by means of a median incision, will require an additional transverse incision. If a careful plan can be laid out beforehand, and it is feasible to employ the oblique incision, this will be found to afford excellent access, after lifting the lower part of the thorax. The resulting wound is not so convenient for closure. Through-and-through sutures are advisable.

Cases in which this osteoplastic operation will prove especially useful are those of injury to liver and spleen (stab- and bullet-wounds, as well as lacerations, due to a blunt force), also injuries and diseases of the diaphragm (hernia) and of the cardiac portion of the stomach. Inflammatory troubles (liver abscess and subphrenic abscess) will be attacked to better advantage, I believe, through or just beneath the complementary space of the pleural cavity after resection of one or more ribs.

As far as I have been able to glean from the literature, osteoplastic resection of the costal arch has as yet received but little attention. It surely means a valuable addition to our operative resources. It renders possible much greater accuracy of work in a field hitherto more or less inaccessible.

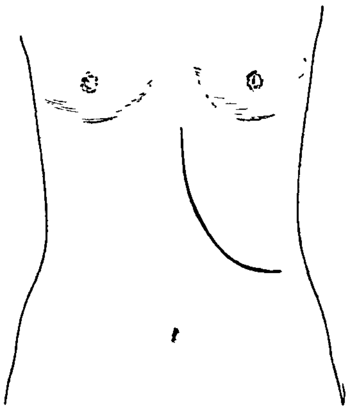

Fig. 16.—Oblique incision from xyphoid process to tip of tenth rib.

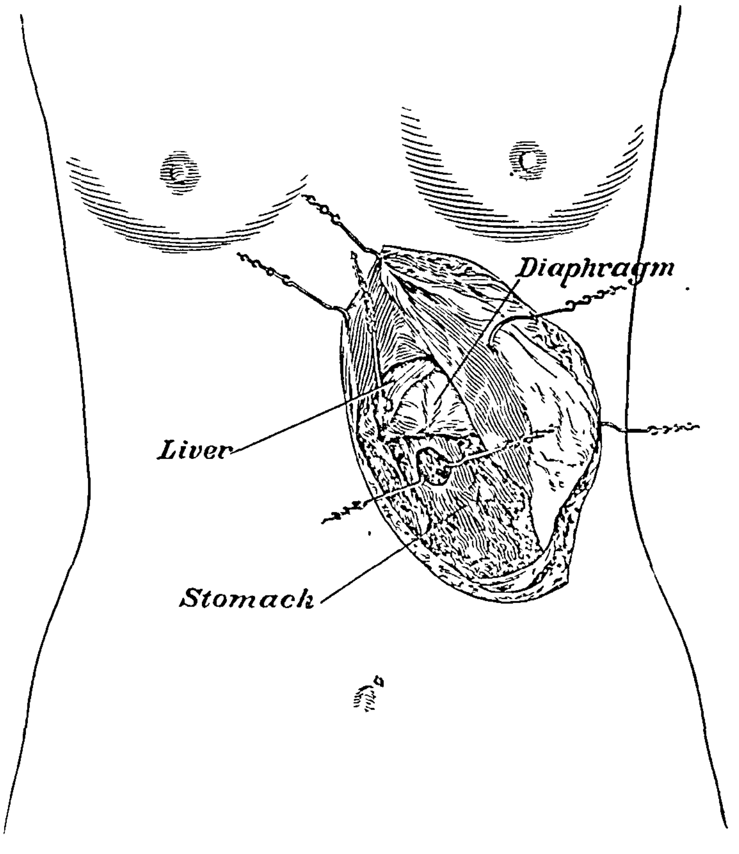

Fig. 17.—Oblique incision. After division of cartilages, as before, osteoplastic flap is raised, exposing vault of diaphragm and cardia. xyphoid process to tip of tenth

DISCUSSION.

Dr. D. N. Eisendrath, Chicago, asked why Dr. Meyer's operation would not be a practical one in the treatment of subphrenic abscesses following appendicitis, those that are situated between the diaphragm and the upper surface of the liver. These abscesses are comparatively common and the only way they can be dealt with at the present time is to go in below the costal arch, following up along the upper surface of the liver, or to go in transpleurally, then there is danger of empyema.

Dr. J. R. Eastman, Indianapolis, believed that Dr. Meyer's method of osteoplastic resection of the cartilages will have an important place in the treatment of gunshot wounds of the upper abdomen, especially those implicating the upper surface and the posterior border of the liver. He cited a case in point. A ball of large caliber passed in at the eighth rib, passing through the pleura, lung, diaphragm and upper border of the liver, causing great laceration and serious hemorrhage at the posterior upper margin of the liver. Cutting through the lowest ribs, he managed to plug in an unsatisfactory way the wounded liver. The patient died. Dr. Eastman thought that if Dr. Meyer's method could have been employed the result might have been different.

Dr. Willy Meyer, New York, stated that subdiaphragmatic abscesses are reached best by the transpleural route or, if possible, just beneath the lower end of the pleura by pushing the latter up bluntly. However, if continuous suture is made on either side of the pleural incision before opening the diaphragm, it is possible to avoid the appearance of a pneumothorax or empyema. Regarding the improved accessibility of shot wounds of the liver, etc., it stands to reason, he said, that by doing this osteoplastic operation we can reach the convexity of the liver equally as well as we can reach the spleen and cardia on the opposite side.

THE DIAGNOSIS AND TREATMENT OF TUBERCULOSIS OF THE KIDNEY.*

ARTHUR DEAN BEVAN, M.D.
CHICAGO.

Although Ammor as early as 1833 pointed out clearly the essential clinical points of kidney tuberculosis, it has only been within the last ten years that the diagnosis and treatment have been placed on a sound working basis, and even to-day the frequency and importance of the lesion is not generally understood by medical men. To those of us who have been medical students for twenty-five years or more the evolution of this subject during that period furnishes some interesting reading.

Ebstein[1] reviewed the subject and described the process as a cheesy inflammation involving the kidneys and renal pelvis and ureters, as one difficult to diagnose except in the presence of some evident tuberculous lesion; having a bad prognosis; as a condition in which the patient seldom lived more than a year. Ebstein states that all treatment is apparently hopeless. No suggestion of surgical interference is made.

In 1884 Henry Morris described the condition under the two titles of tuberculous disease and scrofulous disease of the kidney. He gives a very good clinical picture and says the treatment consists in alleviating pain and improving the general health. Further, he says that in tuberculous disease, in which the affection of the kidney is but a local manifestation of a constitutional disorder, nephrectomy would be useless, even if the other kidney were sound. When the scrofulous disease is limited to one kidney, nephrectomy promises much as a means of prolonging life by freeing the individual from a fatal malady.

In 1885 Samuel W. Gross read a paper on the subject of *nephrectomy before the American Surgical Association*, in which he collected twenty cases from the literature in which nephrectomy had been made for so-called strumous kidney, with twelve recoveries and eight deaths. An analysis of these cases showed that but the one kidney was involved in 65 per cent. of the cases, and that in cases in which a previous nephrotomy had been done no permanent relief was afforded by it, and he advises on this account an immediate nephrectomy when possible. Very few of these cases were done in America.

In 1885, in the German Congress of Surgeons, H. Fisher stated that all extensive operative procedures, "especially nephrectomy," for tuberculosis of the kidney should be condemned. In the same year von Volkmann said that he doubted whether operative treatment of tuberculosis of the kidney and kidney pelvis had any real value.

In 1891 Madelung collected sixty cases of nephrectomy for tuberculosis from the literature and reported three *of his own cases*. Eleven died from the operation and five within five months. He concludes that the operation is indicated when we can prove that the process is limited to one kidney.

In 1892 Tuffier reported twenty-five nephrectomies for renal tuberculosis, with 47.8 mortality and with but two definite cures, and fifty-seven nephrectomies, eleven abdominal, with 36.3 mortality, and forty-six lumbar, with 28.2 per cent. mortality.

In 1896 Dr. Willy Meyer,[2] New York, read a paper before the Medical Society of the State of New York, in which he emphasized the important facts that tuberculosis of the kidney is almost always at first unilateral and that it descends from the kidney to the bladder. He brings out clearly the value of the cystoscopic examination in making a diagnosis and calls attention to the peculiar appearance of the mouth of the ureter of the affected kidney. The mouth of the ureter, being indurated, presents a number of circumscribed, clearly defined, inflamed areas of mucous membrane between it and the trigonum. He says: "I could not compare this picture better than to liken it to the footprints in the freshly fallen snow."

He says too much stress can not be laid on the necessity of establishing a strictly defined diagnosis as soon as possible and of carrying out that treatment, which alone is the logical sequence of the same, to-wit: an early extirpation of the primarily diseased kidney.

In a monograph on tuberculosis of the genitourinary organs, published in 1897, Senn advocates nephrectomy, except in the cases in which the surgeon can satisfy himself that the opposite organ is present and in a healthy condition, and he dwells on the great difficulty of obtaining this evidence. Owing to the uncertainty of diagnosis during the early stages of renal tuberculosis and the existence of incurable complications in more than 50 per cent. of all cases, he says that the surgical treatment has not yielded as many permanent results as was anticipated during the early history of nephrectomy for this affection. He pleads for earlier diagnosis and earlier surgical interference.

In 1900 Ramsay, of Baltimore, published in the *Annals of Surgery* an article on renal tuberculosis, in which he collected 304 cases in which some form of operative treatment had been followed. Of these, fifty-five were nephrectomies with fifteen deaths within a month and but four cures. Of 191 primary nephrectomies there were 106 complete cures, thirty-one were improved, thirty-seven died within a month and seventeen later than one month after operation.

---

[2] Meyer, Willy: "The Early Diagnosis of Tuberculosis of the Kidney," Medical News, March 7, 1896.

In 1901 Israel published his great monograph, reporting the kidney cases handled in his surgical clinic. Among these were thirty-one cases of tuberculosis. He made a nephrectomy in twenty-eight, a nephrotomy in two and a resection in one.

In 1903 Kuemmell and Rumpel reported the extensive kidney work of the Allgemeinen Krankenhaus in Hamburg. Among these are thirty-four cases of tuberculosis and among these thirty nephrectomies with twenty-seven cures and three deaths, and four nephrotomies, two deaths and two improved.

In 1904 Kroenlein reported on kidney tuberculosis and the results of operative treatment from his own clinic. He operated on thirty-nine cases of kidney tuberculosis, three times opened perinephritic abscesses, twice did nephrotomy and thirty-four times nephrectomy. He regards nephrectomy for tuberculosis, when limited to one kidney, as one of the most successful operations in surgery.

It is the intention to show in this brief paper that the views on the subject of kidney tuberculosis have changed greatly within the last twenty years, that to-day tuberculosis of the kidney is known to be a common disease, that it is almost always the result of infection through the circulation, that in 90 per cent. or more of the cases it is primary in a single kidney, that it is the duty of the general practitioner to diagnose early these cases and that it is the duty of the surgeon to operate on them early, because an early operation holds out a good prospect of cure. There was a time when the handling of a case of kidney tuberculosis was purely medical. In the enthusiasm of the early successes, surgeons said, tuberculosis of the kidney is a surgical disease and attempted to place the responsibility entirely on the surgeon.

We can say to-day that the responsibility of the successful handling of renal tuberculosis is divided equally between the physician and the surgeon. The physician must learn to recognize these cases early, at the time when the process is still limited, as it usually is, to one kidney; the surgeon must learn that the radical removal of the kidney involved holds out practically the only hope and, fortunately, a very large hope for the patient.

GENITOURINARY TUBERCULOSIS.

Before taking up the special subject of renal tuberculosis it will be necessary to say a word on the subject of genitourinary tuberculosis in general.

Within the last ten years the subject of tuberculosis of the genitourinary tract has been most carefully studied and new clinical and pathologic evidence obtained and carefully analyzed. This has been made possible by additions and refinement in our means of diagnosis. Of these, the careful examination of the catheterized centrifugated urine for tubercle bacilli, pus, blood, etc., the obtaining of the urines from the two kidneys separately by means of various segregators and especially by catheterizing the ureters, more frequent and intelligent employment of the cystoscope and the use of the x-ray and cryoscopic examinations of the blood and the urine and the more systematic histologic examination of tissue removed at operations, must be mentioned as the most important. Tuberculosis of the genitourinary tract, with but few exceptions, begins at one of four points: the kidney, the prostate, the epididymis and the tubes. It is difficult to state which is the most common focus of infection, although evidence has seemed to favor the conclusion that the kidney and the tubes and the epididymis are the common foci and are primary in about an equal number of cases, the prostate occupying the fourth place with a smaller but very considerable percentage of cases.

The kidney, tubes, prostate and the epididymis are as a rule, primary only in the sense that in the individual affected they are the overshadowing and important focus of the disease. They are strictly secondary to a small, unimportant focus in the lymphatic glands bones or lungs, the infection occurring through the blood. Infection of the genitourinary tract through the urethra and vagina, as in gonorrhea, is to be admitted as a possibility, but must, as a clinical fact, be exceedingly rare. Probably the most important practical result that has been obtained from these more recen studies has been the knowledge that primary kidney tuberculosis is exceedingly common, and in probably 9 per cent. or more of the cases is for a time limited t first attacked. The work of Kuemmel Kroenlein, Israel, Si mon, the Mayos and myself h confirmed this fact. This knowledge has changed materially our views in regard to the treatment and nosis of these cases.

When the process is still limited to the kidney first involved, an early nephrectomy gives an excellent prognosis, both as to immediate and permanent results. On the other hand, the lesser operations, which have been so much employed, resection of the kidney and especially nephrotomy, are to be generally discarded. In the light of our present knowledge, resection in kidney tuberculosis has no place and nephrotomy is to be resorted to only as a palliative operation or to relieve urgent symptoms, such as sepsis and pain when the local condition is complicated, as, for instance, with a perinephritic involvement, or when the bad general condition of the patient makes the more radical operation unwarranted at the time. But even in these cases secondary nephrectomy is usually required in order to bring about a cure.

Tuberculosis of the bladder is seldom primary and is secondary to kidney tuberculosis, tuberculosis of the prostate or an extending tuberculosis from the epididymis. The treatment of this condition is still one of the unsolved problems of surgery and is to-day as unsatisfactory as it has ever been, with the exception of the cases of limited involvement of the mucosa, secondary, for example, to a primary focus in the kidney. In these cases it is not infrequently found that after the removal of the primary focus the limited lesion of the bladder undergoes a spontaneous cure. Ascending tuberculosis from bladder to kidney is probably rare.

Tuberculosis of the prostate was formerly believed either not to occur at all or to be exceedingly rare. Our recent studies have shown that primary tuberculosis of the prostate is by no means uncommon and that it forms a distinct proportion of cases of genitourinary tuberculosis.

Tuberculosis of the epididymis is exceedingly common, and when it is primary and limited to this organ radical removal has resulted in cure in about 40 per cent. of the cases. From the epididymis the vas and seminal vesicles and prostate may become involved and later general tuberculosis, or, infrequently, the bladder and kidneys.

Tuberculosis of the tubes is exceedingly common; the process frequently involves the ovary and peritoneum and occasionally the uterus.

Primary tubal tuberculosis rarely leads to involvement of the kidney, except in cases of such widespread tuberculosis that surgical treatment of the kidney would be excluded. In all these forms of genitourinary tuberculosis the great benefits to be derived from the outdoor, open-air and general hygienic treatment must be recognized as of great importance and must be taken advantage of and insisted on in all cases. This becomes very clear when we remember that even in the cases in which there is no evidence or history of a primary focus elsewhere in the body, nevertheless such a primary focus probably does exist and remains even after the radical surgical removal of the focus in the genitourinary tract.

Tuberculosis of the kidney is a common disease. It occurs at all ages, but is most common from 20 to 40 years of age. Women seem to be more often affected than men, about two to one, although on this point there is a divergence in statistics. It occurs in postmortem statistics more frequently as a bilateral lesion.

Report of 12,732 autopsies at Kiel showed that of the cases of renal tuberculosis 62.3 per cent. were bilateral and 37.6 per cent. unilateral.

The *clinical* evidence is different. In Kroenlein's cases 92 per cent. were unilateral and 8 per cent. bilateral. Israel found but 8.3 per cent bilateral. Facklam found but 9 per cent. bilateral. Kuemmell found but 12 per cent. bilateral. Israel concludes that if our attention is called to these cases early we should find 90 per cent. of them unilateral.

In surgical clinics in which kidney fixations are limited to suitable cases tuberculosis of the kidney usually furnishes the largest percentage of any single pathologic process, being more frequent than stone or tumor; tuberculosis of the kidney is frequently found associated with other evident tuberculosis, as tuberculosis of lung, cervical glands, bladder, bones and joints, and genital tuberculosis, as epididymis or tubes. Kidney tuberculosis is sometimes associated with other pathologic conditions, as an old gonorrheal invasion or renal calculus and hypernephroma.

SYMPTOMS.

Renal tuberculosis can and does undoubtedly run at times a silent course, without giving rise to any symptoms even when a single kidney has been entirely destroyed. The most common symptom is an increased frequency of urination. This frequency is seldom very great, unless there is present some degree of cystitis. There may be some pain on urination, but this, where marked, usually speaks for an involvement of the bladder. The patient may notice that the urine is cloudy; pus in the urine and blood in the urine are important symptoms.

In probably 25 per cent. of the cases blood is noted as a symptom. Sometimes a large quantity is found, even sufficient to fill the bladder and to cause an attack of renal colic by obstructing the ureter. More often it is slight or even microscopic in amount; pus is present in varying amounts, not infrequently there being a mixed infection with staphylococcus albus or colon bacillus. In advanced cases the segregator or ureteral catheter may show nothing but pus coming from the ureter, the kidney secreting substances being almost entirely destroyed.

Pain in the kidney region and radiating to the bladder along Poupart's ligament may be present, either as a sense of soreness and a dull ache or an acute attack of renal colic simulating stone and due to the plugging of the ureter with blood or tuberculous débris. When a perinephritic involvement occurs the tenderness and pain characteristic of such a process are present in the costovertebral angle. Temperature occurs in a fair proportion of cases (of the tuberculous type with slight elevation in the evening), or again as exacerbations which come on at intervals and last several days.

In well-marked cases, as in tuberculosis elsewhere, the general evidences of grave constitutional disease, i. e., loss of strength and weight and secondary anemia, are present. A swelling in the kidney region, due either to an enlargement of the kidney or to a perinephritic process, is present in a limited percentage of cases.

The differential diagnosis must be made between other inflammatory lesions of the urinary tract, simple pyelitis and pyelonephritis and kidney stone and neoplasm, and such rare and obscure lesions as the so-called essential kidney hemorrhage and polycystic degeneration of the kidney.

In my own clinic I find that the cases of simple pyelitis and pyelonephritis have been few as compared to the tuberculous cases and the other pathologic processes simulating tuberculosis. As a rule, the simple pyelitis and pyelonephritis sustain about the same relationship to tuberculous infections of the kidney as far as onset and history are concerned as does acute osteomyelitis of the upper end of the femur to hip-joint disease, i. e., there is not infrequently the history of the existence of a preceding suppurative process elsewhere, as a carbuncle, a furuncle or an acute infective process, as a grip or pneumonia, or an infection of the lower urinary tract, and then the sudden acute onset of the symptoms, with chill, temperature and pain, enable one to make the differential diagnosis between an acute suppurative infection and the chronic process of the tuberculosis. When an acute suppurative infection occurs in a tuberculous kidney, which has not been previously recognized, the diagnosis may be difficult or impossible.

In my own work I have been especially interested in the differential diagnosis between tuberculosis, stone, tumor, polycystic kidney and essential kidney hemorrhage. We have been confronted with this problem in sixty cases, in which the pathology was later determined by operation. Of these, twenty-eight proved to be stone, seventeen proved to be tuberculosis, ten proved to be hypernephroma, four proved to be essential kidney hemorrhage, one proved to be polycystic kidney, unilateral.

All of these pathologic conditions may present the following symptoms in common: 1. Blood and pus in urine. 2. Pain in kidney region and attacks of kidney colic. 3. Tenderness in kidney region. 4. Enlargement in kidney region. 5. Bladder symptoms more or less marked. 6. Constitutional symptoms, loss of weight, etc. 7. Slow onset of symptoms and chronic course.

We have attempted to make the differential diagnosis by means of: 1. Careful history and physical examination. 2. An x-ray examination. 3. A careful examination of urine for tubercle bacilli, etc. 4. A cystoscopic examination of the bladder. 5. Cryoscopic examination of the blood.

In the ordinary case, when this differential must be made, we adopt this line of procedure:

1. Several x-rays are obtained, which show satisfactory differentiation of the structures. If stone is found the diagnosis is made; if no stone is found, stone is excluded as a probable diagnosis in our work. The percentage of error in negative cases has been but 3 per cent.

2. In these negative cases, then, the urine is carefully examined for tubercle bacilli. If found, the diagnosis is made; if not found after a week's careful search, tuberculosis is not excluded, because we have failed to find tubercle bacilli in about one-half of our cases.

3. The bladder is then examined and if bacilli have been found the ureters are catheterized to determine whether the process is limited to one or involves both kidneys and the mouth of the ureter is carefully examined.

4. In the cases in which the x-ray is negative and the examination of the urine for tubercle bacilli is negative, and when an enlargement of the kidney exists, the diagnosis of hypernephroma is most probable. We have been able to make this diagnosis in five or six cases on these grounds.

5. We make a cryoscopic examination of the blood, not of the urine, with the belief that in hematuria if the process is limited to one kidney we shall find the normal freezing point of — 0.56; if both kidneys are involved and kidney insufficiency exists, the cryoscopic examination will show — 0.60 or above.

Following the above methods, in this list of sixty operations we have been able to make the correct diagnosis in more than fifty cases. In only six or eight were the operations begun as exploratory operations.

TREATMENT.

The treatment of tuberculosis of the kidney depends to-day entirely on the facts as to whether one or both kidneys are involved. As already pointed out, in 90 per cent. or more, the process is an infection through the circulation and is limited to one kidney.

In these cases, there is but one operation to consider and that is nephrectomy, the removal of the diseased kidney. If, because of the existence of a mixed infection, the patient's condition is such as to make an immediate nephrectomy out of the question, a nephrotomy with drainage should be made simply as a palliative operation and with the understanding that, as soon as the condition of the patient permits, a radical operation of nephrectomy should be made.

A resection of the kidney is to be practically discarded from consideration. The multiple foci, which are disclosed by a careful examination of all the tuberculous kidneys removed at operation, show how useless such a procedure is.

When both kidneys are involved, the treatment must be nephrotomy and drainage in cases in which there are large abscesses, and the fresh-air and outdoor treatment of widespread inoperable tuberculosis.

OPERATIVE TECHNIC.

In uncomplicated and early cases a nephrectomy for tuberculosis presents few difficulties. An oblique incision, extending from a point a finger's breadth below the last rib and just external to the erector-spinæ muscles, is carried downward and outward to a point a finger's breadth above the crest of the ileum. This divides the skin, superficial fascia, latissimus dorsi muscle and the layers of the lumbar fascia down to the fatty capsule of the kidney. This incision runs about parallel with the lumbar nerves and these, as a rule, can be avoided. The kidney is entirely freed from its surroundings and brought outside of the wound. The ureter is ligated separately from the vessels. The vessels are double ligated with middle-sized catgut. The inside of the mucosa of the ureter, distal to the ligature, is cauterized with pure carbolic acid.

For a time it was believed that it was very necessary to remove the entire ureter. More recent experience seems to show that this is unnecessary and that the ureteral mucosa, even though involved in the disease, gradually recovers after the removal of the primary foci in the kidney proper. The external wound is closed with the exception of a cigarette drain carried down to the stump of the ureter and the great vessels. This is removed at the end of forty-eight hours.

RESULTS.

I know of no more satisfactory results in the whole field of surgery than those which are obtained by an early nephrectomy in unilateral kidney tuberculosis. With this fact established, it becomes our duty to make it more widely known and to plead for early recognition and early radical operation for kidney tuberculosis.

On the seventeen patients which I have handled surgically for tuberculosis, 21 operations were performed, 12 nephrotomies, 7 nephrectomies, 1 opening of a perinephritic abscess and 1 resection. Nephrotomy was made in most of the cases in my earlier work. None of these proved curative. The same result followed in the single resection which was performed. The histories of the seven nephrectomies have been very satisfactory. They have all recovered from the operation, except one, and have been apparently entirely cured.

The one fatal case is a case in which a nephrotomy had been done with a slight temporary improvement. A nephrectomy, which was performed later, was made extremely difficult by the extensive perinephritic inflammation, which resulted from the first operation. An ill-advised attempt was made to remove the kidney with its capsule. This made the operation very bloody and very prolonged, the patient dying of shock within a few hours. Since that time we have saved similar patients by removing the kidney from within the fibrous capsule, when the perinephritic adhesions are dense, which is a much easier and safer procedure and seems to give very satisfactory results.

DISCUSSION.

Dr. Van Buren Knott, Sioux City, Iowa, stated that the old surgical conceptions and ideas of the pathology of renal tuberculosis gained from postmortem records are being constantly revised by antemortem or operation statistics. It was commonly believed only a few years ago that kidney tuberculosis was an entirely hopeless affection; that surgical treatment did not offer anything very satisfactory in the way of results; and time and again the pendulum swung back and forth between medical and surgical treatment. Postmortem records nearly always showed bilateral disease of the kidney, when in nearly every instance kidney tuberculosis is primarily unilateral. A descending infection may and very frequently does occur; the bladder becomes involved, and if the case is neglected and is allowed to go on for an unreasonable length of time, it is only a question of months before the second kidney is involved. This being true, the duty of the physician is very clearly outlined. The patient should have not only dietetic and hygienic treatment, as recommended by the physician, but surgical treatment as well.

The diagnosis is of extreme importance. It is only by early diagnosis that proper treatment can be instituted. This is another one of the diseases where the only treatment that can accomplish anything is that which is instituted early. The use of the cystoscope in these cases is of the greatest assistance, although frequently cases are encountered where its use is very unsatisfactory. With a tubercular contracted bladder, the use of the cystoscope at times is extremely difficult, and catheterization of the ureters, or of one ureter, has, in some instances, been found to be a difficult procedure. In some cases it has been necessary to expose the second kidney, making a definite diagnosis of the condition existing in the kidney known to be diseased. As a rule, it is a reliable method of determining the condition of the other kidney before attempting to do a nephrectomy on the diseased kidney. Dr. Knott had one unsatisfactory occurrence. After removing the kidney the patient's condition became alarming and death ensued. The second kidney, which had been supposed to be healthy, was found to be in an advanced stage of tuberculosis. So that even inspection of the second kidney does not always lead to the safest results.

As to cystoscopic pictures of the bladder, he has been able many times to find conditions made plain by finding advanced congestion in the neighborhood of the ureter. Dilatation of the orifice of the ureter is typical of kidney tuberculosis, and in most instances the catheterization of that ureter will not be necessary, as such a dilated orifice speaks sufficiently loudly for tuberculosis of the kidney.

Nephrotomy, he believes, was justly condemned by Dr. Bevan as a palliative operation. The attempt to conserve any portion of the kidney tissue is a mistake. He has had two cases in which attempts to conserve partially tuberculous kidneys by resections of a small portion of the viscus were followed by results which made resection of the whole kidney necessary. He emphasized that the treatment of tuberculosis of the kidney is now in the critical stage and that the future of this treatment will depend on the early recognition of the disease and the immediate institution of a radical operation, which in all instances should be nephrectomy when the disease can be located and is confined to one kidney.

Dr. Howard A. Kelly, Baltimore, said that his experience with tuberculosis of the kidney covers about 49 or 50 personal cases, and a considerable additional number of cases in the hands of his associates, Drs. Hunner and Cullen. He has found that tuberculosis of the kidney is a very common affection. He was interested to know the frequency in which tubercular lesions in other regions are found in these cases. Very often the patient has had a tubercular joint lesion of an obscure or a manifest nature; or there have been lesions in the glands or in the bones; or, sometimes, a latent pulmonary lesion. The history of these cases always should be gone into very carefully.

In women the disease is almost always primary in the kidney. Dr. Kelly has never met with a case suggesting an ascension from the bladder to the kidney, nor does a clearly proven case exist in the literature. In men, where bladder tuberculosis originating from a testicular tuberculosis is common, as compared to the frequency of bladder tuberculosis without kidney involvement in the woman, it may occur. It is possible to picture an involvement of the vesical end of the ureter leading to stricture of same and a consequent hydroureter above, thus producing conditions favorable to the tubercular ascension. While granting the possibility of such an occurrence, it must be kept in mind that clinical autopsy and experimental facts all speak for its rarity. In women it is always of great importance to investigate the condition of the genital organs. There is a common association between renal tuberculosis and tuberculosis of the uterine tubes and even of the uterus itself. He has had several such cases. The first two or three came as surprises, but lately he has been looking out for them very carefully. Dr. Kelly had a patient who had a pelvic tumor and tuberculosis of the right kidney. When he opened the abdomen he found a disseminated tuberculosis, the peritoneum looking as if it had been peppered. He took out the much-involved pelvic organs, after which he did a right nephro-ureterectomy. The association of tuberculosis with hydronephrosis is remarkable, particularly with stone. The first case of this kind he saw was a patient whose physician had removed a kidney stone. Several years later she had tuberculosis in the same kidney and it was removed.

As to the diagnostic signs, it is not the common ones which demand attention, but the uncommon ones. Pain is not always a satisfactory sign, for the patient may have pain in the wrong side. The size of the kidney may be misleading, because a normal kidney may be hypertrophied. Tubercle bacilli in the urine can be demonstrated in some cases of pulmonary phthisis, without renal involvement, particularly if the twenty-four hours' urine is examined. Dr. Kelly also referred to a tubercular case in which the woman had been advised to have the wrong kidney taken out because it had a large ureteral orifice on that side. He has a patient with tuberculosis of the urinary tract, who had a golf-hole orifice on one side and a large red ureteral orifice on the other. He felt sure that the former was the affected side, but when he cut into the kidney there was no disease. He then cut into the other kidney and there also was no disease. It was a case of primary tuberculosis of the bladder with these interesting signs.

He noted the very common occurrence of stricture of the ureter in these cases. In two early cases he was misled and sent the patient back to her physician with a diagnosis of stricture of the ureter. She undoubtedly had the stricture, but it was due to tuberculosis of the ureter above the strictured portion. Nephrotomy, he said, may be necessary as a temporary means to relieve the patient, but nephrectomy must follow. Resection should not always be urged because Morris took out a kidney on one side and then the patient developed tuberculosis in the other kidney. He did a nephrectomy and four years later the patient was in good health and able to work at service.

Dr. Willy Meyer, New York City, believes that tuberculosis of the kidney is a very common disease, much more common than it has been thought to be in former years. The principal point is to make the correct diagnosis. It must be of value to have some more or less distinct clinical symptoms which will cause the surgeon to suspect the disease. Pain is a very important sign; but, according to his experience, a far more significant symptom is that of frequent urination with tenesmus (sometimes appearing in distinct attacks) not only during the day, but during the night. If a younger patient says that he has frequent urination, both during the day and during the night, that he has had renal colics with pus and blood in the urine, he at once suspects primary renal tuberculosis, especially if there has been no gonorrhea and the patient has never been subjected to intravesical instrumentation. If tubercle bacilli are then found in the urine, the diagnosis is established. In order definitely to locate the disease, he insists in these cases on cystoscopy. Of course, the bladder is here frequently contracted and irritable, and there is a great amount of catarrh, etc., but, if one will take the trouble to carefully irrigate the viscus, preferably with a weak bichlorid solution, after due cocainization, he will soon be able to introduce a sufficient amount (three ounces) of boric-acid solution to permit of a cystoscopy. If in such a case he sees the mouth of one ureter healthy and that of the other injected, or rather ulcerated, he diagnoses unilateral descending tuberculosis. He considers this cystoscopic picture the most important pathognomonic sign in determining which side is diseased. It is of greater value than unilateral pain.

Dr. Meyer fully agrees with Dr. Kelly that pain is sometimes misleading. In one of the cases observed by him, the patient complained of constant pain on one side, tubercle bacilli were found and he thought the diseased kidney would be on the painful side. He did cystoscopy and there was pronounced ulcerative catarh. The picture was blurred. He treated the man for a week or two and then repeated cystoscopy. He found an ulcerated ureteral mouth on the other side, and the one corresponding to the painful side was healthy. On the basis of this finding he diagnosed primary renal tuberculosis of the opposite side and cut down on that kidney. It proved to be the seat of the disease and was removed. The patient is well to-day.

Catheterization of the ureters can be dispensed with in the majority of these cases. If recurrent attacks of pain are located on the side that shows the ulcerated mouth of the ureter, and if tubercle bacilli are found, the diagnosis is still more firmly established. Therefore, in suspicious cases, the cystoscope should be used as soon as possible. If the mouth of one of the ureters is ulcerated, there is a descending tuberculosis. If the mouth of neither ureter is ulcerated, but if pyelonephritis is made out by urinary analysis, and tubercle bacilli are found, there is an ascending tuberculosis

The kidney which is diseased should be removed, and the earlier it is removed, the better. Then send the patient out into the country, into the mountains, if possible. Let him benefit from hygienic régime, after he has had surgical treatment.

Dr. Joseph Ransohoff, Cincinnati, stated with regard to ascending tuberculosis of the kidney that there is such an occurrence as the result of a primary disease of the vesicles, the prostate or the testicles, with secondary involvement of the bladder. Otherwise it is always a descending tuberculosis. A non-motile bacillus can not travel up stream. Tuberculosis of the testicle is always an ascending tuberculosis from the epididymis running toward the prostate. He said that he understood Dr. Kelly to say that very frequently in women tuberculosis of the kidney is associated with tuberculosis of the genital tract. There is one thing that calls attention to the fact that tuberculosis is descending when coming primarily from the kidney, and that is, that tuberculosis of the kidney occurs as often in women as it does in men, and in women it could not have any association with the genital tract and become an ascending affection. Tuberculosis of the kidney must be kept absolutely separate and distinct from tuberculosis of the genital tract, in the male as well as in the female. Dr. Ransohoff said that some years ago he read a paper before the American Surgical Association on the treatment of tuberculosis of the kidney, and called attention to the fact that nephrotomy ought not to be done as a final operation. On that occasion he did report one case of partial resection, and that patient had done well since, but it ought not to be done often. Quite recently he had a tubercular kidney for removal. One of his assistants suggested that he save the kidney, taking out only the one pole that was involved. He made a section of that kidney and there were minute deposits in the cortical substance that would certainly have given rise to trouble later on.

He invariably makes a laparotomy to determine whether or not the other kidney is there. If it is in the right place, feels right and is of the right size, he takes it for granted that the kidney is doing its work right. If it is not, God help the patient. Even catheterization of the ureters and cryoscopy will fail sometimes to aid in making a correct diagnosis. The individual case must decide what operative procedure is to be adopted.

Dr. E. W. Lee, New York, referred to the case of a young man who two years ago received an injury to the testicle while playing football. Dr. Lee removed both testes because they were tubercular, and now that young man is suffering from tuberculosis of both kidneys, which has been demonstrated conclusively by catheterization of the ureters.

Dr. L. L. McArthur, Chicago, thinks it a mistake to let the dictum go out that all tubercular kidneys should be removed as soon as the diagnosis is made. That is, it would be a mistake to advise or to counsel the profession to remove kidneys affected with a severe mixed infection, from which the patient has been suffering for weeks, and is in practically a septic condition. Under these circumstances it is perfectly justifiable, and this is borne out by practical experience, to first drain that kidney, let the fever subside and restore the patient to good condition. Then perform the nephrectomy, but not until then.

The New Public Hospital at Berlin.—The great Rudolf Virchow Hospital is nearing completion. The total expense has been nearly $5,000,000. There are 57 separate buildings with 3,400 rooms, exclusive of the basement. The capacity of the hospital is 2,000 beds, divided as follows: 564 beds in the 11 buildings of the surgical service; 500 beds for the 10 buildings for internal medicine; 95 each for the obstetric and gynecologic wards; 11 beds for septic cases; 24 for the quarantine building; 34 for the diphtheria pavilion; 120 in the 4 infectious diseases pavilions; 18 beds for unruly patients, and 374 for males with venereal disease, with 146 for female cases. Some of the buildings have been in use for some time, the museum even before Virchow's death.

SODIUM CITRATE IN INFANT FEEDING.*

A. C. COTTON, M.D.
CHICAGO.

The infant deprived of the breast must, in relation to his feeding, be regarded as a pathologic problem. That this statement is axiomatic is shown by the fact that more earnest work has been bestowed on infant feeding during the past twenty years than on all other pediatric subjects combined. That the problem is still unsolved the high relative mortality and later morbidity of artificially fed infants bear constant witness.

The six essentials of Cheadle, enunciated by that observer some time in the '80s, bear witness that the essential requirements of an artificial food for babies were broadly understood 20 years ago. Quoting from memory, they are briefly as follows: 1. Sterility. 2. Antiscorbutic property. 3. Quantity. 4. Some animal constituents. 5. Form suitable. 6. Constituency. Much has been learned since Cheadle by amassing clinical results and observations. Meanwhile the deductions from *a priori* reasoning have proven unsatisfactory for the simple reason that so little was known of the physiology of infant digestion. Latterly the premises from which we reasoned have been proven, almost without exception, to be incorrect.

Thus the great American experiment known as the exact percentage method of feeding required that the baby's diet should consist wholly of cow products and water, so modified in its five gross constituents as to coincide quantitatively with similarly named constituents of average breast milk. One other ingredient only was allowable in this feeding mixture, viz., some alkalin solution, as lime water, sodium bicarbonate or magnesia. This dogma, which in connection with laboratories established throughout the country had almost become a cult in infant feeding, was practically based on seven assumptions, which have recently been proven erroneous, to wit:

1. The qualitative similarity in breast and cow's milk of the lactose, fats, albuminoids, proteids and their chemical combination with the milk salts.
2. The claimed alkalinity of breast milk in contradistinction to the acidity of cow's milk.
3. The possibility of a synthetical substitute for breast milk from cow products alone.
4. The claim that cereals were not allowable because indigestible in the infant's secretions and that they induced dyspepsia and intoxication by acting as decomposing foreign matter.
5. That cereal gruels were no more efficient in the prevention of dense milk coagula than dilution with plain water.
6. That HCl played no part in the digestive process until later infancy.
7. That the important proteid content of the baby's food could be made up from the non-coagulable whey albumin of cow's milk.

The elucidation of facts in refutation of these premises is due to the earnest work of a number of men, prominent among whom as members of this association may be mentioned Chapin on cereal gruels and gastric development, Kerley on milk reaction and alkalinization, Shaw on HCl secretion in infants, Stern on milk fats, Southworth on the art versus the science of infant feeding, Morse on acidified milk and buttermilk feeding, and the recent unsurpassed work in chemistry of milk by Van Slyke and Hart at Geneva. Most of these contributions have enriched our literature and become familiar to all. The subject is still a broad one. I disclaim any intention of attempting in this limited paper to deal with it *in toto* and indulge in these preliminary observations merely to emphasize the fact that no royal road to successful feeding by exact mathematical formulas has yet been found. Nor do I wish to convey the impression that I would belittle the value of attempts at accuracy in determining the component parts of the infant's dietary.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Great credit is due and will ever be associated with the name of Dr. Rotch as the founder of a system which has not only served as an hypothesis for tentative feeding, but has stimulated to greater accuracy and more careful clinical observation and recording of results than was possible by any other method. As an enthusiastic advocate of the so-called American method, I am on record frequently both at home and abroad. I may be pardoned if I suggest that the tendency in general is too much along the line of the refinement of mathematical formulas to the neglect of the obvious importance of gastric development along normal physiologic lines.

The spectacle of a marantic infant with persistent curds in the stools, though cow proteids have been reduced to the extreme limit of attenuation by dilution with water, is a familiar one. So, also, too commonly in evidence is the child fed long, but not nourished, on whey proteids and cream whose gastric vigor has not progressed beyond that of early infancy.

Important as the rôle of carbohydrates and fats in infant development may be and difficult as the problem of properly dealing with fats is, it is to the management of the proteids that I beg to call your attention in the few minutes allowed. Their importance in the nutrition of the child needs no emphasis, as it is universally accepted both theoretically and clinically.

The intolerance of the infant's digestive organs to cow proteids, so widely different from those for which they were intended, is also well known. Of the many methods in vogue for the establishment of toleration of these refractory curds the one most common, unfortunately, is their quantitative reduction by dilution far below percentages absolutely necessary for the development and growth of the child. In fact, the common advice to infant feeders on percentages of milk in recognition of its refractoriness is either to restrict the proteid percentage far below that which is known to obtain in average breast milk (as though Nature would commit the absurdity of elaborating the necessary amount of proteid from even a less quantity when presented in the more obstinate form of cow casein), or to substitute the non-coagulable proteids of whey.

In either case Nature is cheated of her absolute demands. The pathetic malnutritional results of low proteid feeding, both immediate and remote, are too familiar to us all to need further elaboration. Aside from this slow starvation and stunted growth with its diminished resistance to intercurrent disease from insufficiency of nitrogenous food, abundance of proteids is demanded in a coagulable form for the normal development of the gastric function, as ably shown by Chapin and corroborated by a host of clinical observers. This the infant gets at the mother's breast in proteids which clot on admixture with the gastric contents in soft, flocculent, semi-solid coagula which readily pass the pylorus in a form suitable to intestinal digestion and absorption.

The important question, then, in feeding cow's milk is not how to reduce the proteids and sustain life, but how to *increase* the proteids and maintain unimpaired digestion. Buttermilk has been tried; acidulated milk has been tried; admixture with gruels has been tried; koumiss, matzoon and kephir milk have been tried; the addition of various alkalies is much in vogue; all with varying degrees of success, and each measure has its ardent advocates. That the question is not yet settled this diversity of opinion amply indicates. It is still an open field, and the cry that no chemical tampering with the milk should be encouraged need deter no one, since it is proven beyond dispute that cow's milk, however modified, is not a natural food for the human infant. The more orthodox observers of the original laboratory percentage modification have from the first chemically tampered with the milk in the addition of lime water, sodium bicarbonate, etc., in the mistaken notion of humanizing the mixture by rendering it alkalin. That we reached further than we intended in our administration of alkalies and secured toleration of the curds through neutralization of the normal gastric acids does not lessen the evils of inhibition of those digestive processes which can occur only in an acid medium.

Since deductive methods from *a priori* reasoning have thus far failed of a satisfactory solution of this problem, let us welcome inductive methods conducted along rational lines, since massed clinical evidence must ever be the tribunal before which all methods must come to trial. Whether *secundus artem* or *secundus scientiam,* it is the greatest number of babies who live and thrive and resist disease that demonstrates the merits of their hygiene.

AUTHOR'S EXPERIENCE.

It is with the firm conviction that sodium citrate, through its inhibition of dense coagulation of cow's milk in the presence of an acid and rennin, may prove valuable in the solution of the proteid problem that I present a brief résumé of my experience with this agent.

More than two years ago in a personal letter from one of my assistants, Dr. J. W. Vanderslice, who was studying abroad, my attention was called to this use of sodium citrate. The reports from Dr. F. J. Poynton's clinic at Great Ormond Street, London, from which the writer as an eye witness drew his conclusions, seemed sufficient to justify a careful consideration of this new method of overcoming some of the obstacles in the adaptation of cow's proteids to infant digestion.

Rather cautiously, I began prescribing the citrate in cases in which varying milk mixtures had been used with poor success. Later, as I found that infants would tolerate a larger proportion of the milk in the feeding mixture when citrated than by any other modification known to me, I used it more boldly, so that during the past two years I find a record of its employment for a longer or shorter period in more than 50 cases in both hospital and private practice. I have here, by the courtesy of Dr. J. D. Merrill, a report of 8 cases in which she has carefully observed its effects for a considerable time, also by the courtesy of Dr. Vanderslice a history of 29 cases reported by him at different times to the Chicago Pediatric Society. In addition to this I have read carefully Dr. Shaw's[1] report of 22 cases, making a total of 112 cases embracing nearly all conditions from simple dyspepsia to marasmus and ranging in age from the new born to adults who have suffered from milk dyspepsia.

---

[1] Shaw: Arch. of Pediatr., March, 1906.

Sodium citrate being very soluble in water, the method of employment is simple, as follows: An aqueous solution is ordered containing from 1 to 5 gr. to the dram. A quantity of this solution is furnished the mother or nurse with instructions to add to the baby's bottle immediately before feeding enough of the solution to represent 1, 2 or even 3 gr. of the citrate to each ounce of milk in the feeding mixture, according to the prescriber's idea of the requirements. The feeding mixture may consist of varying dilutions of milk with water or gruel with the addition of cane or milk sugar, with or without cream. No alkalies are added, the sodium citrate used being a neutral salt. A most noticeable feature in this method of feeding is the large proportion of milk in the feeding mixture that the infant will tolerate without evidence of gastric disturbance or the appearance of any considerable amount of undigested casein in the stools. In fact, the stools of babies fed on citrated milk have come to be regarded by Drs. Merrill, Vanderslice and myself as positively characteristic, being firm enough to show form on the diaper, free from fecal odor and homogeneous in color and consistency. The slight tendency to constipation mentioned by Dr. Vanderslice I have observed in a number of cases in which I attributed it to the low percentage of fat in the food, consisting of equal parts of milk and water or even one part of milk to two of water. In but few instances have I observed this constipation where the fat contents of the mixture equalled 3 per cent.

One indication for the increase of the sodium citrate, even in some cases to as high as 3 gr. to the ounce of milk, is vomiting of curds. Another indication is the appearance of curds in the stools, care being taken to exclude indigestion from excess or intolerance of fats. Of the stools, J. H. Salisbury, professor of chemistry, to whom they were submitted, reports as follows:

> Three samples of the feces of infants fed with milk modified by the addition of citrate of sodium were examined. The feces were yellow, of a moderately firm consistence and remarkably homogeneous. On microscopic examination a few round masses, probably calcium soaps, could be seen scattered through the otherwise very fine débris. In two specimens short crystals of soaps could be detected. No free fat was found. On treatment with acetic acid more or less acid crystals could be observed and in one specimen this was especially marked. Chemical examination of one specimen for proteids was negative.

The duration of the administration of the sodium citrate, as well as the quantity employed, varies considerably in different cases, the purpose being to bring the baby's feeding up toward whole milk as rapidly as possible. As toleration is established the amount of citrate is reduced to one, to one-half and to one-fourth of a grain per ounce of milk until it can be discontinued. It happens not infrequently that the citrate is profitably resumed on the recurrence of signs of indigestion. In but 6 cases have I felt obliged to discontinue the citrated milk and adopt other methods of feeding. Some of these were among my early cases which, if occurring later, would possibly have received a more persistent treatment with citrated milk.

In consideration of this subject three questions naturally arise: 1. Is the employment of sodium citrate any better than other methods of rendering cow proteids tolerable and digestible? 2. Is its employment harmful? 3. In what manner does it act?

In answer to the first I would say that this method seems to allow a more rapid increase in the proportion of milk ingested than any other known to me. Moreover, the frequency of relief from milk indigestion on the addition of the citrate and the favorable reports from all whom I have known to give it a thorough trial are not without significance. In regard to its harmfulness no case of citrated milk feeding has been brought to my attention in which there appeared to be cause for regret bcause of the employment of this method.

Concerning its manner of action in a chemical sense there appears to be some difference of opinion. Professor Salisbury, above quoted, to whom the question was submitted, states as follows:

> Citrate of calcium is insoluble in water, but dissolves readily in solutions of the alkali citrates. It is to be presumed, therefore, that when a solution of sodium citrate is added to milk which contains calcium in combination with casein a reaction would occur producing a sodium combination of casein and an insoluble calcium citrate. The latter would dissolve on the addition of an excess of sodium citrate. It is to be presumed, therefore, that the milk treated with citrate of sodium contains a sodium compound of casein and calcium citrate held in solution by the presence of sodium citrate. Such milk would not yield a curd containing an excess of calcium, but the calcium would be found in the whey as well as in the curd. The experiments of Dr. R. Aibinder do not contradict the theory of Poynton that sodium citrate acts by separating the calcium from the casein, thus rendering it less easily coagulable. Sodium citrate would react with hydrochloric acid solution to form sodium chlorid and citric acid. The decomposition would not be complete but so nearly so that a large quantity of sodium citrate would neutralize nearly all the free hydrochloric acid of the gastric juice. Too large an amount of sodium citrate in the milk might, therefore, interfere with the digestion of proteids in the stomach. Such digestion might occur in the intestine from the action of the pancreatic juice.

The physical behavior of citrated milk *in vitro* is obvious and may be demonstrated in a simple manner suggested by Wright and Poynton, who first exploited this method of feeding. Into each of two test tubes containing equal quantities of milk (to one of which sodium citrate has been added) drop a given quantity of liquid rennet and dilute HCl. In both milks coagulation occurs; with this difference, that the citrated milk clots less promptly and the resultant curd is softer, less dense, more nearly resembling the curd of breast milk.

DR. ALLIN'S EXPERIMENTS.

My assistant, Dr. F. W. Allin, as the result of more than a hundred careful comparisons, has obtained the following results:

Materials Used.—Ordinary dairy milk was used in these experiments. Wyeth's liquid rennet was used for curdling agent, which was always added last. A 1 per cent. hydrochloric acid solution and 4 per cent. sodium citrate solution was used. Two drops of HCl in 5 c.c. milk equals .025 per cent. Five drops of sodium citrate solution equals .25 per cent. One grain of sodium citrate to the ounce of milk would be .20 per cent. The gruels were standardized to one ounce of flour or oatmeal to the quart of water and cooked three hours in a double boiler.

Conditions.—The experiments were all performed at 40 C. in glass test tubes. The milk was used as whole milk or diluted with water, flour gruel or oatmeal gruel. The dilutions made were two-thirds, one-half, one-third, one-fourth, one-eighth milk.

Results.—All experiments were repeated many times. The accompanying summary is a tabulation of results. The time recorded is the average of the results.

CONCLUSIONS

1. Sodium citrate in .25 per cent. or more retards, and very high percentages will inhibit coagulation.
2. The presence of HCl hastens coagulation.
3. Diluting milk generally retards coagulation.
4. Gruels appear to have little or no effect in retarding coagulation more than water when the citrate is used.
5. The coagula of citrated milk are softer, smoother and more jelly-like or more flocculent than those of milk not thus treated.

EXPERIMENTS WITH CITRATED MILK.

WHOLE MILK.

Milk. c.c.	Liquid Rennet. m.	HCl. 1% m.	Sod. Cit. m.	Time. min.	Curd.
5	5	2	0	3	Solid, firm.

5	5	0	0	5	Solid, firm.
5	5	0	5	15	Solid, soft.
5	5	2	1	4	Solid, firm.
5	5	2	2	4½	Solid, firm.
5	5	2	3	5½	Solid. firm.
5	5	2	4	7	Solid, softer.
5	5	2	10	12	Flocculi, no curd.
5	5	10	0	1	Solid. hard.
5	0	20	0	. . . . .	No curd.
5	0	20	5	. . . . .	No curd.
		HCl. 5%			
5	0	1	0	1 hr.	0
5	0	2	0	"	0
5	0	3	0	"	0
5	0	4	0	"	0
5	0	5	0	15	Small flocculi.
5	0	10	0	15	Few flocculi.

DILUTED MILK.

Milk.	Liquid Rennet.	HCl. 1%	Sod. Cit.	Dilu-ent.	Time.	Curd.
⅔	5	2	0	Water.	3	Solid, firm.
⅔	5	2	5	Water.	5	solid.
⅔	5	2	0	Gruel.	3	Solid, firm.
⅔	5	2	5	Gruel.	20	No change.
½	5	2	0	Water.	3	Solid or co'rse granular.
½	5	2	5	Water.	7	Solid.
½	5	2	0	Gruel.	3	Solid, firm.
½	5	2	5	Gruel.	20	No change.
½	5	2	2½ c.c.	. .	0	No change.
½	5	0	0	Water.	12	Soft, solid.
⅓	5	1	0	Water.	5	Granular.
¼	5	2	0	Water.	5	Hard, granular.
¼	5	2	5	Water.	5	No change.
¼	5	2	0	Gruel.	4	Granular or solid.
¼	5	2	5	Gruel.	0	No change.
⅛	5	2	0	Water.	6	Small solid.
⅛	5	2	5	Water.	0	No change.

The simplicity of this method commends it, especially in dispensary and out-patient practice where the mother's demand for "medicine" for the baby's dyspepsia may be met by the standard solution of sodium citrate to be administered in teaspoonful dose in each bottle of the feeding mixture. In private practice it furnishes another rational method of infant feeding.

1485 Jackson Boulevard.

The province of the doctor is to relieve the sick and suffering and to subordinate to that first object of his calling the obtaining of a financial reward for his labor. "Do your duty and then collect your money" is the physician's motto. "Be sure of your money before you deliver the goods" is the perfectly proper motto of the business man.—John B. Roberts.

THE TREND OF PEDIATRIC OPINION CONCERNING THE ARTIFICIAL FEEDING OF INFANTS.*

THOMAS S. SOUTHWORTH, M.D.
Attending Physician, Nursery and Child's Hospital, New York City Children's Hospitals and Schools, Physician Out-Patient Department Babies' Hospital.
NEW YORK.

The artificial feeding of infants elicits to-day from our profession an even keener interest than at any time in the past. As a practical science it is making continual progress. A satisfactory working hypothesis having been established some years ago, the spirit of inquiry is now engaged in proving this structure and examining the principles on which it rests. Those portions which do not stand the test are being rapidly replaced by sounder material. Our labor in this direction is far from completed, but it may not be amiss at this time to review somewhat briefly the trend of pediatric opinion concerning certain of these important questions and to recount some of the recent advances.

Foremost among these, because the most fundamental, has been the recognition forced on us by the study of the comparative anatomy and physiology of mammalian species, that milk must be the basis of an infant's food, because milk proteid is alone capable of forming, with the secretions of the stomach, the soft solids requisite to such development of that organ as to fit the infant later for subsistence on the mixed diet of the adult. Cow's milk is the only milk at present obtainable commercially in sufficient quantities to meet the needs of the really appalling number of infants who for valid or in-valid reasons are deprived of their normal food from the maternal breast. Some of our chief problems of infant feeding have centered, therefore, about our efforts to adapt this milk of a foreign species to the infant's digestion. The inherent differences in the caseins of cow's milk and human milk and the size and character of their curds formed in the infant's stomach enhance the difficulties. Practically all methods of preparing milk for the infant which are of real value, including some of proprietary origin, have the common purpose of enabling the infant to digest successfully the casein of cow's milk in sufficient quantities to thrive. Viewed in this light, the claims of the advocates of different methods of feeding are reconciled, since they are but seeking by different routes the same goal.

STARCHES.

Discussion concerning the ability of the young infant to digest starches is giving way to a realization that the utility of cereal decoctions as diluents does not depend so much on whether the starch itself can be digested as on the mechanical subdivision of the casein curd and the absorption of the vegetable proteids which such cereals contain. If the starch itself causes any difficulty or such difficulty be feared, it can be readily transformed into soluble carbohydrates by previous dextrinization. A gruel which has been so dextrinized is no longer a solution of starch, but a mixture of soluble sugars with gums and vegetable proteids. However, what is commonly called starchy indigestion and starchy non-digestion are two very different things. The former, indigestion caused by starchy foods, is deleterious when it occurs, but the non-digestion and non-absorption of starch granules is often more or less present even in adults wherever starch forms a part of the food. The mere presence of a starch reaction in the stools does not prove that the bulk of it has not been digested. If these decoctions of starch-bearing substances serve the primary purpose for which they are added to an infant's milk, the presence of undigested starch granules need not necessarily be more hurtful than that of cellulose and other undigested or unabsorbed residues.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

USE OF BARLEY WATER.

Barley water, which is more commonly employed to make the curds of cow's milk smaller and more permeable by the digestive secretions, probably accomplishes this by its viscidity, which is partly due to its peculiar proteids. The addition of these vegetable proteids to the food may at times be no negligible quantity in determining the nutrition of the infant. This is not to be construed as advocating the feeding of infants entirely or even largely on cereals. While certainly not suited for indiscriminate use in all cases, the employment of cereal diluents for many children who have shown special difficulty in digesting the casein of cow's milk is now quite common in the hospitals of which I have knowledge. Barley water and barley gruel are much too elastic terms. Unless these are to be dextrinized the quantity of flour for young infants should not exceed one full teaspoon to each pint of water. The value of stronger cereal additions to the milk during the later months of the first year is now scarcely disputed.

CASEIN.

A new interest has been awakened in certain phases of feeding through a better interpretation of the behavior of casein in the infant's stomach and of the purposes and results of adding various alkalies to the food. Applying to these problems the most recent investigations, we have ceased to add alkalies on general but vague or unknown principles. Stated as simply as possible, these methods have resolved themselves as follows:

Casein readily combines with either alkalies or acids, and in doing so forms substances which have different chemical and digestive properties. Casein as it is found in cow's milk fresh from the udder is now called calcium casein, because the casein is chemically combined with calcium or lime. It would simplify matters if the term bicaseinate of calcium were applied to this casein of fresh cow's milk, for on adding limewater to such milk the casein takes up still more lime from the limewater and forms a new compound, which might be called caseinate of calcium. The difference between these compounds of casein and calcium in fresh milk, and in milk to which limewater has been added to the point of alkalinity with phenolphthalein, is as distinct as the difference between bicarbonate of soda (baking soda) and carbonate of soda (washing soda). Good fresh cow's milk requires the addition of from 60 to 80 per cent. of its bulk of limewater to make it alkaline to phenolphthalein and to change all the normal bicaseinate of calcium into this new compound, which is not coagulated by rennet.

When we add from 5 to 10 per cent. of limewater, as is customary in infant feeding, to a mixture containing but a small amount of actual milk, the casein will be wholly or almost wholly changed into the form which can not be coagulated by the rennet ferment of the infant's stomach until the secretion of acid has removed the extra calcium; but when the same percentages of limewater continue to be used, as the mixture is strengthened by additional quantities of milk, there begins to be present in the food more of the coagulated casein than the limewater is able to saturate. So that when we add from 5 to 10 per cent. of limewater to the weak milk mixtures suitable for a newborn infant we first give milk which is not curded, and later by gradually strengthening the food without raising the quantity or percentages of the lime water we supply increasing amounts of casein which will form a curd in the stomach.

OTHER ALKALIES.

Other alkalies added to fresh cow's milk will also form combinations with the casein and alter its digestive properties. Such are sodium carbonate, potassium carbonate, magnesium hydroxid, sodium bicarbonate and sodium citrate. The first three of these probably form caseinates of calcium and sodium, of calcium and potassium and of calcium and magnesium. Sodium carbonate and potassium carbonate are usually added in such quantity as to just about completely saturate the casein and prevent its curdling. But when we use bicarbonate of sodium we often add it in such quantity as not only to saturate the casein, but its unused portion remains in the food and acts as an antacid in the stomach. It not only modifies the digestive properties of the casein like the others, but its antacid properties which are not fully neutralized by the milk may be used to modify any natural or abnormal acidity of the stomach. It is especially in vomiting cases where the stomach is too acid from the production of abnormal acids that bicarbonate of sodium finds one of its best fields, although I believe that at times the more soluble compound with sodium is more readily absorbed than that formed with limewater.

The inhibition of the coagulating power of rennet on such casein as is saturated by the addition of these alkalies is, however, but temporary, for on the addition of an acid like gastric juice, in quantity sufficient to neutralize and remove the extra alkali, the normal properties of coagulation by rennet are restored.

On the contrary, when citrate of sodium is added to milk a very different chemical change takes place from that which accompanies the employment of the usual alkalies, for with citrate of sodium the casein is decalcified and a sodium casein is produced, which rennet can not thereafter affect, so that acid must form with it only the type of curd which acid would form with it outside of the body. My experience with the employment of from 1 to 2 grains of citrate of sodium to each ounce of actual milk in the feeding, as recommended by Poynton, has been sufficiently favorable to warrant the belief that it is worthy of a more extended trial in selected cases than it has yet apparently received in this country

EFFECTS OF ACIDS ON MILK.

I can only refer here to the further effects of acids on fresh milk or alkalinized milk in freeing the casein entirely from its combination with alkaline bases and as a second step forming acid compounds with the freed casein. Such are the curds formed when natural souring takes place, or when acid is added, of free casein, casein lactate and casein hydrochlorid. When rennet acts on the milk either before or conjointly with the acid, producing calcium paracasein (junket), the acid transforms this first into free paracasein and then into paracasein lactate or paracasein hydrochlorid.

PERISTALSIS AND INTESTINAL DIGESTION.

The exceedingly valuable experiments of Prof. W. B Cannon, of Harvard, have reconstructed our views of intestinal processes. Many of us were taught that peristalsis consisted in successive waves of contraction of th circular muscular fibers of the intestine, which advanced the food mass, aided by shortening of the longitudinal fibers. Professor Cannon, by watching through the *x*-ray screen the movement of food masses containing bismuth, has shown that circular contractions occurring simultaneously at short distances in the small intestine cause a segmentation of the food mass. These contractions then relax and are followed by other contractions midway between the former, dividing the masses at new points, but causing them to reunite at the previous points of segmentation, and this is repeated until finally the masses are swept by a peristaltic wave further along in the bowel.

These observations throw new light on the mechanics of intestinal digestion and the method by which the chyme is churned and mixed with the digestive secretions in the intestine. We are all doubtless familiar with certain stools of infants which present the fecal mass divided into what I have elsewhere designated as flakes about the size of a flattened oat. These, while ordinarily termed curds, are often small masses of perfectly digested fecal matter. They are most typical in the stools of very young infants, securing only small amounts of milk from the breast, where a small fecal residue is accompanied by considerable quantities of mucoid secretion. For their formation I have heretofore been unable to secure a satisfactory explanation. In the light of Professor Cannon's work, it is readily explicable that these flakes are formed by segmentation in the small intestine, but the fecal residue being small and the intestinal secretion relatively large they are eventually surrounded by the latter so that subsequent fusion into larger masses is prevented.

Again, no better explanation could be offered us of the injurious influence on intestinal digestion of flatulent distension of the bowel. It is almost inconceivable that a much distended small intestine should be capable of producing a normal segmentation of the chyme or of bringing the food masses into repeated contact with the entire area of secreting surface. While improper digestion of the food leads to the formation of the gas which distends the bowel, this is but another instance of a vicious circle which must be broken before proper intestinal digestion can be resumed.

PERCENTAGE FEEDING.

Now that the furore which followed the introduction of the American system of percentage feeding and milk modification has subsided sufficiently to allow us to estimate calmly its value, certain conclusions are forced on us. The first of these is that in scope and elasticity it far surpasses all previous efforts at artificial feeding because it enables us, as never before, to control intelligently and with approximate accuracy the constituent elements of the food for each individual infant. On the other hand, it is no detraction whatever from the merited laurels of those who have devised, developed and popularized this system, to say that we should now realize that no method of artificial feeding can ever safely or properly replace the physiologically adapted milk of the human breast among the great mass of our population. Artificial feeding is unquestionably attended with more danger than breast feeding. The two alternatives should not be offered lightly to the prospective mother as though they were of equal value. While bad breast milk, if it be really bad, is worse than good artificial feeding, the nervously and socially overwrought mother does not make up the vast bulk of the motherhood of our country. Breast milk which is good and plentiful, or which can be made so with a little rational attention, far surpasses as a food that which is furnished by the cow and is infinitely beyond the combinations of the manufacturing chemist.

INFANT FOODS.

Whether the harm done by infant foods which claim to equal mothers' milk has been in any degree offset by the wide dissemination of their often faulty directions for infant feeding might perhaps be debatable. Parents who employ these on their own responsibility and physicians who recommend them should inform themselves, however, concerning their composition and understand that infant foods are but rarely safe or of value for any considerable period by themselves; that they are subtle and prolific causes of rickets, scurvy and malnutrition, and that many, nay most of them, are really successful only when combined with fresh cow's milk and its indispensable proteids, to which the child so fed owes its proper development, although the food manufacturers claim the credit.

CLEAN MILK.

The reason why cow's milk is the best commercial substitute when we are forced to resort to artificial feeding has already been stated. To be suitable for this purpose it must be fresh and pure. The movement for a clean milk supply which had its origin with Dr. Coit, in Newark, N. J., is yearly gaining headway over the country and must be accorded a place among the great life-saving measures of recent years. We have not yet reached such perfection that pasteurization or some modified form of sterilization is not usually necessary during the warm months of the year unless the circumstances be exceptional.

One of the objections most commonly raised to the introduction of modified milk feeding among the poorer classes has been that it would be impossible to teach the mothers properly to prepare the food. My personal experience has amply disproved this. If the physician himself thoroughly understands the steps to be taken and is willing to take the time not only to write out his directions, but to explain them fully, excellent results may be obtained. But this is not enough; he must later make the mother tell him in her own words what she is doing, for by this method only are serious errors and omissions corrected. With time and patience most mothers may be taught to prepare food suitable for their infants, using inexpensive instruments of precision. But they must also learn that such feeding requires supervision and change with the growth or temporary indisposition of the child. It is to ignorance of this fact, or to the inability on the part of the physician to maintain control, that artificial feeding owes its greatest dangers.

As a rational outgrowth of the movement to secure clean milk has come the conviction that the less milk and cream are manipulated the better they are digested by infants and consequently that the use of top milks of easily varied richness in fat is preferable to cream and milk mixtures. The fat content of food prepared from top milk can be more easily controlled. Possibly the only exception to these statements is where both the requisite purity and exactness of dispensing can be obtained through milk laboratories.

THE AMOUNT OF FAT.

Evidences of proteid indigestion are more readily comprehended than those of too high fat. For a not uncommon type of such stools Dr. Holt's simile of scrambled egg is an excellent one which I have had frequent occasion to verify. The recognition should be more general of the fact that high fat is capable of causing constipation as well as a fat percentage which is too low, and also of the futility and probable danger of pushing the fat much beyond 4 per cent. for any child. This, then, constitutes one of the risks in the use of cream and milk mixtures, owing to the wide inaccuracies which may result from the variableness of all centrifugal creams, and the absolute impossibility of making any close estimate of the fat content of such creams without the use of the Babcock machine. Even commercial creams from the same source vary daily very considerably. I have in mind a recent instance in which the child's food had been made with cream and milk in the country, but on return to the city a cream was secured marked "special." This I found to contain 40 per cent. of fat. The previous formula made up with this actually contained 11 per cent. of fat, and only a fortunate habit of inquiring into details prevented the serious disturbance which inevitably would have followed. In other instances the persistent refusal of the child to take a suitable quantity from its bottles, or the otherwise unexplained presence of mucus in the stools, has led to similar discoveries.

FEEDING FORMULÆ.

Methods of obtaining milk formulæ and rules for the preparation of such food are now accessible in several standard text-books. Those, however, who are satisfied with securing a few stock formulæ will seldom attain to genuine success in infant feeding, for this includes the reclaiming of the marasmic as well as the conduction of the normal infant. Those who have no clear conception of the purposes subserved by the various component parts of the food nor of the indications for varying these have no clue to the solution of difficulties as they arise, and readily fall victims to the seductive claims of the patented foods in the hope that in some mysterious way they may be helped out of their troubles.

EXPLANATION OF DIFFICULTIES.

Many of the difficulties experienced arise, I believe, from the non-comprehension and non-application of certain broad principles. Surely, enough has been said recently by many writers concerning the necessity of feeding infants as individuals, but the distinction between the fairly normal infant and the sick child, which includes the child hitherto fed on condensed milk or various commercial foods, as well as the child with disturbed digestion or nutrition from any cause, is not sufficiently understood. The usual schedules for feeding at different ages may apply to the fairly normal child whose digestive powers have been developed, more especially when such feeding was begun at birth; but to endeavor to make an infant with disturbed or untrained digestion take the amount of casein in the food usually scheduled for its age is folly. Trial must first be made with much lower formulæ, and particular attention given to determining whether the difficulty lies with the digestion of the fats or of the proteids. The stools, the weight chart, and the behavior of the infant are the triad with which successful feeding must be conducted. In my wards of the Nursery and Child's Hospital the stool of each feeding case is brought to the cribside in a basin to be studied in conjunction with the range of the weight chart, inspection of the infant, and the nurse's report before changes are made in the food. Such changes must not be made too frequently and allowance should be made for minor variations of both weight and stools. In the case of an infant with bad stools the restoration of digestion as evidenced by better stools and greater comfort is infinitely more important than an immediate gain in weight. It is, in fact, a prerequisite to such gain. It is now rather generally accepted that fairly normal young infants whose artificial feeding is begun soon after birth will, while they are being trained to digest their new form of casein, usually take a rather high proportion of fat to proteids (3 to 1), since the fat supplies an easily absorbed source of heat and energy. Not all, however, will tolerate so high a proportion. When proteid digestion has been established, the proteid percentage should be pushed up somewhat more rapidly than was formerly deemed advisable, in order that there may be furnished adequate proteid for proper nutrition.

On the other hand, I think there is an increasing tendency in the sick wards of infants' hospitals to employ level fat and proteids (i. e., formulæ made from plain milk). These are better borne by sick children who have fever and are also better assimilated in malnutrition cases in which the infants have suffered from varied attempts at feeding. Fat starvation does not occur with these level mixtures as it does with almost fat-free infant foods or condensed milk which is relatively poorer in fat than good average fresh milk. There is a considerable number of such infants who can not take the high fat ratios of the common formulæ, although after good growth has been established on level formulæ cautious attempts may be made to raise the fat ratio a little higher.

Somewhat more advanced infants with fairly good digestions take the usual schedule proportions of fat and proteids (2 to 1) well, but much of what might be called subnutrition may be avoided after the sixth or seventh month by pushing the proteids somewhat above 2 per cent., a percentage which until recently has been considered a fair one at this period. The lack of formulæ between 4.7.2 and pure milk 4.4.4, except for such as could be made by the partial dilution of the milk, has been noticeable in some hospitals and milk dispensaries.

Finally, too much emphasis can not be given to the statement that the most carefully planned percentages are often fruitless because of overfeeding or improper intervals. Far less difficulty would be experienced in the feeding of infants if closer attention were given to the well-established rules governing the proper intervals and the quantity. No rules are so frequently violated even in hospital practice. It is especially noticeable in the tendency to overfeed undersized infants. Many poorly nourished infants are fed at intervals which correspond to their weight or apparent age. At the same time, despite or perhaps owing to their failure to gain, the quantity is repeatedly increased to equal or even to exceed that of a normal infant until the stomach can neither contract properly on its contents nor secrete sufficiently for their digestion. Energy and material which should be used for growth are thus expended on this undue labor of digestion, if indeed there can be any proper absorption from the partially digested mass. By giving at longer intervals and in smaller quantities (which may be made more concentrated as the stomach regains its tone) excellent results are produced in these cases.

807 Madison Avenue.

WHOLE MILK VERSUS LABORATORY MILK.*

A. McALLISTER, M.D.
CAMDEN, N. J.

Whatever opinion is entertained as to the intrinsic value and practical utility of cows' milk modified by the percentage method, as practiced in special laboratories, there is unanimity in pronouncing the plan the best yet advanced for securing constancy in the constituents of a substitute infant food. It admits of accuracy to a small fraction as no other known method does. It renders possible, from day to day, feedings practically invariable as to their proteids, fat and sugar.

In short, the laboratory product is an ideal substitute for mother's milk, theoretically. But if the accumulated experience in infant feeding has established one thing beyond another it is that we are not up against a theory but against a condition—a condition as stubborn as any met in the practice of medicine.

This condition is unnatural, morbid and confusingly variable. Infants are born anatomically and physiologically built for the warm mother breast and virile mother milk. Any other method and product in the dining-room appointments of this new arrival must be classed as abnormal. He may or may not take the imposition kindly. Frequently his whole being is thrown into a state of revolt and ordinary conciliatory measures may prove of no avail.

Physicians are generally consulted only in cases demanding extraordinary measures. A large proportion of these are already complicated by more or less functional, if not, indeed, organic, disease. No fast rules for feeding can be laid down, because no two cases are quite alike. Every infant deprived of its normal nutriment is distinctly a law unto itself.

As in applied therapeutics, so in infant feeding, the very multitude of plans and products that have been indorsed in the past is indicative of great problems yet unsolved. Ten years ago we sought an easy solution of the entire question in sterilization. Later we took up laboratory milk. The present plea is for a return to raw cow's milk.

In the subject of this paper the term laboratory milk is made to include every form of milk other than fresh raw cow's milk or fresh cow's milk diluted and warmed to about 100 F.

Clinically, milk modified by the percentage method has proved applicable only for temporary use in certain cases to bridge an emergency. For general use or for prolonged feeding in any one case the results have disappointed its most sanguine advocates. Economically its utility is even more restricted. The cost of such milk, the lack of proximity to a laboratory and the necessity for change of the prescription from time to time place the product within the reach of only a favored few among the wealthy.

Sterilized and pasteurized milk are now practically within the reach of every family, but no physician of large experience recommends either, especially not the former, for continuous feeding. They are employed now only for one of two reasons. When the milk supply is not above suspicion in freshness and purity, or has been condemned, recourse must be had to one of the above methods until a proper milk can be secured.

Again, in the event of serious disturbances in the alimentary canal it is the part of prudence to allow only sterilized milk while such disturbances are being removed. But this practice is now recognized as only offering to the belabored digestive organs a product more difficult of digestion. A better procedure is to allow only sterile drinks or thin gruel while the digestive tract is being cleared and then resume feeding with largely diluted milk. On the same principle and for the same reasons peptonized or partially digested milk is advantageously employed.

A synthetic breast milk is still to be found. Our nearest approach to it is laboratory milk viewed merely from the point of its chemical composition. From every point it is far from a duplicate of mother's milk. The natural milk emulsion has been destroyed in the process of centrifugalizing. The life-quickening principle which distinguishes milk from every other liquid food has been destroyed by heat. The product is a mixture of dead milk constituents.

The wire in your scrap pile may be an exact duplicate of that stretching overhead, but it is only a mass of inert metal, while that overhead is described as live. In much the same sense milk that once had the sanction of eminent authority is now recognized as scrap-pile goods. The life-quickening principle is not in it. It is dead. Fresh milk is not a dead liquid. Like the vital fluid tissue, the blood, of which it is an immediate product quite as much as nerve tissue, fresh milk is much alive.

FRESH COW'S MILK IDEAL SUBSTITUTE FOOD.

The ideal, natural, practical and economical substitute food for infants is fresh cow's milk. Drawn and handled with such care as to cleanliness and health as is required by laboratory standards, cooled at once and then kept at a temperature below 50 F., cow's milk possesses all the important vital constituents. It is a live fluid. These constituents give to milk the characteristics described as freshness or sweetness, and which are not found in stale, sterilized or laboratory milk.

Freudenreich ascertained that this freshness has a distinct germicidal power, typhoid and cholera bacilli being destroyed by fresh raw milk. This power he found absent in milk which was well kept, yet four or five days old, and in milk which had been heated to a temperature exceeding 130 F. Too little attention has been directed to securing the benefits of this native virility in cow's milk. We need as large a proportion of it as can possibly be secured to the infant. In country practice infants have the advantage of these benefits. The greater difficulties of infant feeding in city practice are at least in a measure due to the absence of these benefits. The difficulty is further heightened by the addition of deleterious qualities to milk through careless, dilatory and otherwise unscientific handling.

Each year makes the successful feeding of city infants with cow's milk a less difficult problem. Much is to be gained by persistent agitation. The laity can have a milk supply 100 per cent. better than now provided by simply demanding it. The first cost need not be materially increased. With our constantly improving railroad facilities, due to the popular clamor for rapid transit, the question of greatly improved milk transportation is no longer difficult.

Much has been accomplished along educational lines by our bacteriologic and milk laboratories. Methods by which cow's milk may be kept fresh and not only safe but superior without the addition of a preservative are not unknown to the average dairyman. He will employ these methods when the consumer demands it. There is no doubt that at the present time inferior milk is marketed by pasteurizing it. The term is high-sounding and with some is synonymous with excellence. The laity need to learn that good milk properly handled not only does not require sterilization, but is positively made less valuable from the dietetic point of view by such process. Milk so treated is not freed from the products of bacterial growth. It is not absolutely sterile, and even if it were would require careful handling to guard against subsequent infection and multiplication of bacteria.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

The subject of federal control of the system of milk production and distribution is receiving increasing attention. But, as in all matters closely related to the public health, education will do more good than legislation. Reynolds, of Chicago, has made a strong plea for twelve-hour milk. He pointed out that such milk is worth more for infant feeding than milk twenty-four hours old, while milk thirty-six hours old is not only of little food value, but positively harmful to young and delicate children.

The milk bottle is popular, but at the present time is too frequently looked on as a positive guarantee of freshness and purity. With all its advantages the bottle is the source of much mischief and positive harm. Much of our city milk is bottled at the milk depot, and not a little in the milk wagon on the streets. Milk bottled at the dairy permits of great leisure in transportation, and much of the milk when it reaches the consumer is in a state of semi-decomposition. Public sentiment needs an awakening along this line.

Most of the milk consumed in Camden comes from Salem and Burlington counties, New Jersey. The best quality is "certified milk" and gives general satisfaction in the feeding of infants.

580 Federal Street.

DISCUSSION

ON PAPERS OF DRS. COTTON, SOUTHWORTH AND MCALLISTER.

Dr. D. E. English, Millburn, N. J., said he realized that bringing up a child in the country is a very different thing from keeping a child from dying amid the horrors of a great city. The working woman's baby in the country sits on the kitchen floor and uses his crust of bread or bone to wipe up the floor or scratch the dog's back, and then puts it into his mouth and does not get sick. Why? Simply because the mother has not time to bother with him. He is not taken up and fed until his stomach is entirely empty and he is really hungry. Then he is fed until his stomach will not hold any more, put into a clothes-basket and set out of doors under a tree, where he sleeps for three hours or more. It is an hour, or perhaps two hours, longer before he is again fed. This means that the baby's stomach has been distended with food, and that it has had time for digestion, evacuation, contraction and rest before the next feeding. This is the true idea of infant feeding. A baby's digestive organs can not always digest the same amount of the same kind of food in the same number of minutes. Again, a baby will not be healthy and happy unless he earns his living, any more than will an adult. A baby earns his living by the cool bath, the air bath, by exercising his limbs, by crying, and by being exposed to cool, fresh air.

Dr. John Lovett Morse, Boston, said that, in feeding babies, when breast milk can not be secured the idea is to give a food suitable to the baby's digestion. It is an advantage to know what one is working with and not to work with unknown quantities. This knowledge does not prevent trying all kinds of infant feeding, nor the use of good common sense. He believed with Dr. Southworth that milk can be modified at home, not only by the rich but by the poor. The only question is whether it will be modified correctly. He did not agree with Dr. Southworth in preferring top milk to milk and cream. His experience and that of many men accustomed

must not be made too frequentl and allowance shoul be made for minor variations of both weight and stools In the case of an infant with bad stools the restoration o digestion as evidenced by better stools and greater com fort is infinitely more important than an immediate gai in weight. It is, in fact, a prerequisite to such gai It is now rather generally accepted that fairly norm young infants whose artificial feeding is begun soo after birth will, while they are being trained to dige their new form of casein, usually take a rather hi proportion of fat to proteids (3 to 1), since the fat su plies an easily absorbed source of heat and energy. N all, however, will tolerate so high a proportion. Wh proteid digestion has been established, the proteid p centage should be pushed up somewhat more rapi than was formerly deemed advisable, in order t there may be furnished adequate proteid for pro nutrition.

On the other hand, I think there is an increasi sary [illegible] in the sick wards of infants' hospitals to em something othe [illegible] proteids (i. e., formulæ made from ment of percentages of the [illegible] put into an infant's stomach in [illegible] borne by sick children feeding patient, who must be treated as w[illegible]imilated in malfood. The general hygienic management of the baby is most important and determines to a great extent its ability to overcome various digestive disorders.

Dr. R. B. Gilbert, Louisville, Ky., said that the extent to which bacterial flora get into the milk is well known, and no matter what the percentage of proteid may be, these bacteria are apt to occur. The presence of colostrum in milk is also an important matter, for the milk of one pregnant cow in a herd of twenty will so infect that milk that it will be injurious to the baby. He has demonstrated that the pancreas is fairly well developed in babies and has wondered that we have been taught that the pancreas does not secrete anything in early life. It is as well developed as any part of the intestinal apparatus. He thought that Dr. Cotton's suggestions relative to sodium citrate would help to solve many difficulties in milk modification.

Dr. T. W. Kilmer, New York City, said that the baby should be supplied with that which it has a right to demand, breast milk, and the physician ought to know what breast milk contains. The average general practitioner does not have this knowledge; therefore, he is unable to feed babies successfully. He should know how much fat, proteid and sugar he is giving the baby.

Dr. A. H. Wentworth, Boston, said that apparently it is desirable for the infant to take as much proteids as it can get. So far as he knows, all the evidence is otherwise. Chittenden and other authorities seem to show that the excess above a certain amount only throws more work on the various organs and serves no helpful purpose. Men who have done most for infant feeding in Germany are unanimous in the opinion that babies need very little beyond one per cent. of proteids in their infancy, that they get sufficient quantity in that amount to nourish them perfectly. In regard to distending the stomach, he thinks that overdistension of the muscles is deleterious.

Dr. Effa Davis, Chicago, mentioned a series of five cases in which the children were all doing well on the ordinary milk mixture, but when they were put on the sodium citrate modification all remained stationary in weight for six weeks and then began to lose, notwithstanding the fact that they were taking two and three times as much milk as usual. When they were taken off the treatment it took them all ten days to regain their normal equilibrium. All are now on the ordinary modification of milk and gaining. It is clear, therefore, that all babies do not do well on the sodium citrate feeding.

Dr. J. W. Vanderslice, Chicago, said that sodium citrate solution has been used in a large number of cases for three years by men who have a very wide clinical experience. Sodium citrate advocates say that they use the simple method, believing the method to be more simple than the modified

epsom or rochelle salts, and the fluid fecal matter was collected in clean porcelain dishes with covers. This *material was examined in a perfectly fresh condition.* The series consisted of 50 patients, and the infections noted are tabulated as follows:

Total cases with intestinal parasitic infection, 18.

Amœbæ	11 cases
Uncinaria duodenalis (ova)	4 cases
Tricocephalis dispar (ova)	4 cases
Strongyloides intestinalis (ova)	3 cases
Opiscorcus sinensis (ova)	1 case
Ascaris lumbricoides (ova)	1 case
Hymenolepis nana (ova)	1 case

From the preceding figures it is evident that plural infections were present. They were as follows:

	Cases.
Amœbæ and *Strongyloides*	2
Amœbæ, Ascaris, Uncinaria and *Tricocephalus*	1
Amœbæ and *Opisthorcus*	1
Amœbæ alone	7
Total	11
Strongyloides and *Amœbæ*	2
Strongyloides alone	1
Total	3
Uncinaria and *Hymenolepis*	1
Uncinaria, Amœbæ, Ascaris and *Tricocephalus*	1
Uncinaria alone	2
Total	4
Tricocephalus, Amœbæ, Ascaris and *Uncinaria*	1
Tricocephalus alone	3
Total	4

Contrary, then, to the report I had received, amebas are not infrequently found in the stools of natives of Siam. Moreover, it can not be said that these amebas are of the non-pathogenic type, if such there be. At least three of the patients examined were suffering from a true amebic dysentery, others had more chronic or subacute intestinal symptoms.

In all 50 cases were examined, of which 18, 36 per cent., presented infections with intestinal parasites (exclusive of monads which were present in at least 60 per cent. of all the cases). Of the 18 cases of infection, 11 showed amebas, a percentage of over 61 per cent.

PERCENTAGE OF INFECTED CASES OUT OF A TOTAL OF 50.

	No.	Per ct. of infected cases.	Per ct. of total cases.
Infected cases	18	....	36
Infected with *Amœbæ*	11	61.1	22
Infected with *Uncinaria*	4	22.2	8
Infected with *Tricocephalus*	4	22.2	8
Infected with *Strongyloides*	3	16.6	6
Infected with *Opisthorcus*	1	5.5	2
Infected with *Ascaris*	1	5.5	2
Infected with *Hymenolepis*	1	5.5	2

The only conclusion that one may draw from these figures is that infection with animal parasites is widespread in Siam (the patients being from various districts and a few were Chinese), and that amebic infection is very common. It is my intention to make more complete records on this subject as time and opportunity allow.

So far as I can discover, *Opisthorcus sinensis* has not been previously reported from Siam. *Hymenolepis nana* has been reported from Siam by Rasch.[1]

Palpation to Find Position of Fetus.—B. G. Snyder, in the *Canada Lancet*, June, 1906, in discussing the position of the fetus *in utero*, emphasizes the value of external palpation, as a convenient, simple method, which practically eliminates the danger of infection. It is of most value before labor, but the progress of labor can be judged just as accurately after a little practice by this method as by repeated vaginal examinations. Lastly, it compels a physician to study the different positions of the child and their relations to the birth canal and thus makes him a more intelligent obstetrician.

THE TREATMENT OF PURPURIC CONDITIONS AND HEMOPHILIA.*

JOHN W. COE, M.D.
NEW YORK CITY.

It is not the purpose of this paper to discuss the numerous theories concerning the etiology and pathology of these interesting conditions, for the multiplicity of ideas is the best evidence of the obscurity which still surrounds them, but to outline a course of treatment which has been beneficial.

Since A. E. Wright, in 1891 and 1893[1] and in subsequent articles, advocated the use of the chlorid of calcium to hasten the coagulation of the blood, many patients with hemorrhagic tendencies have been greatly helped by it while with others it seems inert. The preparations of the adrenal gland are also of value in many cases.

Boggs,[2] in 1904, demonstrated that the lactate of calcium had the same accelerating effect on coagulation as the chlorid.

Wright[3] and Paramore,[3] in 1905, published the results of a series of experiments in which they used the lactate of calcium and the carbonate of magnesium, as well as the chlorid of calcium. They found that the coagulation time was more uniformly influenced by the lactate than by the chlorid and that the magnesium salt had a similar accelerating effect. These were merely laboratory tests, some of them made on normal individuals, others on patients with various ailments, and the drugs were not used therapeutically.

During the past few months I have treated several patients with the lactate of calcium, with results that seem worth recording.

Case 1.—A well-known physician, aged 53, who has one of the largest general practices in New York, is a member of a hemophilic family. His grandfather and father were bleeders, as are also a sister and a son. In the patient the tendency to bleed appeared when he was ten years old. The bleeding has always been most profuse from the nose, but he has bled much from skin of the face and head and from the mucous membranes of the mouth. The nasal hemorrhages have often been prostrating and have been increasing in severity and frequency, often requiring plugging once or twice a day.

Needless to say, this patient has had the best of local treatment by specialists and, as he says, has taken barrels of calcium chlorid and the adrenalin preparations with no benefit. During the autumn of 1905, the bleeding was more profuse than ever before and the patient's large practice was a burden to him.

Blood Examination.—On December 17, the red blood cells were 3,680,000, white cells, 5,000, and the hemoglobin 70 per cent. The stained specimens showed pallor of the red cells, moderate variations in size and shape with a number of large cells. The plates were decidedly below normal as judged from a stained specimen. The differential count of the leucocytes was normal and need not be given in detail.

Treatment and Result.—At that time the patient was bleeding practically every day and very profusely. On December 21, when bleeding, fifty grains of calcium lactate, dissolved in water, were taken and in half an hour the hemorrhage ceased with no other treatment.

During the next week, that is until December 29, twenty grains of this drug were taken three times a day. There was no bleeding, but once or twice there was slight oozing from the nose, which stopped in a few seconds.

[1] British Medical Journal, Dec. 19, 1891; July 29, 1893.

[2] Deutsche Archiv. für klin. Med., March 15, 1904, p. 539.

[3] Lancet, Oct. 14, 1905, p. 1096.

No calcium lactate was taken from then until January 10, and, after a few days, moderately severe attacks of epistaxis began again.

On the evening of January 10 there was a profuse hemorrhage and the patient took sixty grains of the calcium lactate. The bleeding stopped almost at once.

By January 14 there had been a gain in weight of five pounds since starting the treatment, and the condition of the blood steadily improved. The experiment of stopping the lactate for several days was repeated on several occasions, always with the same result. During the last two months the patient has taken about once a week fifty grains of the lactate and has been comparatively free from bleeding. Occasionally there has been a hemorrhage of moderate severity, but always soon controlled. Previously, the putting of the head down, as in the act of lacing the shoes, would usually be followed by epistaxis, often lasting for hours. For months now, much more violent exertion than this has caused no discomfort. Examination of the blood a short time ago showed a perfectly normal condition.

The coagulation time in this patient, as measured by Wright's tubes, was never very high, being between six and seven minutes, but it is invariably lowered from a minute to a minute and a half by a full dose of the lactate. This effect is produced in an hour at the most and persists for about a week.

Probably no one would be so optimistic as to expect a cure of such a marked case of hemophilia running through four generations, but the improvement has been so marked and, to date, so constant that, compared with his previous condition, the patient is well.

This man's son, 23 years old, began to have frequent attacks of epistaxis at the age of 16. The hemorrhages have never been very profuse, but have made him quite uncomfortable, as they began without the slightest warning while he was walking along the street or at the table, etc. No records of his case have been kept, but during the past five months he has taken an occasional dose of the lactate, about forty grains once a week, and his condition has been much better than for years.

Case 2.—J. S., male, aged 17, student, family history entirely negative.

History.—This boy began to have frequent, profuse attacks of epistaxis when five years old. These have recurred at irregular intervals to date, at times lasting for hours and causing him to faint. The gums and mucous membrane of the mouth at times ooze blood, but there has been none in the urine or stools. The severe attacks have usually been accompanied by numerous hemorrhagic areas over the legs, arms and beneath the eyes. When thirteen years old he began to have occasional rheumatic pain in the knees. This trouble has frequently recurred, usually with slight fever for a few days, and is associated with an outbreak of petechiæ on the legs. His physician, Dr. E. W. Perkins, states that practically all the time for years the boy has had well-marked purpuric eruptions somewhere on the body. The slightest bruise is invariably followed by ecchymosis. Four years ago, after having a molar tooth pulled, he bled profusely for three hours.

Examination.—When first seen, March 6, 1906, there was a moderate number of petechiæ over both legs and several larger areas on the thighs. The mucous membranes of the mouth showed several small purpuric spots and there were marks on the trunk, as from bruises.

Blood Examination: This showed: red cells, 4,680,000, white cells, 6,000, hemoglobin, 80 per cent. The coagulation time was four minutes. A stained specimen showed a normal differential count and that the blood plates were very few. Later the plates were counted and were found to be 29,000 to the cubic millimeter.

Treatment and Results.—The patient was given fifteen grains of calcium lactate three times a day for a week. At the end of this time the coagulation time was unchanged, being four minutes. The purpuric spots were much faded and no new areas had developed. A severe blow on the right knee had resulted in no ecchymosis.

The calcium lactate was stopped on March 20. On March 27 a profuse eruption appeared on the thighs and legs, associated with pains in both knees. The patient was given salicylic acid and sodium bicarbonate with fifteen grains of calcium lactate every morning. Four days later he reported that the improvement had been very rapid, much more so than from any previous attack. The purpuric eruption had nearly disappeared. He was then given Fowler's solution and iron with fifteen grains of calcium lactate, twice a week. From this time until May 14, that is, for more than six weeks, he remained free from bleeding, with the exception of an occasional spot on one or the other leg, and all the time he was playing and exercising as vigorously as other boys. He then neglected to have the prescription for the calcium lactate refilled and two days more than usual having elapsed between the doses, he was awakened on the morning of May 14 by the most severe attack of epistaxis for months. This lasted for over an hour.

The coagulation time on this date was four and one-quarter minutes and the blood plates very few.

It is interesting to note that in spite of the decided hemorrhagic tendency in this boy the coagulation time is at all times a low normal, the variations in health being between three and six minutes by Wright's tubes.

Case 3.—A. H. G., aged 31, male, married, instructor in Latin. Family history entirely negative.

History.—The patient has never had any serious illness. When about six years old he bled profusely for hours after having a tooth pulled. Two years later frequent attacks of epistaxis began. The bleeding occurred from either nostril or from both simultaneously, and often continued for hours, requiring packing. Such attacks have recurred frequently to date and last autumn became more numerous than ever before, being only from four to seven days apart for weeks.

Any slight bruise, as even the rubbing of a dress-suit case on the legs, is always followed by ecchymotic areas. The last of December he developed a carbuncle on the upper lip. At the operation, performed in one of the large hospitals in the city, the bleeding was not extreme, but at the subsequent dressings, profuse hemorrhage occurred. He was given calcium chlorid with some benefit. A few days after leaving the hospital the epistaxis recurred.

Blood Examination.—When referred to me by Dr. D. B. Brinsmade, Jan. 23, 1906, the red blood cells were 4,372,000; white cells, 12,000, and the hemoglobin 70 per cent. A stained specimen showed marked pallor of the cells. The blood plates were very few and small in size. This point has also been noted in all subsequent specimens examined. On one occasion, when counted, they were 22,000 to the cubic millimeter. The differential count was normal. Before beginning treatment the coagulation time was eight and a quarter minutes. This promptly fell to seven minutes, where it remained.

Treatment and Result.—The patient was given twenty grains of the lactate of calcium three times a day for a week and after that forty grains twice a week. On February 5 he returned to work feeling as strong as ever and had no tendency to hemorrhage, even on blowing the nose

On February 13 medication was stopped and not resumed for a month. Then oozing began on three occasions from the left nostril, but ceased after taking sixty grains of the calcium lactate. His condition then continued excellent.

Examination about the middle of April showed several small ecchymotic areas. There had been no bleeding from these, but thinking to prevent any future hemorrhage, they were cauterized with silver nitrate solution. In less than twenty-four hours severe epistaxis, lasting several hours, occurred from sloughing. Since then administration of calcium lactate has been continued twice a week and he has also been given iron with Fowler's solution. There has been no further hemorrhage.

Case 4.—J. C. K., aged 44, male, single, family history excellent.

History.—For twenty-one years the patient has been advance agent for a minstrel troupe and very active. He has always been in perfect health, except that two years ago he was treated for a mild attack of lumbago. The only indication of rheumatism has been slight pain and stiffness in the left shoulder at intervals, since last December. He first came under observation on Jan. 6, 1906.

This patient showed no purpuric tendency until the middle of June, 1905, when he noticed a purplish area several inches in diameter on the left thigh, followed a few days later by a similar area on the right thigh. About August 1 numerous small spots appeared on both legs and since then successive crops come and go, so that he has never been free from them. Walking is always followed by innumerable new eruptions. At times many spots have appeared on the limbs. The slightest bruise was invariably followed by an ecchymotic area.

While riding on a train, June 24, 1905, he had a sudden, profuse hemorrhage from the right nostril and fainted away. Between then and October 1 there were five very severe attacks of epistaxis, requiring packing of both nares. After one of these the patient was in a hospital for three weeks, merely from exhaustion, and he has not been able to work since early last autumn. There had been no profuse epistaxis since October 1, but frequent oozing from the nose. Numerous hemorrhagic areas have appeared on the gums and throughout the mouth. There has never been any blood in the urine or stools.

This patient was treated in several cities, both in hospitals and by physicians in private. He states that he was given calcium chlorid, the adrenal preparations, ergot, etc., and that the nose was treated locally with numerous styptics.

Examination.—When first seen, Jan. 6, 1906, there were multitudes of petechial and ecchymotic areas in all stages of development over both legs. There were a few small spots scattered over the trunk and large areas on the arms. The lips showed several spots, the gums were discolored in places and appeared soft.

Blood Examination: On January 6, blood examination showed red cells 4,928,000, white cells, 8,000, hemoglobin, 70 per cent. The differential count was normal and the plates practically absent.

Treatment and Result.—The patient was given sixty grains of calcium lactate at once and fifteen grains three times a day for a week. Two hours after the initial dose the coagulation time was lowered from six and one-quarter to five and one-quarter minutes. As this patient lived out of the city he was seen only once a week and later once in two weeks.

After the first week's treatment there was a marked improvement, the old spots fading, a few new ones appearing. The patient stated that he had noticed a change for the better in three or four days. From that time there has been a slow but steady improvement. For experimental purposes the calcium lactate was stopped on several occasions; such action was invariably followed by numerous petechiæ. At these times also the coagulation time was lengthened, only to be lowered by the lactate.

During the last two months this patient has taken regularly thirty grains of the lactate twice a week. He has led a very active life, often walking several miles a day over rough country and through bushes, and has also rowed a boat long distances. His condition is excellent and he seems a well man.

Blood examination recently showed the red cells to be 5,280,000, white cells, 9,000, and the hemoglobin, 90 per cent. A stained specimen was normal, except that the plates were still very low. The count of the plates was 25,023 to the cubic millimeter. This being so we do not consider this man cured, but believe the purpuric tendency is kept under control. The patient thinks himself as well as ever and is going to return to work soon.

Case 5.—H. H., male, aged 33, married.

History.—This man was very large and robust and had never had any sickness. For years he has been a steady drinker, taking three or four glasses of beer and one glass of whisky a day. He was first seen by Dr. L. L. Bradshaw, to whom I am indebted for the case, on April 8, 1906. Four months before, the patient had noticed a few reddish spots on the right ankle. These slowly extended upward to the knee and to the left leg. As there was no discomfort he did not consult a physician and continued at his work in a lumber yard. About two weeks before coming under observation he began to spit blood occasionally, from oozing of the gums, and this continued. On April 7 this was much more profuse, but he still worked all day. That evening eruption appeared over the entire body.

Examination.—When seen on April 8 there were petechial and ecchymotic areas, some larger than a palm, over the entire body, face and scalp. He was spitting blood several times a minute from the gums, and all of the mucous membranes of the mouth. Sixty grains of calcium lactate were at once given and thirty grains ordered three times a day. The next day, many of the areas had ruptured and were covered with crusts. The gums still bled freely.

Blood Examination: This showed red cells, 4,480,000, white cells, 12,000, hemoglobin, 90 per cent. The differential count was polynuclear leucocytes 79 per cent., lymphocytes, 12.3 per cent., large mononuclears, 4.3 per cent., transitional, 4 per cent., eosinophiles, 0.3 per cent. The plates were practically absent.

Urine: On the evening of this day the patient began to pass large amounts of blood in the urine. A specimen, centrifuged, showed 13 per cent. of sediment composed almost entirely of red cells. Large amounts of quite fresh blood also appeared in the stools.

Course of Disease.—The following day, April 10, there was much less blood from the mouth and the skin eruptions were fading. The urine showed 10 per cent. of blood. The anemia was increasing. The red cells showed marked variation in shape and size and a few normoblasts appeared. On April 11. the coagulation time, then taken for the first time, was eight minutes, and this was after large doses of the calcium lactate for several days. The urine showed 5 per cent. of blood. April 12, through a mistake of the nurse, sixty grains of the calcium lactate were given every three hours for six doses, but no ill effects followed. On the following day, the thirteenth, the urine was free from blood and all bleeding had ceased from the skin and mucous membranes. The red cells were now 3,168,000, white cells, 13,500, and the hemoglobin, 60 per cent. The coagulation time was six and three quarters minutes. The plates were still almost absent.

For several days during the bleeding period the temperature varied between 100 and 102 F. by mouth, and the pulse between 100 and 120. This, with the presence of a polynuclear increase, is an indication of an infection of some sort.

On April 14, Fowler's solution was begun in doses of four minims every four hours. On the next day the blood plates were fairly numerous, scattered throughout the specimen, but none occurring in clumps, as is normally seen. Many of them were large. The calcium lactate was continued, thirty grains three times a day, until April 17, when it was stopped. On April 21, the plates appeared normal in number and the improvement in the general condition was marked. The urine now showed a trace of albumin and a few hyaline casts, so the arsenic was discontinued. No further blood examination was made until April 27, when it was noted that the plates were again much reduced and a remark was made to the attending physician that more bleeding would probably occur.

On the evening of April 30 blood began to ooze from the gums. This gradually increased, reaching a maximum on May 3, when there was considerable bleeding from the gums and tongue, but not approaching in severity the original attack. There was no bleeding elsewhere. Only one dose of calcium lactate of 30 grains was given daily for the first three days, but on May 3 the dose was increased to 40 grains every three hours.

I did not see the patient until May 4, when the red cells were 4,120,000, white cells 7,000 and hemoglobin 70 per cent. The coagulation time was eight and three-quarters minutes. The plates were still nearly absent. The bleeding was much less on this day and ceased on May 5.

A blood specimen taken May 9 showed a few scattered plates. Administration of arsenic was started on this day. On May 10 the plates were much more numerous, many occurring in clumps. The next examination was on May 14, when they were perfectly normal in appearance. The calcium lactate was slowly decreased, first to 20 grains three times a day, then twice a day and to one dose daily. The improvement has been rapid and the patient is now out of doors.

This case was one of acute hemorrhagic purpura of the most severe type. The prognosis in a large proportion of these is extremely grave.

Sahli,[4] as late as 1905, made the statement that the value of calcium chlorid in hemophilia is still awaiting judgment.

In view of the cases here reported, it seems that the calcium, or probably the magnesium salts as well, offer the best hope of relief of any therapeutic measure so far advised.

We are, of course, aware that theoretically there is some danger of causing thrombi formation, but this must be slight if we determine with each case the minimum dose necessary to make the patient comfortable. Thirty or forty grains of calcium lactate once or twice a week is usually sufficient in the chronic cases. The large doses given to the patient with acute hemorrhagic purpura is evidence of the harmlessness of the drug when such doses are necessary.

The lactate is more easily absorbed by most patients than the chlorid of calcium and the taste is much more agreeable. The chlorid is nauseating to many individuals, while the lactate is a tasteless, chalk-like powder.

All the patients were also directed to drink from one to two quarts of milk a day, and some of the improvement probably results from this, for Wright and Knapp[5] have shown that this accelerates coagulation.

Summarizing the coagulation experiments in the above cases, it is seen that in two of the five it was decidedly above normal, in two others a high normal, and in the fifth a low normal. In all cases the blood must have had a high content of calcium, so the results attained are in accord with those of Wright and Knapp,[5] who demonstrated by chemical means, in 1902, that blood which contains a small amount of calcium is not always less coagulable, and also that blood containing much lime salts is not necessarily more coagulable than usual.

It has been claimed that the continued administration of calcium chlorid is not effectual in keeping up an increased coagulability of the blood, but, on the contrary, serves to lengthen the time. Consequently, its use has been confined to stopping acute hemorrhages or to prevent hemorrhage at an operation. Whether the effect of the lactate is different in this respect or the improvement is due, in the chronic cases, to the fact that the patients have taken the minimal effective dose I can not say, but concerning the improvement there can be no doubt. In no case has the coagulation time been lengthened by the lactate.

The patient in Case 1, the physician, and the patient in Case 3, the teacher of Latin, are educated men and keen observers. One of them has now been under treatment for five months, the other for four months. By regulating the calcium lactate carefully they can keep themselves infinitely more comfortable than for years.

In the course of these examinations many blood examinations were made. The one constant feature was the very small number of blood plates. Other observers have reported this, but, we believe, have not attached sufficient importance to it. Following such bloods from day to day one can not help thinking that there is a close relationship between the small number of the plates and the liability to bleed. In one of the cases, the plates suddenly disappearing, it was suggested, fully forty-eight hours before it began, that bleeding was about to recur. Blood from another patient (Case 2), taken the same day on which had occurred the most severe attack of epistaxis for months, showed a total absence of plates, whereas they had previously been present, but much below normal.

After the cessation of the bleeding arsenic was given with the idea of stimulating the hemogenetic organs. While the origin of the plates is still a much disputed point, the fact that they rapidly increased in number soon after beginning the arsenic in Case 5 would argue in favor of the bone marrow as their seat of origin.

During the last few years much has been written on the technic of counting the plates. Pratt's method of diluting the blood with a 2 per cent. solution of sodium metaphosphate and obtaining the ratio of the plates to the red cells is probably the best. While the actual enumeration is more accurate and especially valuable in reporting cases, the technic is arduous and can not be applied in many cases. Heretofore nearly all observers have agreed that little concerning the plates could be learned from a stained specimen. It must be remembered, however, that such investigations were made before the use of the azure dyes was common. We believe that by making evenly smeared, thin specimens and using a stain like Wright's, Leischmann's or the Nocht-Jenner of Hastings, which we have employed, fully as good an idea of the plates can be obtained as by counting them.

Secondary anemias, whether from hemorrhage, neoplasms or various other causes, always show a marked increase in the plates. In all the cases above reported there was at some time distinct anemia, but the plates were constantly reduced.

Another point of difference between the two varieties of anemia is that a leucocytosis is usual with secondary anemias, while it is uniformly absent with the anemia of purpura.

Keeping these points in mind, one should always be able to differentiate between a bleeding from a hemorrhagic diathesis and a hemorrhage from other causes.

New Appliance

A BED LIFT.

H. H. JANEWAY, M.D.
NEW BRUNSWICK, N. J.

The form of apparatus here described has proved itself so useful in the care of many of my postoperative cases, that it has seemed as though both those connected with larger hospitals as well as many who do most of their work with limited nursing help would welcome its use. There are many forms of bed lifts manufactured by the instrument makers, but all of these, so far as I have been able to discover, are so arranged that the patient must be lifted bodily on the machine, as a patient would be lifted on a stretcher, before it can be used.

DESCRIPTION.

In this form of apparatus, however, one nurse is easily able to place three bands beneath the patient, and thus alone to lift the patient. The one passed beneath the shoulders is readily placed by first lifting one shoulder and pulling the band down underneath the back until the upper border is on a level with the axilla, then the other shoulder is lifted and the band adjusted on this side of the body: the band passing under the hips is first pushed beneath the small of the back, and then first by lifting, or slightly rolling up one hip, and then the other, it is easily pulled down until its upper border is on a level with the anterior superior iliac spine. The other two bands are very quickly put in position, one beneath the calf of the leg, and the other attached to the same end-piece as the shoulder band, under the head (Fig. 1). The placing of all these straps is very rapidly done, being only a matter of a couple of minutes, and can all be accomplished by one person. The patient can now be lifted by one nurse and lies, when the bands are in their proper places, at perfect rest on them (Fig. 2.).

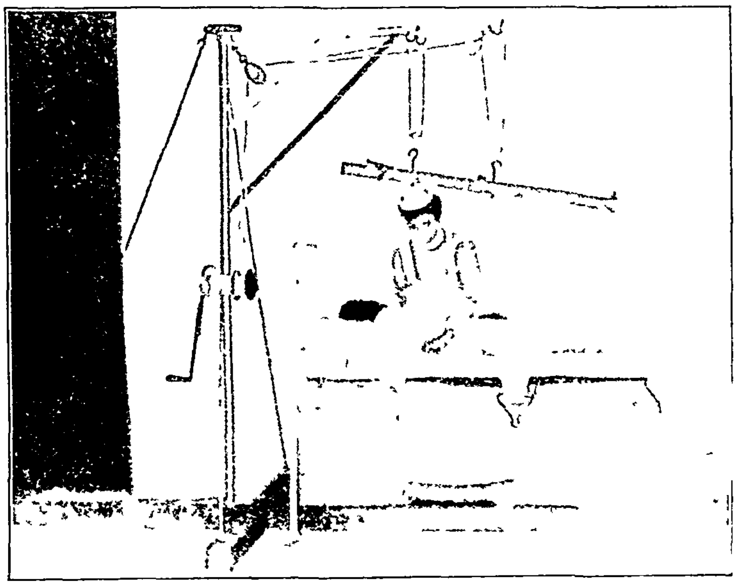

Figure 1

BENEFITS.

The nurse is then at liberty to change the bed, turn the mattress, introduce the douche pan, or thoroughly rub the patient's back. In cases of any tendency for the development of a bed-sore in a patient who has been obliged to remain for a long time on the back, instead of using one strap beneath the hips, which would rub on the sore, two straps with the bed-sore in the interval may be used, and thus the developing bed-sore readily dressed. In this case one strap passed beneath the small of the back and the other under the thigh just beneath the buttocks. It will thus be seen that any part of the patient's body can be made accessible. The patient is still at perfect rest when so lifted. This method of introducing the straps can also be used when, on account of excessive weight, it is more difficult to pull the hip strap down under the pelvis.

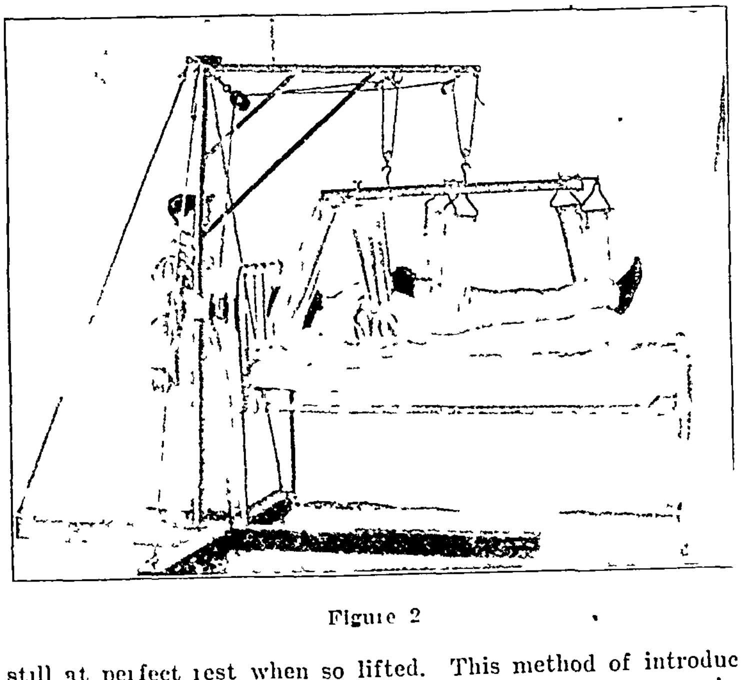

Figure 2

Aside from making nursing easier, the apparatus, in many cases, proves a veritable Godsend to the patient. The rest to the back after being lifted is very great. This is especially noticeable after operations, and is most useful for a long time after such operations as nephrorrhaphy, where it is undesirable for a patient to turn off from the back for some little time. Even after an ordinary laparotomy the possession of a way of lifting a patient off the back without strain contributes greatly to the taking of any tension off from the wound, such as might otherwise be due to excessive restlessness or too early turning. Of course, to that class of cases in which turning is very difficult, such as fracture cases and chronic illnesses, the machine proves a real blessing throughout the entire sickness.

Lately I have used the machine in cases of typhoid fever at the home of the patient with most gratifying results. By swinging the crane out to the side of the bed one nurse is able to give a regular bath without strain to herself or exertion to the patient (Fig. 3). Where the means of the family are limited so that only one nurse can be engaged, this form of bed lift has really meant to the patient the difference of having the bath treatment or going without it. Each nurse who has thus far become accustomed to the use of the lift has expressed herself enthusiastically over it.

The simplicity of the machine enables it to be manufactured at comparatively slight cost, Charles E. Dressler, 143 East Twenty-third street, having reproduced the one here presented at a most reasonable figure.

In one family in which the expense of a nurse was out of the question, and in which the mother lay for several months dying from secondary carcinoma of the liver, being absolutely bed-ridden, and before death weighing over 200 pounds, this apparatus enabled the two daughters to care for their mother, to make her comfortable, and to keep her back and bed in good condition until she died.

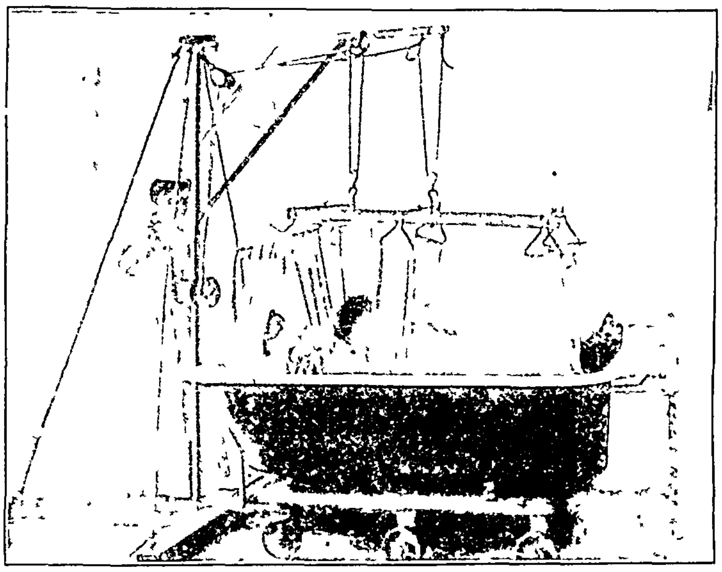

Figure 3

Clinical Note

CONGENITAL DISLOCATION OF THE HIP.

REDUCTION AT AN EARLY AGE.[†]

PRESCOTT LE BRETON, M.D.
BUFFALO, N. Y.

In cases of congenital dislocation of the hip diagnosis is possible soon after the child begins to walk, because the limp in unilateral cases or the waddle and lordosis in bilateral cases call attention to the condition.

In a certain number of cases, which are, nevertheless, congenital, dislocation does not occur until a later time. The period depends on the amount of deformity present.

---

[*] Read at a meeting of the Eighth District Branch of the Medical Society of the State of New York, Aug 17, 1906

This fact was well illustrated in the case of a child under my observation. When 2 years old she had a waddling gait and slightly increased lordosis, but not one symptom of dislocation could be discovered. Three months later the waddle and lordosis had increased and all the typical signs of a double dislocation were present. Complete luxation occurred between the examinations.

There is considerable difference of opinion as to the time that treatment should be begun in these early cases. Some orthopedists, notably Lorenz, prefer to wait until the third year, when diapers can be dispensed with. Others argue that it is best to reduce at once, in spite of the inconvenience in trying to keep the child clean. Their reasons for doing this are that it is much easier to reduce the dislocation at this time, complications are less likely, the period of treatment is short and the outcome more favorable because time has not allowed further changes to develop in the joint and neighboring soft parts. In regard to this matter Lorenz[1] says:

> Before beginning treatment, I wait not merely till the discrepancy in the gait declares itself beyond any question, but till the child is able to keep itself clean. Then, for reasons which are easily deduced, the treatment is so much simplified that I am accustomed to wait till the expiration of the second year before attempting reduction. It pleases me most if the children come to me for treatment after the expiration of the third year. By this time the unclean accompaniments following reduction are done away with; and on the other hand there is the important advantage that the greater tone of the soft parts materially enhances the stability of the primary position after the reposition is brought about, and so increases the chances for permanent reduction.

Ridlon[2] believes that those who have operated on cases under 2 years appreciate that, while it was perhaps more easy to return the head to the acetabulum than in the older cases, it was more difficult to keep it there. Wilson[3] thinks that, while it might appear on the surface that the earlier replacement is made the better it would stay, the fact exists that if the child is unable to walk a very important factor in the result is lost.

On the other hand we have the following opinions. Hoffa[4] says:

> In my opinion, the earlier children with congenital dislocation of the hip are subjected to treatment, the better will be the results.

Heusner[5] thinks that early infancy, with its energetic growth, offers the best prospects for regeneration, while delay invites rapid aggravation of the deformity.

Freiberg[6] says:

> The earliest possible replacement must be considered an important desideratum. The results amply justify the great additional care which is necessary to prevent the dressings from becoming soiled.

He reports the case of a child of 17 months of age, in which he obtained a good result. Bartow[7] reports three similar early cases, with good results. He also modifies the plaster cast in such a way as to prevent soiling. Hoffa covers the plaster cast with a solution of rubber to make it impervious to moisture.

The following case may be added to others in which treatment was instituted early:

C. S. P., male, aged 20 months, was referred by Dr. Dean, Mayville, N. Y., August, 1905. Family history, negative.

Personal History.—A first child. Labor had been prolonged for twenty-four hours, but neither force nor instruments had been employed. Baby was always in good health. For the previous two months, since he began to walk, a limp was noticed. This was so marked that it was really a lunge forward and downward on the right leg at every step. The child, however, made no complaint, but played and ran about freely.

Examination.—All the signs of a typical unilateral dislocation were found. The right leg was three-quarters of an inch shorter than the left. The trochanter was above Nelaton's line. On placing the finger on the upper edge of the trochanter and the thumb on the anterior spinous process, and then applying intermittent traction to the leg, the trochanter very plainly slid up and down under the finger, showing a lack of firm apposition between the femur and the pelvis. The right thigh was half an inch less in circumference than the left. The gluteal muscles of the right side showed a slight atrophy. There was no spasm. Motions were very free except abduction, which was slightly limited. On rotation, the trochanter did not move in the arc of a circle. On flexing and adducting the thigh, the head of the femur could be felt under the gluteal muscles. An *x*-ray picture, taken by Dr. W. W. Plummer, showed the elevation of the trochanter on the right side. It also seemed to show anteversion of the femoral neck.

Operation.—On Aug. 29, 1905, reduction was accomplished under chloroform anesthesia by the Lorenz method. The replacement was not difficult. The apposition was firm, and it was necessary to bring the thigh down from the Lorenz position to full extension before redislocation occurred, when the bone would jump suddenly back on the dorsum of the ilium. When reduced, there was the usual shortening of the hamstrings. The plaster spica was protected by rubber dam and the mother was instructed in detail about the care of the skin. A high shoe allowed free walking.

Postoperative History.—The child was sent home, returning in November, when the hip was examined and found in good condition. Dislocation did not occur even when the thigh was brought down parallel to the opposite one. In this extended position the legs were of equal length, and the firmness of the reposition argued well for the future. A new cast was applied with flexion reduced to 45 degrees, and with lessened abduction. On Feb. 3, 1906, a similar state was found, and the flexion was further reduced. On March 24, there was found for the first time a distinct fulness in front of the acetabulum near the anterior inferior spine, which disappeared during thigh flexion. The inference was plain that, owing to the deformed neck of the femur, the result would be an anterior transposition. A removable spica was made for night use, to hold the thigh during sleep in the primary position. This was continued for six weeks. A half-inch raise in the left shoe continued a slight abduction of the right leg.

Examination on July 2 showed a functional cure. The fulness could be felt, as before, in front of the acetabulum. The legs were of equal length and circumference. No limp and no increase of lordosis. The child appeared normal, and had had perfect freedom from restraint for over two months.

REMARKS.

It would seem that in this case, at least, a wait for a period of a year or over would have been a mistake. The mother did not complain of the extra trouble involved in caring for the child, and she was successful, inasmuch as no cast had to be changed because of soiling. The baby grew rapidly during its confinement, playing contentedly every day. The result obtained is the same as in the majority of cases, i. e., a functional cure by anterior transposition. Permanent replacement of the head in the acetabulum is obtained in a small minority of cases only. The frequency of this forward position of the head of the femur is supposed to be due to the anteverted neck and the shortening of the pelvi-trochanteric muscles, which latter is caused by the primary position of Lorenz. As the leg is finally brought to full extension these two factors throw the head forward out of the acetabulum.

New and Non-Official Remedies

The following articles have been tentatively accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in the proposed annual, "New and Non-official Remedies." Their acceptance has been based largely on evidence supplied by the manufacturer or his agent, but to some extent on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before final acceptance and publication in book form.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known it complies with the rules adopted by the Council.

W. A. PUCKNER, Secretary.

(*Continued from page 1021.*)

CREOSOTAL.

CREOSOTE CARBONATE.

Creosotal is a mixture of carbonic acid esters, analogous to guaiacol carbonate, prepared from creosote.

It is prepared by passing a current of carbonyl chloride into a solution of creosote in sodium hydroxide, and purifying the oily product by washing with weak soda solution and with water.

It is a yellowish, thick, honey-like, perfectly clear and transparent liquid, containing 92 per cent of creosote. It is odorless and has a bland oily taste. It is insoluble in water, but soluble in alcohol, ether, chloroform, benzene and in fixed oils

The addition of a few drops of ferric chloride solution to the alcoholic solution should not cause any change in color. On boiling with potassium hydroxide solution the odor of creosote is evolved.

It is incompatible with boiling alkalies.

Actions and Uses.—Creosotal has the same action as creosote, but is claimed to be non-toxic and devoid of irritant properties. It is recommended as a substitute for creosote for internal exhibition in tuberculosis, pneumonia, and as an intestinal antiseptic.

Dosage.—From 0.3 to 2.0 Gm. (5 to 30 grains) for children, to 1 to 4 Gm. (15 to 60 grains) for adults in milk, coffee, wine, cod-liver oil or emulsion. Externally it may be applied undiluted.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). Fabrik von Heyden, Radebeul, near Dresden German patent No. 58,129; U. S. patent No 501,235; U. S trademark.

DENTALONE.

A saturated solution of chloretone (which see) in a liquid composed of oil of cloves, oil of gaultheria and oil of cassia, and containing 30 per cent of chloretone.

It is a reddish-brown oily liquid of characteristic odor and taste.

Actions and Uses.—Dentalone possesses pronounced anesthetic properties and is intended for use by dentists in the treatment of exposed nerves in decayed teeth.

Prepared by Parke, Davis & Co., Detroit, Mich. U. S. trademark

DERMATOL.

A name applied to Bismuthi Subgallas, U. S. P.

Manufactured by Meister, Lucius & Bruening, Hoechst a. M (Victor Koechl & Co, New York).

DIABETIN.

LEVULOSE. FRUIT SUGAR. FRUCTOSE.

Diabetin is a pure, crystallized fructose (levulose), $CH_2OH\ CHOH.CHOH.CHOH.CO.CH_2OH = C_6H_{12}O_6$, absolutely free from dextrose (ordinary glucose).

It is prepared from invert sugar by precipitation as calcium salt, decomposing the precipitate with carbonic acid and crystallizing It is a colorless odorless, slightly hygroscopic crystalline powder, having a sweet taste comparable with that of ordinary cane sugar (saccharose). It is readily soluble in water and in diluted alcohol slightly soluble in alcohol, insoluble in absolute alcohol and in ether

Its aqueous solution reduces Fehling's solution and rotates the ray of polarized light to the left (—90 2)

Actions and Uses.—Levulose is metabolized in the body by other agencies than those that act on dextrose and most of the other sugars and appears to be more completely utilized by the diabetic organism than the other sugars.

It is recommended for the nutrition and for sweetening the food and drink of diabetics, in pulmonary tuberculosis, infantile malnutrition and marasmus.

Dosage.—It is given in diabetes in daily quantities of 30 to 60 Gm. (1 to 2 ounces); in grave forms of the disease the amount is reduced to from 12 to 24 Gm. (3 to 6 drams) daily.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering. Berlin (Schering & Glatz, New York). U. S. trade-mark No 21,864.

DIONIN.

ETHYL-MORPHINE HYDROCHLORIDE. CODETHYLINE HYDROCHLORIDE.

Dionin, $C_{17}H_{17}NO(OH)(OC_2H_5)HCl + H_2O = (C_{19}H_{24}O_3ClN + H_2O,)$ is the hydrochloride of the ethyl ester of morphine.

It is prepared by the action of ethyl iodide on morphine in the presence of alkali, the basic product being purified by crystallization from hot alcohol, dissolving the crystals in hydrochloric acid and crystallizing

It is a white, microscopically crystalline powder, odorless and only slightly bitter It is soluble in about 7 parts of water and in 2 parts of alcohol, insoluble in ether and in chloroform. It melts completely with decomposition at 125° C. (257° F.).

It gives the usual reactions for alkaloids It is distinguished from morphine salts by its insolubility in excess of alkali, and by not producing an immediate blue color, but gradually developing a blue green coloration, when its solution is added to dilute ferric chloride solution containing a fragment of potassium ferricyanide

It is incompatible with alkalies and their carbonates and alkaloidal reagents, as potassio-mercuric iodide, tannic acid picric acid, etc.

Actions and Uses.—It is claimed that this compound acts like morphine without producing constipation, nausea or lassitude. It is the conclusion of some good observers that it possesses no advantage over codeine. Applied to the eye, it causes a local vaso-dilation, leading to acute conjunctival edema.

Dionin is recommended to relieve pain, especially in respiratory affections, as an antispasmodic in whooping-cough, for insomnia and externally in the treatment of corneal affections, conjunctivitis, iritis, etc.

Dosage.—0.015 to 0.06 Gm. (¼ to 1 grain). Externally it is applied in 10 to 20 per cent. solutions.

Manufactured by E Merck, Darmstadt. (Merck & Co., New York) German patents Nos 102,654, 107,225, and 108,075. U S trademark.

DIURETIN.

A name applied to theobromine-sodium salicylate. which see.

Manufactured by Knoll & Co, Ludwigshafen, Germany (E Merck & Co, New York).

DUOTAL.

A name applied to Guaiacolis Carbonas, U. S. P.

Manufactured by Farbenfabriken, vorm Friedr. Bayer & Co Elberfeld, Germany (Continental Color & Chemical Co, New York) U. S. patent No. 466,913 U. S. trademark.

DUOTONOL.

A name applied to a mixture of equal parts of calcium tonol and sodium tonol. (See tonols)

Actions and Uses and Dosage.—See Glycerophosphates.

Manufactured by Chemische Fabrik auf Actien vorm E. Schering, Berlin (Schering & Glatz, New York). U. S trademark.

ELIXIR EUPNEIN.

COMPOUND ELIXIR OF HEROIN, CREOSOTE AND TERPIN HYDRATE, SCHIEFFELIN.

A preparation said to contain in each dose of 8 Cc. (2 fluidrams): heroin 0 0026 Gm. (1/24 grain), terpin hydrate 0 13 Gm (2 grains), creosote 0 3 Gm (5 grains), in a menstruum containing 30 per cent. of alcohol with glycerin and aromatic essential oils.

Actions and Uses.—From its composition it appears to be well adapted to use in chronic cough from bronchitis, etc.

Dosage.—4 to 12 Cc. (1 to 3 fluidrams).

Prepared by Schieffelin & Co., New York. U. S. trademark No. 36,419.

ELIXIR SAW PALMETTO.

ELIXIR SABALI, SANTALI, ET ZEÆ MAIDIS.

A preparation said to represent in each 30 Cc. (fluidounce): Saw palmetto berries 8 Gm. (120 grains): sandalwood 2 Gm. (30 grains: : and cornsilk 8 Gm. (120 grains).

It is stated to contain 36.7 per cent. of alcohol.

Actions and Uses.—The constituents of this preparation are credited with diuretic properties and believed to be sedative to the genitourinary tract and to exert a curative action on the inflamed mucous membrane, especially in chronic cases.

Dosage—4 to 16 Cc. (1 to 4 fluidrams) three times a day.

Prepared by Parke, Davis & Co., Detroit, Mich.

EMPYROFORM.

Empyroform is a condensation product of birch tar and formaldehyde.

According to the patent specifications birch tar is boiled with formaldehyde solution and the hot liquid poured into hydrochloric acid. When cold, the solid mass is collected and washed until free from acid.

It is a grayish-brown, almost odorless powder, insoluble in water, but readily soluble in solutions of caustic alkalies, in acetone, and in chloroform.

Actions and Uses.—Empyroform is an antipruritic, sedative and desiccant. It is said to be superior to tar and free from irritant or toxic effects.

It is claimed to be useful in all stages of eczema, psoriasis, lichen, urticaria, prurigo, pityriasis, etc.

Dosage.—It is applied as a 5 to 10 per cent. ointment, 10 to 20 per cent. zinc paste, 10 to 20 per cent. tincture, and 37.5 per cent. suspension.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin (Schering & Glatz, New York). U. S. patent No. 761,260. U. S. trademark No. 43,419.

EPICARIN.

OXYNAPHTHYL-ORTHO-OXYTOLUIC ACID.

Epicarin, $C_6H_3(OH)(COOH)(CH_2C_{10}H_6OH)2:3:1 = C_{18}H_{14}O_4$, is β-naphthol-hydroxy-toluic acid.

It is obtained by the action of chlormethyl-salicylic acid on a solution of b-naphthol, in glacial acetic acid, thus:

$$C_6H_3(OH)(COOH)(CH_2Cl) + C_{10}H_7OH = C_6H_3(OH)(COOH)(CH_2C_{10}H_6OH)+HCl$$

It forms colorless or yellowish needles, melting at 190° to 195° C. (380° to 389° F.), difficultly soluble in water, but easily soluble in alcohol, ether, acetone, and in soaps. It dissolves in oils on the addition of a little ether. It has the character of a strong acid, forming well crystallized salts, which, however, are sparingly soluble in water, particularly the sodium salt. On exposure to air it acquires a reddish color due to oxidation; if it is then recrystallized from glacial acetic acid, colorless crystals are again obtained which melt at 166° C. (338° F.). These, however, retain a little acetic acid, but lose this by heating at 120° C. (248° F.).

The alcoholic solution of epicarin produces an intense blue color with ferric chloride. When heated with concentrated sulphuric acid, a red-brown solution, having a vivid green fluorescence, is produced. If shaken with chloroform and solution of potassium hydroxide, a yellowish color, changing later to yellowish green is developed, thus distinguishing epicarin from b-naphthol, which produces a deep blue color under the same conditions.

Being a strong acid it is incompatible with alkaline hydroxides or carbonates, especially those of sodium with which it forms an almost insoluble salt. It should not be exposed to the air, which colors it red.

Actions and Uses.—Epicarin is a non-poisonous antiseptic and parasiticide. Administered internally, it is excreted mostly undecomposed. It has been found useful in the treatment of skin diseases, particularly scabies, tinea tonsurans, prurigo and certain forms of eczema.

Dosage.—It is used externally only in the form of 5 to 20 per cent. ointment, with petrolatum or wool fat (lanolin) as base, or in the form of oily or alcoholic solutions (10 per cent.).

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York). U. S. patent applied for.

ERYTHROL TETRANITRATE.

ERYTHROL NITRATE. TETRANITROL.

Erythrol tetranitrate, $C_4H_6(NO_3)_4=C_4H_6O_{12}N_4$, is the tetranitrate of erythrite or butane-tetrol, $C_4H_6(OH)_4$.

It is obtained by the nitration of the tetratomic alcohol erythrite.

It forms colorless crystalline scales, insoluble in cold water, readily soluble in alcohol, melting at 61° C. (141.8° F.). On percussion it explodes much like nitroglycerin.

Actions and Uses.—It is a vasodilator and antispasmodic, like nitroglycerin. Its action is slower and more lasting; it begins in 15 minutes and persists for three or four hours.

It is recommended in angina pectoris and cardiac diseases. It is reported as especially useful as a prophylactic in preventing anginal pain.

Dosage.—Because of its explosiveness it is marketed in the form of tablets, each containing 0.03 Gm. (½ grain). One or two tablets every four to six hours.

Manufactured by E. Merck, Darmstadt (Merck & Co., New York). German patent No. 81,664.

ETHYLENEDIAMINE.

AETHYLENDIAMIN. AETHYLENE DIAMINE. ETHANE DIAMINE. *a,b*-DIAMINO-ETHANE.

Ethylenediamine, $C_2H_4(NH_2)_2$, is a substitution compound of ethylene and ammonia.

It is prepared by heating ethylene bromide with an excess of alcoholic ammonia for 12 hours at 100° C. (212° F.), removing the ammonium bromide formed, by filtration, evaporating the filtrate to dryness, distilling the residue with potassium hydroxide, and collecting the fraction distilling between 115° and 130° C. (239° to 266° F.) and bringing the liquid by successive purifications to a constant boiling point at 117° C. (242.6° F.).

It is a clear, colorless, thick liquid, having a sp. gr. 0.97, boiling at 117° C. (242.6° F.), without decomposition, having a strong alkaline reaction, an ammoniacal odor and a caustic taste. It is freely soluble in water, and may be mixed with cresols, but is not miscible with benzene (benzol) or ether. It dissolves albumin very readily, even when boiled.

Being a strong base its incompatibilities are about the same as those of sodium hydroxide.

Actions and Uses.—It is said to be non-corrosive. It is recommended as an albumin solvent for the solution of false membranes in diphtheria and similar affections of the mucous membranes. It is recommended for use in the form of kresamine (which see).

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin (Schering & Glatz, New York).

EUCAINE.

The "Eucaines" are two closely allied synthetic bases, which were originally differentiated as eucaine "A" and eucaine "B," but are now designated as "Alpha-eucaine" and "Beta-eucaine" respectively, alpha-eucaine being a synthetic derivative of triacetonamine, while beta-eucaine is a synthetic derivative of vinyl-diacetonekalmine. Both of these bases are supplied as hydrochlorides and are recommended as substitutes for cocaine, over which they are claimed to have certain advantages.

They are described under alpha-eucaine hydrochloride and beta-eucaine hydrochloride.

EUCALOIDS.

A name applied to gelatine capsules, each containing 0.3 Cc. (5 minims) of pure oil of eucalyptus.

Dosage.—1 to 2 globules three or four times a day.

Prepared by Edward G. Binz, Los Angeles, Cal.

(To be continued.)

Travel Notes

DISEASES AND HOSPITALS OF AFRICA

NICHOLAS SENN, M.D.
Professor of Surgery in the University of Chicago; Professor and Head of the Surgical Department, Rush Medical College.
CHICAGO.

(*Continued from page 1051.*)

THE HOSPITALS OF PRETORIA AND CAPE TOWN.

Pretoria, the former proud capital of the republic of South Africa, is only two hours distant from Johannesburg by rail. There is nothing to be seen here which would remind one of the terrible struggle which the brave Boers made in defending their rights and in maintaining their independence. Their leader, the late President Kruger, sleeps now in the little cemetery, surrounded by members of his family, who preceded him in death, and blue violets are blooming on his grave, symbolic of the purity of his private and public life. The city remains the same as before the war, but the magnificent public buildings, built and paid for by the Boers, are now in possession of the new administration. The Boers, a law-abiding people, have accepted their defeat in humility. Their worldy losses will be repaired in course of time, but the wounds inflicted by the cruel war will never heal under the present methods of foreign administration.

The city has about 25,000 inhabitants and is beautifully situated in a valley, surrounded by picturesque mountain scenery. It is an ideal capital city without the noise, smoke, and disturbances of manufacturing establishments. It has wide well-paved streets, many beautiful residences, very interesting botanic and zoologic gardens combined, good public schools, fine churches and a most excellent little hospital.

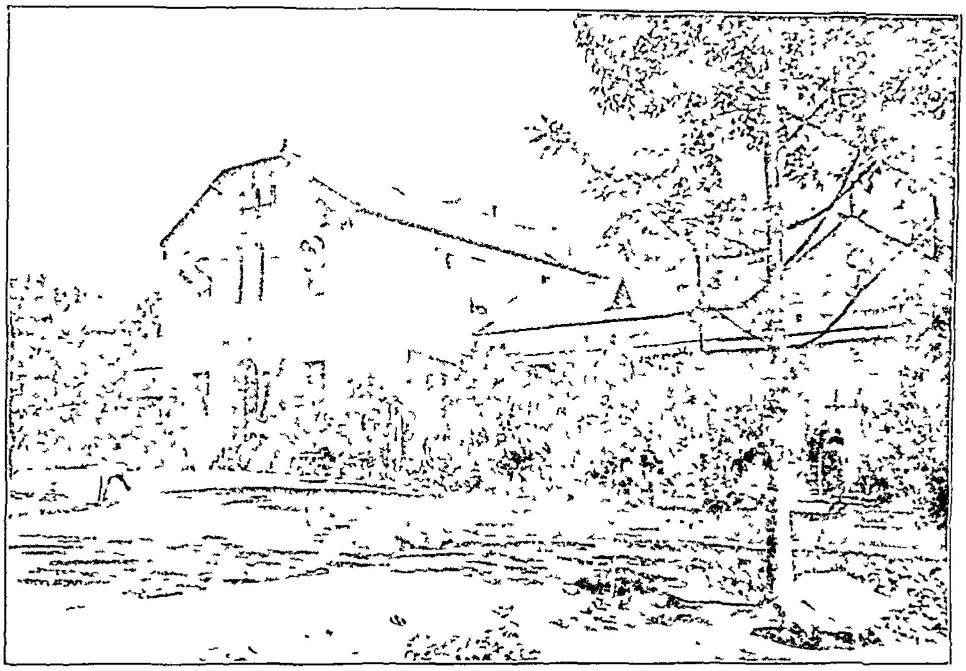

Fig. 1.—Pretoria Hospital.

THE PRETORIA HOSPITAL.

This hospital was completed, as indicated by an inscription on the corner-stone laid by President S. J. P. Kruger, June 21, 1890. The hospital, built of brick on the pavilion plan, has accommodations for 170 Europeans and 80 natives (Fig. 1.). It is charmingly located in a quiet outlying part of the city on an eminence and in the midst of large grounds, tastefully laid out and ornamented with evergreen trees, shrubs and a profusion of flowers. The general wards are airy, well-lighted and everywhere the most scrupulous cleanliness prevails. The snow-white linen, the cheery fires in open grates, the happy contented faces of the patients, white and black, old and young, suggest that the management of the institution is in competent hands (Fig. 3.). The nursing is in charge of five English sisters, assisted by 45 pupil nurses, who remain in training three years before they are permitted to apply for the final examinations. The corridors and walls are paved with large squares of artificial stone admirably adapted for this purpose. Dr. G. Thornton, the medical superintendent, lives in a comfortable, well-appointed house in the same grounds. The nurses' home, recently completed, is what such an institution should be, a real home for the nurses with all the comforts of a home. Dr. Thornton and his wife, formerly a trained nurse, devote their whole time and attention to the best interests of the institution and the comfort and well-being of its inmates. Dr. Thornton is a careful, conscientious practitioner and thoroughly devoted to his patients, regardless of their color. The natives in this hospital receive more consideration and care than in any other hospital visited. In the female wards for natives, I saw a patient about 35 years old, the subject of advanced carcinoma of the uterus. The woman was a half caste. Recently a case of molluscum fibrosum was observed in the hospital and through the courtesy of Dr. Thornton I make use of a photograph which he took himself (Fig. 2.).

Oil of cinnamon in three-drop doses, in emulsion, is the routine medication in typhoid fever. The mortality of this disease in the hospital does not exceed ten per cent., certainly an enviable record. In 3 out of 24 cases of perforation of the bowel in typhoid cases, life was saved by operative interference. Pneumonia here, as in all other hospitals in Central South Africa, is one of the most frequent and fatal of all diseases. The mortality ranges between 10 and 40 per cent.

From the report of the hospital for 1904-1905, I have gleaned a number of important facts. The operating theater is not what it should be, and a recommendation to rebuild it is one of the first items in the report. The *x*-ray apparatus and room are in good working condition, as shown by a number of specimen illustrations exhibited by Dr. Thornton. Reference to venereal diseases is made as follows: "Our experience shows that venereal diseases, both among the males and females, are becoming increasingly prevalent in the natives, thereby constituting a grave danger to public health, seeing that so many are employed in domestic service." Few sufferers of this class of disease are actually admitted into the hospital, but many are treated as "out-patients." The whole number of patients in this hospital during the year was 1,697, of whom 929 were Europeans and 768 natives. Only fifty-two cases of malaria came under treatment, and all the patients recovered. Of 140 patients with pneumonia, 33 died, and of the total cases, 97 were natives, with 28 deaths. Twenty-four natives suffering from tuberculosis of the lungs were admitted and 11 of these died. Of 33 cases of scurvy occurring, the disease proved fatal in one. Four cases of leprosy and one of filariasis, all in natives, were observed during the year. Among the native patients the diagnosis of malignant tumor appears 6 times and of benign tumor, strangely, only once. Concerning the malignant tumors, no distinction is made between sarcoma and carcinoma.

The farther south I travel and the more the natives are bleached out by the admixture of European blood, the more I find them receptive to the diseases of the whites, and this applies with special force to appendicitis and malignant disease. My observations in different parts of the world have convinced me that the nearer the human race approaches the animals in eating and habits of life the more they are exempt from malignant disease and appendicitis.

Two cases of appendicitis occurring in natives are recorded in the report, of which one proved fatal. Of 5 cases of gunshot wounds occurring in natives, all recovered. Dr. A. W. Sanders is the visiting surgeon and exercises a general supervision over the treatment of surgical cases and performs most of the major operations. During the year, 361 operations were performed, covering nearly the entire field of surgery, and of these 20 patients died. The greatest mortality was in cases of abscess of the liver, 6 cases with 4 deaths and operations for malignant tumors, 7 cases with 2 deaths.

TRANSVAAL LEPER SETTLEMENT.

Five miles from Pretoria in a valley surrounded by hills is the Transvaal Leper Settlement, founded by the Boers long before the war and now administered by the new government. It is a large village made up of comfortable little houses in separate groups for males and females, whites and blacks. The administration building, in which reside the superintendent and physician and supervising trained nurse, and in which the pharmacy and offices are located, are modern, substantial structures. The number of lepers who reside here now is 330, of which 280 are natives and 50 whites, most of the latter are Boers of the lower classes. The village is laid out in streets and includes a neat little Dutch Reformed church, school house and a building for public amusements. Small vegetable and flower gardens contribute much to mitigate the picture of human woe and suffering seen on all sides. Segregation is aimed at but not strictly enforced. Friends and visitors are admitted on stated days and by obtaining permission the lepers can leave the enclosure but must return the same evening. The settlement is under government control and all expenses are paid out of the public fund. Patients are paid a small sum for their work, if they choose to employ a part of their time in that way. This is an excellent thing, as useful employment chases away melancholy and with the little money earned the patients can buy for themselves such things as will make them more comfortable and happy. All the patients were decently dressed, their surroundings were clean and their general appearance indicated that they are well cared for and make the best of their misfortune. I saw here many cases in which the disease had produced frightful ravages, both in the tubercular and in the anesthetic forms. The treatment pursued is entirely symptomatic, no vaunted specifics are tried. Miss A. M. Whiteman, an English trained nurse, is the ministering angel in this valley of human suffering and misery. The patients respect and adore her and she is devoted to them. She speaks Dutch and all the native tongues and all come to her when they are in trouble, or in need of her services, which she so cheerfully and willingly renders them.

Fig 2.—A native patient in Pretoria Hospital with fibroma molluscum

"For man to assist man is to be a God.
This is the path to eternal glory."

Plinius Major.

CAPE TOWN.

Cape Town is the metropolis of South Africa and the capital of Cape Colony. It is situated at the base of Table Mountain on the south-west shore of Table Bay. It was founded by the Dutch in 1562, and ceded to Great Britain in 1815. The location of the city is picturesque in the highest degree. It faces the broad Table Bay and behind it are the almost perpendicular huge gray granite walls of Table Mountain. The city was laid out by its Dutch founders with mathematical precision, all its principal streets running in straight lines from the mountain to the sea and being crossed again by the other less important ones at right angles. It is the easiest city of its size for the stranger to find his way without a guide; he can not possibly get lost as the city occupies the narrow but long belt of land hemmed in on one side by the mountains and on the other side by the bay. Its length, with the many suburbs, must be at least ten miles, while its width does not exceed anywhere three-quarters of a mile. The main streets and sidewalks are wide and well paved and kept in good repair and thoroughly clean. The perfect system of sewerage, the abundant supply of pure water from the mountains and the superb climate make it one of the healthiest cities in the world. It is lighted by electricity and the two-story electric tramway cars promote easy transportation to all parts of the city and suburbs.

The principal business street is Adderly street, which is to Cape Town what State street is to Chicago or Broadway to New York. At the business end of this street a broad street-like walk lined on both sides with venerable oak trees leads to the base of the mountain. On the right side of the magnificent walk are the Botanical Gardens and South African Museum. In these gardens will be found nearly all the principal trees and shrubs indigenous to Africa, all labeled in botanical terms. It is a pity that the common names by which the people know the trees and shrubs are not given in the legends. The museum contains a fine collection of wild animals of Africa, well mounted and kept in excellent condition. The collections of minerals, birds and insects are very large and well arranged. The oldest landmark in the city is the castle, an old-fashioned fortress on the very edge of the bay, built by the Boers in 1660; in its almost medieval Dutch architecture, it forms a curious sight among the modern surroundings.

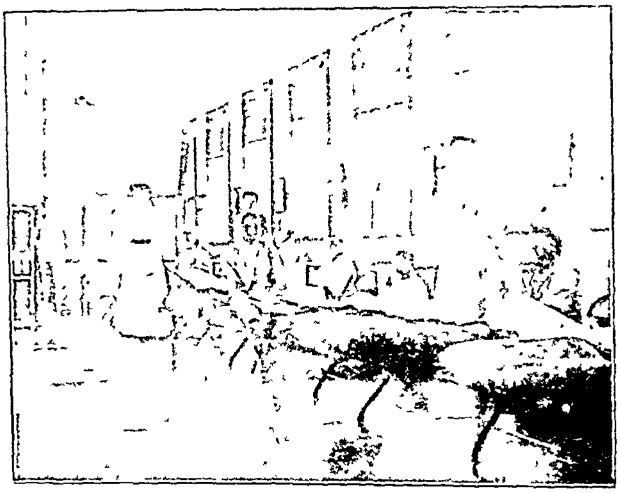

Fig. 3.—Native ward in Pretoria Hospital.

Table mountain furnishes the botanist with the greatest variety of interesting and rare specimens of plant life. Cape Colony has the largest variety of flowering plants to be found in any country, some 7,000 having been classified. On Table mountain and its slopes and ravines, 400 different varieties of heather have been found and analyzed. This small shrub has a profusion of small tubular flowers in vivid colors, red, yellow and white. These flowers are sold in large bunches on the street for a shilling each. The most interesting tree on Table mountain is the silver tree (*Leucadendron argenteum*) with its long narrow, willow-like shining silvery leaves arranged in dense imbricated clusters at the very end of the thick, abruptly ending twigs. The fruit is a cone the size of a duck egg.

SATURDAY, OCTOBER 6, 1906.

THE INTESTINAL ORIGIN OF PULMONARY TUBERCULOSIS.

It is the general belief that pulmonary tuberculosis in the overwhelming majority of cases is the result of inhalation of tubercle bacilli. This seems such a natural and easy way to account for tuberculosis of the lungs. This explanation is supported by numerous experiments on animals in which forced inspiration of bacilli appeared to be followed by direct localization of bacilli in the lungs. The inhalation theory is also in harmony with the well-known fact that living bacilli occur in the dust and in droplets of sputum about tuberculous patients that use little or no care to prevent contamination of their surroundings; and with the further fact that commonly there is no lesion discoverable elsewhere in the body to which one can trace the pulmonary disease.

Nevertheless important objections are being urged against the inhalation theory of pulmonary tuberculosis, especially in its extreme form, which tends to minimize the dangers of the alimentary route of infection. Behring's contention that the milk of tuberculous cows is the most important source of tuberculosis is so well known that details need not be discussed. The recent anatomic studies by Harbitz[1] of the distribution of tuberculous lesions, especially in children, afford many points in support of the view that tuberculosis of the lungs and adjacent lymph nodes may result from invasion through the digestive tract. It is not feasible to bring forward in detail all the facts and interpretations bearing on this question. Suffice it to state that until recently there existed no really satisfactory evidence of an experimental nature showing that tubercle bacilli introduced in the digestive tract actually are primarily or rapidly localized in the lungs and thoracic lymph nodes. The experiments of Calmette and Guérin[2] of Lille appear to furnish important information in regard to this phase of the question. These investigators find that in cattle and goats the introduction of a single quantity of virulent bacilli by means of the esophageal tube, particular care being taken to avoid contamination of the respiratory tract, is followed regularly in from 30 to 45 days by the development of subpleural and peribronchiolar tubercles at the tops and anterior borders of the lungs. Later the alveoli may be invaded from extension of the lesions which primarily are intracapillary. As others have shown before, the bacilli can pass through the walls of the stomach and intestines without leaving any lesions; on reaching the chyle vessels the bacilli are taken up by leucocytes and conveyed to the regional lymph nodes, whence they may escape into the thoracic duct without necessarily causing lesions until they reach the capillaries of the lungs and the thoracic lymph nodes as well as, but more rarely, elsewhere. As localization occurs, Calmette and Guérin believe that the leucocytes which carry the bacilli become immobilized by toxic bacillary products. They also point out that previous experiments which appeared to demonstrate tuberculous invasion by the respiratory tract are open to the objection that the bacilli introduced in reality were absorbed by the digestive tract.

Assuming that the experimental results here outlined in great brevity are applicable to human beings, it necessarily follows that particular care must be taken to avoid all possible sources of contamination of food and drink by tubercle bacilli. Dust, sputum droplets, contaminated flies, soiled hands and articles of various kinds may be the means of introducing bacilli of human origin into food and drink. Efforts should also be directed to exclude the carrying of bacilli into the mouth in more direct ways. The possibility that tuberculosis, pulmonary and otherwise, in reality is of intestinal origin oftener than expected hitherto clearly does not tend to essentially alter in any way the usual preventive measures now in practice. As to milk and other products of tuberculous cows, our attitude, on the whole, will remain unchanged and the practical procedures will depend, as heretofore, on the view taken as to the disputed question of the infectivity for human beings of bovine tubercle bacilli.

Calmette and Guérin have shown also that animals may survive the single introduction of tubercle bacilli into the stomach, the resulting pulmonary lesions healing completely. Such animals are now immune to tuberculosis. The bearing of this demonstration on the human disease we propose to discuss later.

THE NEW BUILDINGS OF THE HARVARD MEDICAL SCHOOL.

It is the general opinion of all who have had the pleasure of seeing them—and this includes the visitors to the memorable Boston session of the American Medical Association—that the new buildings of the Harvard Medical School are the most beautiful academic or public buildings in America. It is pleasant to note that, in their construction, usefulness for the varied purposes of a great medical school has not in any way been sacrificed in order to have architectural beauty and distinction. The architects have succeeded admirably in combining perfection from the utilitarian as well as from

2. Ann. de l'Inst. Pasteur, 1905, vol. xix, and 1906, vol. xx, 609

the architectural point of view. As is reported in detail in this issue,[1] these buildings have now been dedicated with appropriate ceremonies to the purpose for which they were designed and they are now in use for the education of medical students and for medical investigation. Medicine has received a large addition to its resources in this country and all friends of medical progress unite in grateful thanks to the persons who gave the money necessary and in congratulating Harvard Medical School on the completeness and permanence of this part of its external equipment.

So far as the buildings necessary for instruction and investigation in the sciences fundamental to clinical medicine are concerned, this school is now in a most favorable and enviable situation. But medical education and investigation require much more than great buildings. In order that buildings like those at Harvard can be put to their highest usefulness, there must be liberal endowments to pay the men who are to work in them and to furnish the equipment and supplies with which to work. Undoubtedly the same spirit of altruism that prompted wealthy men and women to build the monumental structures just dedicated to medicine in Boston will result in adequate recognition of the choice opportunity and privilege here offered to put more money to the best possible use. And it should be emphasized that an institution requiring the bachelor's degree for entrance on medical work, and possessing such an incomparable group of buildings as Harvard now does, will be expected to do far more than to carry on a high grade of undergraduate medical instruction. Here, if anywhere, should flourish scientific investigation in medicine and special opportunities should be offered not only recognized successful investigators, but also those who promise to develop into such.

Finally, a word in regard to clinical medicine at Harvard. The buildings just dedicated do not provide for clinical work. From recent public utterances by members of the Harvard faculty, it appears that at present the facilities for clinical work, though known to be of high order, are not altogether satisfactory. The hospitals and dispensaries at present are far removed from the medical school proper. This in itself is undesirable. We see, then, that the new Harvard buildings are built for the future to which the friends of Harvard look with hope for adequate endowment, on the one hand, and better provision for clinical medicine, on the other. May these hopes be realized soon.

THE ALCOHOL QUESTION.

At the recent meeting of the British Medical Association the vexed question of the value of alcohol generally and of its use as a drug was dealt with at various times. We referred two weeks ago to the decreased use of alcohol and the increased use of milk in the London hospitals, as reported by Sir Victor Horsley at the luncheon given by the Canadian Temperance Union. Sir Victor Horsley, continuing this subject, said that he not only regards alcohol as the most potent bane of civilization and the cause of physical and mental deterioration of a not inconsiderable portion of the British race, but, further, that he is able to see very little good in alcohol as a drug. In cases of shock subsequent to a severe operation he recommends the employment of another drug than alcohol. The latter he condemns in unsparing terms.

Prof. Sims Woodhead, of Cambridge University, England, took the ground that if it can be proved that alcohol is a remedial agent in any disease, let it be used, but until it has been so proved it should not be employed. He claimed that up to the present time experiments in this direction have obtained such comparatively slight results that they afford no basis for asserting that alcohol has any definite value as a drug. Indeed, investigators working under seemingly like conditions have come to conclusions so diametrically opposed that they have effected little more than to bring confusion to the minds of seekers after the truth.

In the section on therapeutics, Dr. Blackader, of McGill University, expressed the opinion that the action of the heart stimulated by alcohol has been overestimated and that it is sometimes feeble and transitory. The action on the nervous system is more complex, but it is certainly depressing on the centers of judgment, discernment and self-control. Alcohol in medicinal doses increases the bactericidal powers of the blood, while a long series of experiments has shown that large doses in infectious diseases increase the power of the disease poison. It has a food value and, used in fevers and in cases of exhaustion or of indigestion, may be of marked benefit, as it makes no tax on the organs of digestion, but, on the contrary, favors secretion and favors action on the hepatic cells.

Dr. Meltzer, of New York, was far more decided in his support of alcohol as a drug. He asserted that those who opposed its use in disease were those who had never made practical experiments, and that he placed no value on statistics. He drew attention to the fact that, as a rule, German investigators do not believe in the harmfulness of alcohol. In his opinion, alcohol, judiciously used, is capable of stimulating the heart to activity and supports immunity in infectious diseases. Alcohol in health may be a poison, but in disease it is beneficial.

Dr. W. E. Dixon, Cambridge, England, pointed out that the heart rate is no criterion as to whether alcohol stimulates the circulation, that the accelerating action of alcohol on heart rate is due to its stimulating effect on the medulla. According to Dr. Dixon the conflicting results obtained by different investigators are due to the fact that they undertake their experiments on animals under the influence of an anesthetic, which greatly neutralizes the action of the alcohol. Another point to which he drew attention was that in order to accelerate the action of the heart it is necessary to give an exact small dose of alcohol, and that but a slight increase over this quantity produces decided slowing. In his opinion, if a man who is suffering from disease is accustomed to the use of alcohol he should not be completely restricted from its use when sick, and a man suffering from delirium tremens should be given alcohol.

---

[1] See page 1113.

Dr. Osborne, of New Haven, thought that alcohol should be regarded purely as a drug and that its well-known harmfulness when used as a beverage to excess should be set aside when discussing its therapeutic action. There are no pathologic disturbances when alcohol is used as a drug, and, therefore, it should be thus used in cases which call for its employment. He held that it is harmful when employed solely as a cardiac stimulant, merely acting as a whip to an already overstrained system. The opinion was practically unanimous that the employment of alcohol in cases of delirium tremens should be condemned, and Dr. Rose Bradford, of London, took the occasion to warn medical men against a custom which prevails somewhat widely of recommending alcohol to convalescent patients, and especially to women.

The discussion has not increased our knowledge on the subject to any appreciable degree. To all intents and purposes, so far as the elucidation of moot features of the alcohol question is concerned, we are where we were.

FOOTBALL FATALITIES.

The newspapers are already announcing deaths from football, and yet the season is only just opened. It was hoped that the modification of the rules effected by the intercollegiate committee last winter would be adopted and that they would eliminate many of the injuries and all of the serious accidents. Apparently in some places they have not been adopted or have failed to accomplish this purpose. Such modifications as have been made were only as the result of a large amount of pressure brought to bear on the rules committee by medical journals and newspapers, by the protests of faculties and alumni and by the popular feeling that no sport is worth so many lives as football has been costing in recent years.

It is rather difficult for most people to understand why there should be so much insistence among college men on the necessity for continuing Rugby football since, as the game has developed here in America, it has become inevitably bound up with so many rough features. Radical modification of the rules, such as would make the game much less rough, has always been opposed on the grounds that this would so lessen the interest in the sport as to cause it to cease to be the drawing card for large audiences that it now is. It is well known that college athletics derive their main support from the large gate receipts obtained at football games. To the physician it seems utterly absurd to urge that a question of money such as this should stand in the way of modification in a university sport that is intended to save lives and to prevent accidents that produce permanent injury. But even the argument itself with regard to gate receipts on the drawing power of football, irrational, indeed ludicrous as it is, loses all its force when the records of the attendance at English football games are carefully studied. The open game of football in England, which has nothing like the fatalities of our American Rugby, draws even larger crowds. The record attendance at a London football game is over 110,000 and frequently there are 50,000 people present. It is evident then that this argument which has so far had so much weight with college men is simply founded on the lack of knowledge of football conditions elsewhere.

If we are to have this year a repetition or an approximation of the awful record of recent years and of last year especially, it will practically amount to a conviction of our university authorities of lack of power to control certain of the vicious elements in student human nature. If gate receipts are to continue to be a supposed justification for rough play that draws a crowd, then the epithet of Maxim Gorky, which created so much resentment last summer, can not be gainsaid, i. e., that we are an essentially brutal people, since we delight in stories of cruelty and bloodshed in newspapers and find pleasure in spectacles in which life is put in danger.

PATHOLOGISTS IN HOSPITALS FOR INSANE.

The movement to provide for the services of pathologists in hospitals for the insane appears to be extending. Thus Illinois has arranged[1] for civil service examinations to select such assistants. While the complete plan for this important addition to the service of these institutions has not been made public (so far as we are aware), it is evidently the intention to make the laboratory at one of the hospitals the central laboratory through which the work in the other institutions may be stimulated and in a measure directed and coördinated. At all events, largely, we believe, as the result of the activities of the Board of Charities under the high-minded guidance of its president, Dr. Frank Billings, a new factor enters into the work of the Illinois hospitals.

In the aggregate the general result of this new departure should be to put the daily routine work of the institutions on a higher plane than can be hoped for in the complete absence of the stimulus and interest that come from study and investigation. It has frequently been pointed out that the best clinical work, diagnostic and therapeutic, is done in those clinics that associate the treatment of disease with teaching and investigation. The patients, then, are sure to receive almost immediate benefit, mental and physical, from the introduction of progressive methods of study in the hospitals for the insane.

---

[1] The Journal A. M. A., Sept. 15, 1906, page 868.

In the next place, continued, careful study of the rich material in these institutions increases, little by little, our knowledge of insanity and of nervous and other diseases, and among the facts thus gathered many may prove to have far-reaching future importance. Furthermore, the establishment of positions like those now in mind should increase the real opportunities for research, and the more numerous and attractive such opportunities the more likely that men with the power of accomplishment will seek them, and the greater the chance of securing for psychiatry the occasional man of genius who can make discoveries and develop new lines of research.

Undoubtedly, the two most important steps that a state hospital for insane can take is to divorce its management from the baneful influence of "politics" and to provide the men and the means to place its psychiatry on a firm, progressive basis. Unless the first step is taken, it is exceedingly difficult, if not impossible, to take the second.

THE SCIENCE AND ART OF EATING.

Our Athenian contemporary, Professor Bedelar Maturin, has a hobby which he rides on every possible occasion—the exploitation of the work which Brillat-Savarin wrote a century ago on "The Physiology of Taste." The latter believed that human beings should cultivate the wholesome enjoyment of life; that the education of the tastes and the appetites should be an index of the degree of civilization. The man of good instincts and refinement should know how to eat and drink, to converse (a lost art to-day), to appreciate a beautiful landscape, to enjoy the fragrant flowers—in all things to deport himself sanely and soberly. Like the much-maligned Epicurus of old, Savarin was an exceedingly temperate man. They both comprehended well, wise philosophers as they were, that true pleasure lay not in gluttony and other inordinate appetites, but in the knowledge and practice of reasonable conduct in all the manifold aspects of existence. "The love of good living is not merely a physical, but an intellectual and a moral quality, as well, almost deserving to rank as a virtue." We would omit the "almost." Savarin's book (which de Balzac termed "adorable") was written with a double object in view: "to lay down the fundamental theory of gastronomy, so that she would take her place among the sciences in that rank to which she has an incontestable right," and "to define with precision what must be understood by the love of good living, so that for all time that social quality may be kept apart from gluttony and intemperance, with which many have absurdly confounded it." Lest the reader imagine Savarin's work to be lacking in profundity, we quote the following: "The most momentous decisions of personal and of national life are made at table." "But for life the universe were nothing; and all that has life requires nourishment." "The fate of nations depends on how they are fed." "The man of sense and culture alone understands eating." "A good dinner is but little dearer than a bad one." These and other aphorisms in the book are exceedingly practical: "One should eat slowly and in minute portions;" this is, in essence, the Fletcherism of today. "Digestion, of all the bodily functions, has most influence on the *morale* of the individual." "The great majority of us eat and drink too much;" is not this dictum announced to-day with trumpets, as if its utterance had never before been essential? Savarin was probably the first exponent of the modern science and art of gastronomy, which has been enormously developed since his day. But among the many tomes on food and dietetics now extant, among the mass of literature on practical cookery to be found in the magazines, no writing will be found more scientific or more useful than that which this genial and kindly Frenchman, a century ago, left us for a legacy of good cheer. If it were more read and its precepts followed, there would be less dyspepsia, less crime and fewer divorces.

THE OPERATIVE TREATMENT OF VARICOSE VEINS OF THE LEG.

Varicose veins in the lower extremities occur as the result of varied conditions, some inflammatory, some of less definite character. It is probable that hereditary tendency is of etiologic significance in this connection. The disorder is due to incompetency of the valves whose function it is to prevent the stagnation of blood in vessels, the contents of which must be propelled in opposition to the force of gravity. Phlebitis, complicating or following pregnancy, or some operative procedure or acute infection, is the cause in a considerable proportion of cases. The erect posture long maintained in predisposed individuals will account for another group of cases. Palliation can be afforded in many instances by means of the recumbent decubitus or elevation of the affected member or members, or by the use of elastic constriction, but operative intervention becomes necessary for radical relief, the object being to effect occlusion of the saphenous vein. By one method of procedure the superficial veins of the affected part are divided between ligatures, while by another the saphenous vein and its branches are excised throughout a varying extent, and by a third the vein is divided between ligatures. In a recent communication dealing with this subject Dr. Robert T. Miller[1] reports the results of operative treatment in 128 cases of varicose veins of the lower extremities and associated disorders observed at the surgical clinic of the Johns Hopkins Hospital, some of which were followed for periods of ten years and more. One hundred and seven of the cases occurred in whites, and 21 in colored individuals; 73 in males and 55 in females. The largest number of cases in any decade developed between the years of 20 and 29, namely 41; 81 developed before 40, and 37 after. The disorder appears thus not to be a manifestation of senility. In 40 cases a definite history of phlebitis was obtained; pregnancy was responsible for the condition in 25, typhoid fever in 9, erysipelas in 2, pneumonia in 1, acute enteritis in 2, operation in 1. In 88 cases no inflammatory factor could be ascertained; among the causes assigned were constipation, excessive walking or standing, pelvic tumor. The right leg was involved alone in 21 cases, the left alone in 25; both legs were involved in 74, and in the majority of these the left was the more affected. The leg was involved alone in 91 instances, the leg and the thigh together in 25, the thigh alone in 1. In addition to the favorable results from the operation named first it has the advantage of avoiding division of large cutaneous nerve-trunks, with secondary anesthesia or hyperesthesia. Also there is no subsequent edema. Further, the operation can be performed readily under local anesthesia. Finally, there is less likelihood of recurrence of the condition after adequate excision than after ligation. Pulmonary embolism—characterized by sudden dyspnea, cyanosis, tachycardia, signs of collapse, elevation of temperature—may occur as a complication of any of the modes of operation mentioned.

---

[1] Bull. Johns Hopkins Hosp., September, 1906, p. 289.

THE PASSING OF DOWIE.

In its editorial notice of "The Passing of Dowie" the Chicago *Tribune* remarks that there is for him in his downfall perhaps more a feeling of pity than exultation, even among those who have regarded him from the outset as among the chiefest of impostors. To a certain extent this is true, the fall is a severe one, but, after all, it is not more, or even as much, as the man deserves or as his dupes have suffered. It is said that, while he deceived others, he was also himself deceived, that he had faith in himself and was the victim of a delusion. That may be the case. A man is capable of creating a delusion in himself, as he may repeat a lie so often that he finally actually believes it is truth. Dowie may have been deluded, but there was certainly a vast amount of method in his delusions. During the past dozen years or more he has been appropriating the savings of thousands of honest dupes, and what he has not spent of it in personal extravagance and luxury he has claimed as his peculiar personal property, making his self-styled prophetship a matter of the most outrageous personal profit. There have been many of his kind. The starting of a new religion is an old confidence game, but there have been very few in which the financial motive has been more prominent and which have been worked out with such success. We might except Eddyism, perhaps, of which it is hard to say whether the female figurehead or the very evident working syndicate are the true "profits." That, too, must come to its end, though it may develop into a sort of religious sect, as has Mormonism, or may at least continue in a more or less modified form, for some time to come. Even now its doctrines are something like the so-called British constitution, modified to meet every case that may arise. Its projectors and managers do not apparently, like Dowie, rake in the savings of the poor. They take the shekels of the well-to-do, for whom their system is specially elaborated, with its catering to the lust of the eye and the pride of life and its easy-going denial of sin and pain. In some respects, therefore, Dowie was the more contemptible sinner, and his earlier passing out of pernicious activity is the less to be regretted. His sect for a while may continue, but the medical fallacies and absurdities, on which it was so largely based and which have been, to a great extent, responsible for so much individual human suffering, have already practically disappeared.

MEDICAL FALLACIES.

In the last number of the *American Magazine* is an article on popular medical fallacies by Dr. L. K. Hirshberg which, while rather nihilistic in tone, is, on the whole, commendable. A number of popularly accepted propositions with regard to medical matters are directly contradicted. Virchow used to say that all of the medical fallacies accepted generally by the people have been at one time doctrines recognized by physicians. Undoubtedly many of the present-day popular medical fallacies even yet are accepted by certain physicians, and it is this that helps to keep them alive. For instance, there are still physicians who say that boils are always a manifestation of a blood disease. While it is true that a run-down condition will predispose to the appearance of boils, these are practically always due to infection from without. It is suggested that men suffer more from boils on the neck than do women, because the former wear starched collars that are likely to produce lesions through which infective agents find their way beneath the skin. The possibility of taking cold in a boil or in a cut or wound, which is believed in by most people, is thrown out as one of the old-fashioned notions that we are through with. Certain popular remedies, such as sage and other old-time teas, are discussed, and whatever efficacy they have is attributed to the true cause—the hot water employed in making them. Of course, the mental suggestion that something has been done which is likely to be beneficial removes the despondency that comes with illness of any kind and helps to restore the patient to normal conditions. In the same way the vaunted efficiency of many liniments is attributed rather to the rubbing associated with their application than to any remedial virtue that there may be in the drugs of which the liniments are composed. The popular impression that there is a specific remedy for each disease and that nothing but this specific will cure it is at the bottom of many of these fallacies. This was an old-time medical notion that has not as yet gone out entirely, but whose disappearance will do much to make popular medical ideas more sane and sensible.

THE EXISTENCE OF HYDROPHOBIA.

The lay press of late has been considerably interested in certain allegations published in the organ of the humane societies that no such disease as hydrophobia exists, and the idea is naturally acceptable. The eminent physicians who are quoted as questioning the existence of the disease can properly speak from their own experience and have a right to any honest opinion they may hold on the matter, but to support such claims by saying, as some of them are said to do, that they know of no other physician or surgeon who has seen a case, would imply a more limited acquaintance with the leading men of the profession and their work than ought to be the case. There have been plenty of cases of hydrophobia published in the medical press by eminently respectable authorities whose word and judgment on any other disease would not be questioned—and why should they be in this? Some of these cases reported leave no ground for supposing that any mental element entered into the causation of the symptoms, the victims even dying without any recognition whatever of the true nature of their disease. If there are any of the obscurer nervous diseases that are clearly established as clinical entities, hydrophobia is one, and its comparative rarity, for which we ought to be sufficiently thankful, does not in any way affect the fact that such a disease exists.

Medical News

ALABAMA.

College Opens.—The forty-first annual session of the Medical College of Alabama, Mobile, opened October 3.

Hospital Notes.—Jefferson County Medical Society has endorsed the proposed charity hospital to be erected in Birmingham, and a committee has been appointed to frame a bill providing for the erection and to decide whether bonds shall be issued to cover the cost of constructing and maintaining the hospital.

State Did Not Make Out Its Case.—In the case of the state of Alabama against Drs. Philander S. Boyd and Breckinridge J. Duckett Florence, charged with manslaughter due to the use of a too strong solution of carbolic acid, the judge closed the case of the state September 20 by taking it out of the hands of the jury and dismissing the defendants, as the experts agreed that the death was not due to carbolic acid poisoning.

CALIFORNIA.

Fined for Selling Impure Milk.—Emmanuel Fagundes, Oakland, was fined $100 in the police court September 14 for selling milk which was found to contain two-fifths added water.

To Equip Laboratories.—The San Francisco board of health has called on the board of supervisors to provide $6.000 for the equipment of the chemical and bacteriologic laboratories of the board.

Diphtheria.—The Grant public school, Oakland, was closed September 15 by order of the board of health on account of an epidemic of diphtheria among the pupils. More than 20 cases have been reported during the last few days.

Isolation of Contagious Diseases.—The board of supervisors of San Francisco has passed the ordinance proposed by the health board, authorizing the latter to remove at its discretion patients suffering from contagious disease.

Hospital News.—Mrs. Herbert Kraft has given a site for a hospital at Red Bluff, to be organized under the name of the St. Elizabeth's Hospital and to be conducted by the Sisters of Mercy.——A county hospital for San José County is soon to be erected at a cost of $65.000 on the site of the old county building, San José, which was destroyed by the earthquake last April.——A hospital is planned at Grass Valley, to be under the charge of Dr. John T. Jones.

Health Report.—The nineteenth biennial report of the State Board of Health was submitted to the governor September 15. The chief recommendations of the board are a larger appropriation for the State Board of Health, the more rigid enforcement of sanitation at summer resorts, and that vaccination ordinances be more strictly enforced. Many and extensive improvements are recommended for the State University at Berkeley, where sewerage is reported to be bad. A hospital for the students is also recommended. During the year 20,909 births were reported, equivalent to 11.7 per 1,000. The deaths during the same period were 27.026.

Coroner's Report.—During the fiscal year 1905-06 the coroner of San Francisco County reports 2,196 deaths, 428 of which were due to the earthquake and fire of April 18. The remainder are classed as follows: 1,200 from natural causes, 340 from accident, 177 from suicide, 36 from homicide, and in 11 cases the cause of death was undetermined. Of the suicides 142 were males and 45 females; illness was given as the cause of the greatest number of suicides, drinking next, insanity third, and finally financial troubles. By occupations laborers headed the list, housewives came next and clerks and bartenders third and fourth respectively. No lawyers or physicians appeared on the suicide list.

COLORADO.

August Deaths.—The total number of deaths in the state during August was 856, equivalent to an annual death rate of 15.52 per 1,000. Of the deaths 46 were due to typhoid fever, 9 to diphtheria and 8 to scarlet fever.

Comparative Morbidity During August.—During August 461 cases of typhoid fever were reported, an increase of 291 cases as compared with July; 91 cases of scarlet fever, a decrease of 14 cases; 28 cases of diphtheria, a decrease of 3 cases, and 4 cases of smallpox, a decrease of 26, as compared with the previous month.

Physicians Injured.—Dr. H. Calvin Lefurgey, Durango, while making a professional call, was thrown from his buggy and suffered a comminuted fracture of the left arm.——Dr. Wilbur W. Bulette, Pueblo, while driving with Dr. William H. Campbell, few miles north of Pueblo, was thrown from the buggy in a runaway accident and sustained severe contusions. He was removed to the Pueblo Hospital.

New Hospital.—A new dispensary building is to be erected in connection with the Denver and Gross Medical College, to cost about $16.000. Land has been secured adjoining the present laboratory building and work will soon be initiated.——Ground was broken September 20 for a sanatorium to accommodate 52 patients at Glenwood Springs, to be under the charge of Dr. William F. Berry.

DISTRICT OF COLUMBIA.

Personal.—Dr. George F. Simpson, inspector in the district health department, has resigned to take effect September 28.——Dr. T. S. Vincent, Washington, fell from the second story window of a hotel at Braddock Heights, Md., and broke his right leg at the ankle.

Health Conditions.—In the report of the health department for the week ended September 22 it was announced that the improvement in typhoid fever conditions was more pronounced than at the close of the previous week. There was reported a decrease in the number of cases from 288 to 280. During the week 37 new cases were reported and 45 patients discharged, with only 2 deaths having occurred. No new outbreak of smallpox was reported. The total deaths numbered 127, as compared with 108 during the previous week and 104 as compared with the corresponding week of 1905. The principal causes of mortality were: Consumption, 16; heart disease, 13; nephritis, 10; malignant disease and diarrheal diseases, each 9; pneumonia, 6, and cerebral hemorrhage and bronchitis, each 4.

ILLINOIS.

Hospital to be Built.—The plans and specifications for the Graham Hospital, Canton, are nearly completed and construction will be begun this fall.

Personal.—Dr. Josiah M. Cody, Tremont, has been elected physician for the Tazewell County Farm.——Dr. Coleman J. Eads, Oquawka, has been obliged to discontinue practice on account of ill-health, and has sold his property to Dr. C. E. Kaufmann.——Dr. James W. Sanders, Decatur, has been elected a member of the board of directors of the Bethsaida Hospital Association.

Pills Prohibited.—At a meeting of the Streator city council, September 19, an ordinance was passed prohibiting the posting of any handbills or other advertising matter for "patent medicines," etc., in any street or public place in Streator, and also prohibiting the distribution of any samples of medicine within the city limits. The fine for violation of this ordinance is not less than $5 nor more than $50 for each offense.

Chicago.

Automobile for Health Department.—The council finance committee, on September 28, authorized the health commissioner to purchase an automobile for the emergency inspection work.

Personal.—Dr. James Alexander Harvey returned from Berlin, October 1.——Dr. and Mrs. Arthur R. Elliott are expected to return from Europe this week.——Mr. John Lynn Thomas, Cardiff, Wales, spent a few days in Chicago last week and was entertained by the surgeons of the city.

Building Commissioner Enforces Regulations.—By order of the building commissioner, on September 27, the three upper floors of the Jenner Medical College were closed for several hours, on account of failure to comply with the provisions of the building laws. The commissioner ordered two fire escapes put in the building, more exits cut through and exit signs placed.

Health of the City.—During the week ended September 29, 44 fewer deaths from all causes were reported than during the week previous, although there were 15 more deaths from violence. The important death causes showing decreases were: Acute intestinal diseases, 23; consumption, 21; apoplexy, 6; typhoid fever, 5; cancer, 3; heart disease, 2, and diphtheria, 1. The total number of deaths for the week was 538, equivalent to an annual death rate of 13.69 per 1,000. There were 57 more deaths than for the corresponding week of 1905. The principal death causes were: Acute intestinal diseases, 99; consumption, 57; violence (including suicide), 54; nephritis, 47; pneumonia, 37; heart diseases, 34, and cancer, 22. There were 12 deaths reported from suicide, an increase of 7 over the preceding week.

IOWA.

Site for Hospital.—It is reported that the state board of control has decided to locate the State Tuberculosis Sanatorium on the Grant farm, near Fort Dodge.

Typhoid Fever at Dubuque.—Owing to the prevalence of typhoid fever in Dubuque, the people have been warned to boil the drinking water. The disease is said to be prevalent in all sections of the city.

Bacteriologic Report.—The secretary of the State Board of Health reports that during August 382 examinations were made in the bacteriologic laboratory. Of these 85 were for diphtheria, 69 for typhoid fever and 184 for tuberculosis.

Medical College Opens.—The Sioux City College of Medicine and Surgery opened for its annual session September 19 with addresses by Dr. George S. Browning and the dean, Dr. Hial S. Wheeler. The following faculty changes were reported: Dr. R. M. Conmey, professor of physiology, and Dr. G. E. Barr, assistant in hygiene.

Personal.—Dr. and Mrs. William Cammack, Salem, have started for London en route for South Africa, where they enter the service of the American Board of Commissioners for Foreign Missions.——Dr. A. W. Crary, Boone, has been made a medical instructor in the medical department of the State University, Iowa City.

Hospital Board Meeting.—At the annual meeting of the board of the Eleanor Moore Hospital, Boone, held September 17, the following directors were elected: Drs. Alpheus A. Deering, George D. Rowe, J. Henry Nordstrom, George H. Stanger, Lemuel A. Barrett, Evalene Peo, Clyde W. Payne and Kate S. Harpell. During the year more than 2,000 patients were treated and more than 100 operations performed.

KENTUCKY.

Money for Sanatorium.—At a meeting of the board of directors of the Kentucky Anti-tuberculosis Association, September 21, it was decided to attempt to raise the $11,000, the balance necessary for the erection of the proposed tuberculosis sanatorium.

New Hospital.—A contract for the erection of the building of the Good Samaritan Hospital, Lexington, has been let. The building will cost $12,000 when completed.——The new King's Daughters' Hospital, Shelbyville, was formally opened September 19. The building is three stories high with 12 rooms, including two wards of three beds each.

Personal.—Dr. Florence Meder, who succeeds Dr. Minnie C. Dunlap at the Eastern Kentucky Asylum for the Insane, Lexington, has arrived and assumes her new duties as third assistant physician. Dr. Dunlap has been transferred to the Western Kentucky Asylum for the Insane, Hopkinsville.——Dr. Donald R. Jacob has been elected president, and Dr. Oliver H. Kelsall, secretary, of the Louisville Academy of Medicine, and Dr. Gavin C. Fulton has been re-elected treasurer of the organization.

Typhoid Fever and Diphtheria.—Mercer County is said to have an epidemic of typhoid fever, and it is reported that there are at least 200 cases in the county and in Harrodsburg.——An epidemic of typhoid fever is said to be raging at Hindman.——Diphtheria in malignant form is reported to be epidemic in the western part of Cumberland County.——Typhoid fever is reported to be epidemic and on the increase in the eastern part of Bath County. Diphtheria is also reported to be prevalent throughout the county.

MARYLAND.

New Hospital.—Ground was broken September 19 for the new wing of the Frederick City Hospital, to be erected by Mrs. Margaret Hood as a memorial to her late husband, James Miflin Hood.

Automobile Accident.—Drs. Henry P. Fahrney, Frederick, and Morris A. Birely, Thurmont, while making a professional call in an automobile belonging to Dr. Fahrney, were seriously injured by the overturning of the machine at the foot of a steep hill.

State Society Meeting.—The semi-annual meeting of the Medical and Chirurgical Faculty of Maryland was held September 27 and 28. In the address of welcome, the governor suggested that the portraits of two of the most eminent founders of the faculty be placed in the senate chamber. Dr. Charles M. Ellis, Elkton, offered a resolution suggesting that $200 be appropriated to cover the expense. A committee was selected composed of Drs. Charles M. Ellis, Elkton; Eugene F. Cordell, William H. Welch, Herbert Harlan and Robert W. Johnson, Baltimore, to select five or more names from the 101 founders to be submitted to the faculty, which will at that time select the two founders to be honored.

Baltimore.

New Municipal Hospital.—The members of the Municipal Hospital commission have decided on the plans of the building to be constructed for the isolation hospital, for which $25,000 was appropriated by the city council.

University Reorganized.—The medical faculty of the Baltimore University School of Medicine has reorganized and an effort will be made to secure re-establishment of membership in the Association of American Medical Colleges. It is said that a new hospital and medical school building is to be erected in the northern part of Baltimore and that the institution will open under the new régime this fall. The organization of a dental school is also being considered.

Typhoid and Diphtheria Increase.—The report of the health department for the week ended September 22 shows an increase in the number of cases of diphtheria and typhoid fever as compared with the corresponding week of last year. Deaths from all causes for the week were 212, or 16 more than for the corresponding period of last year. Of these, consumption caused 29; diarrhea, 24; Bright's disease, 16; cancer, 13; heart disease, 12, and congenital disability, 10. Twenty-four cases of diphtheria were reported and 51 cases of typhoid fever, 12 more than for the corresponding week of last year.

Personal.—Dr. and Mrs. John C. Hemmeter have been the guests of Dr. C. K. Pell, head of the department of medicine of the University of Amsterdam, and Prof. K. Schapp, Groningen, where they attended the opening ceremonies of the university.——Dr. Ira Remsen has returned after a summer in Maine.——Dr. Howard A. Kelly was given the honorary degree of LL.D. at the four hundredth anniversary of the foundation of the Aberdeen University.——Dr. Albertus Cotton has returned from Europe.——Dr. Llewellys F. Barker was taken ill at the opening exercises of the Harvard Medical School and was taken to a hospital at Brookline, Mass.

MASSACHUSETTS.

Leper Alleged to be Cured.—It is reported that Mary Barros, a leper in Wareham, after a year's incarceration and two years' surveillance at the State Leper Colony, Penikese Island, is to be released as cured.

School Inspectors Appointed.—Drs. William Galvin, Henry J. Millard, Philip Potter, George A. Fagan, Alfred A. Harper, Wilfred A. Brosseau and Ransford D. Canedy have been appointed inspectors of schools at North Adams.

New Hospital.—The plans have been accepted for the new Franklin County Public Hospital, to be erected in Greenfield at a cost of about $40,000. The building first to be erected will contain accommodations for about 30 patients.

Personal.—Thomas J. Bean, Lowell, has been made a member of the board of health, vice Dr. William B. Jackson.——Dr. Frank L. Morse has been appointed city physician of Somerville, but will continue also as bacteriologist of the city.——Dr. Laura A. C. Hughes, Boston, was elected president of the Spanish-American War Nurses' Association, September 6.

Pure Milk for Infants.—The Cambridge Medical Improvement Society has finished its first year's experiment of providing pure and sanitary milk for infants, during the summer season, which closed September 15. The city appropriated

$1,000 for the experiment, $800 of which was expended. During the year 35,000 bottles of modified milk were distributed under the auspices of the city.

Close of Floating Hospital Season.—The trustees of the Boston Floating Hospital announce the close of the season's work and issue a circular giving the comparative statistics for the period of four weeks on the old and new boats, showing the increased work that the institution has been able to accomplish with the new boat.

	Old boat.	New boat.
Number of days' care given to permanent patients..	1,436	2,958
Number of trips made by day patients	1,298	1,086
Number of trips made by mothers of sick children..	1,151	1,349
Number of trips made by well children under six years of age, who could not be left at home......	477	690

Medical School Inspection.—The Springfield Board of Health has had printed a circular containing rules for medical inspection, which details the duty of inspectors as follows: The identification of pupils requiring medical aid; the detection of children suffering from communicable diseases; the detection of other than communicable diseases and ailments, and the detection of defective eyesight, hearing or other disabilities. It is directed in the circular that the following described children should be sent to the inspectors on Monday and Thursday morning of each week: Every child returning to school after an illness or absence from unknown cause without a certificate from the board of health; every child suffering from contagious or infectious disease, or showing signs of ill health, and every child who returns to school after having been excluded by the medical inspectors. Children showing signs of the following diseases are to be sent home immediately: Smallpox, scarlet fever, measles, chickenpox, tuberculosis, diphtheria, influenza, tonsillitis, whooping-cough, pediculosis, scabies, trachoma, ringworm and impetigo contagiosa.

MICHIGAN.

Interurban Railway Surgeons.—The Michigan United Railway has established a complete surgical system over its lines and has appointed the following surgeons: Lansing, Dr. Harry A. Haze, surgeon-in-chief; alternate, Dr. Robert E. Miller; St. Johns, Dr. Samuel E. Gillman; alternate, Dr. W. A. Scott; Jackson, Dr. C. G. Carnell; alternate, Dr. H. Duane Brown; Parma, Dr. Vene D. Farmer; Albion, Dr. Alfred J. Abbott; alternate, Dr. George C. Hafford; Marshall, Dr. L. A. Harmon; alternate, Dr. Frank M. Foote; Battle Creek, Dr. William S. Shipp; alternate, Dr. Clarence S. Gorsline; Augusta, Dr. Charles E. Doyle, and Kalamazoo, Dr. Albert B Cornell; alternate, Dr. Leonard H. Stewart.

MINNESOTA.

Hospital Nearly Ready.—The new Bethesda Hospital, Crookston, is expected to be ready for occupancy about October 1. The building is of white stone, two stories in height, and is equipped with all modern conveniences.

Diphtheria.—Diphtheria in virulent form is reported at Sauk Center.——It is reported that diphtheria exists in three families near East Park, White Bear Lake, and complaint has been made to the board of health that the members of the afflicted families are not quarantined.

Personal.—Dr. Henry M. Bracken, secretary of the State Board of Health, has been elected president of the National Conference of Licensing Embalmers' Boards.——Dr. George H. Freeman, senior interne at the City Hospital, St. Paul, has been selected as senior assistant at the St. Peter State Hospital for the Insane, vice Dr. C. J. Tuomy.

Red Cross Organized.—The Sons of Veterans of Minneapolis have organized a Minneapolis Red Cross Society, with the following officers: Major Thomas T. Wareham, surgeon-in-chief; Capt. George D. Bentley, assistant surgeon; Lieut. W. J. Burns, passed assistant surgeon, and Drs. W. G. Dawson and D. Edmond Smith, contract surgeons.

NEW YORK.

Bequeaths Library.—By the will of the late Dr. Louis A. Weigel, Rochester, his medical library is bequeathed to the Reynolds Library, Rochester.

Boil Water.—The health commissioner of Buffalo announces the presence of the colon bacillus in the city water, enjoins that all drinking water be boiled, and emphasizes the need of a filtration plant.

Personal.—Dr. and Mrs. Henry Adsit, Hornell, have sailed for Italy.——Dr. John L. Heffron, Syracuse, returned from abroad September 15.——Dr. J. Wilson Poucher, Poughkeepsie, returned from Europe, September 18.

New Hospital.—The Ilion Emergency Hospital has been incorporated with a board of 11 directors. An anonymous benefactor has donated $25,000 for the erection of the building, and an acre of land has been offered as a site for the new institution.

Society Changes Name.—The Practitioners' Society of Rochester, composed of women, has been authorized by the Supreme Court to change its name to the Blackwell Society of Rochester, in honor of Dr. Elizabeth Blackwell, the first woman graduate of medicine in America. The change became operative September 8.

After-Care of the Insane—Five months ago the State Charities Aid Association started an organized movement for the after-care of the insane. It had been observed that many persons discharged as cured of insanity soon relapsed when returned to their former surroundings and mode of life; this organization endeavors to follow such patients and to place them in such employment and amid such surroundings as will prevent a relapse. It is claimed that there is a large field for this kind of work and that the organization is accomplishing much good.

Hospital Notes.—The Buffalo General Hospital trustees have purchased for $85,000, 118 feet frontage on Goodrich Street, east on Ellicott, which backs up on the land now owned by the hospital. On this site will be built the Children's Hospital, for which Dr. De Villo W. Harrington made a bequest estimated from $75,000 to $100,000.——The common council of Lockport has directed the city clerk to advertise for bids for a new city hospital to cost $15,000. The city has donated the site and $5,000; $5,000 has been raised by subscription and the same amount was donated by the late Augustus Keep.

Illiteracy.—The second annual report of the state educational department shows that 58 of the 61 counties have a lower proportion of illiterates than New York City in their population over ten years of age. In the state there are 54 illiterates per 1,000 population, and in New York City 81. The average number of illiterates per 1,000 is 59 for the entire state, and there is one illiterate to every 18 voters. Eighty per cent. of the illiterates are of foreign birth, but there are more illiterate children of native than of foreign parentage. There is dire need for the enforcement of the law compelling children to attend school in the rural districts.

New York City.

Bequests.—The will of the late Henry I. Barbey gives St. Luke's Hospital $25,000, the Society of the New York Hospital $20,000, and the Home for Incurables attached to St. Luke's Hospital $10,000.

Health Board Raids Building.—As repeated warnings from the health department to the effect that certain sanitary changes in the building at the corner of Broadway and Canal Street had been disregarded, the police officers of the department drove tenants and help from the building and plumbers were immediately put to work to remedy defects.

Personal.—Dr. Kirke Stanley is at the Harlem Hospital, recovering from a fracture of the base of the skull, supposed to have been due to an assault by a robber, as when he was found his watch and money were gone.——Dr. Charles Senter has been appointed temporary head of the Bronx health department, vice Dr. Gerald M. V. Shiel.——Dr. Robert J. Morrison, Brooklyn, sailed for Europe September 15.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending September 22, 354 cases of tuberculosis, with 154 deaths; 154 cases of diphtheria, with 16 deaths; 134 cases of typhoid fever, with 29 deaths; 59 cases of scarlet fever, with 2 deaths; 55 cases of measles, with 2 deaths; 30 cases of whooping-cough, with 8 deaths; 5 cases of cerebrospinal meningitis, with 7 deaths; and 9 cases of varicella, a total of 800 cases, with 218 deaths.

The Season's Milk Report.—The Nathan Strauss pasteurized milk depots have just completed their fourteenth season. The quantity of milk distributed during the past summer exceeds that of any other season by 471,855 bottles. The total number of bottles given gratis or for which the sum of one cent was paid was 3,142,252, and the number of glasses drunk on piers, from booths and in parks was 1,078,405. The increased demand for this milk makes it evident that the task of supplying modified milk to tenement house babies will soon be beyond the bounds of private charity and it will devolve on the municipality to shoulder the burden. Mr. Strauss has just signed contracts for the erection of a new building on East Thirty-second Street, to be devoted exclusively to the modification and pasteurization of milk.

Typhoid Fever.—From Jan. 1, 1906, up to Sept. 12, 928 cases of typhoid fever have been reported to the sanitary bureau. During the week ending September 8 the greatest number of cases occurred, 81 in all, while during the week ending June 5 there were only 5 cases. The greatest number of deaths occurred during the week ending August 25, 23 being the total. Up to July 14 the number of living cases reported did not exceed 20. Of all the cases reported a large per cent. were residents of tenement houses, and mostly house workers. The department of health examined the blood and urine in over 80 per cent. of the cases reported; in 50 per cent. of the cases the Widal test showed positive and the diazo in 33 per cent. In the majority of the cases the spleen was enlarged and rose spots were present. Water showed as the most common cause in nearly 31 per cent; next, milk, 25 per cent.; while oysters were the least common cause, representing 5 per cent. The board of health of Brooklyn announces that from August 14 to Sept. 2, 1905, the number of cases of typhoid fever reported in Brooklyn was 689, while during the same period this year only 173 cases were reported. This is attributed by the board to the campaign of education instituted last year.

NEW JERSEY.

State Asked to Withhold Allowance.—The commissioner of charities and correction made a report to the governor, September 21, in which he advised the state to withhold the allowance for the support of the insane patients in the Salem County almshouse until proper accommodations have been provided for the patients.

Personal.—Dr. Charles Dingee has been appointed city physician of Burlington, vice Dr. Edmund Eastwood.——Dr. Jacob Hempstead, Paterson, succeeds Dr. Anthony as house physician to the Muhlenberg Hospital, Plainfield, October 1.——Dr. William C. Boone, who resigned from active service on the medical board of the Muhlenberg Hospital in July, after a service of more than 25 years, was appointed consulting physician of the hospital, September 10.——Dr. J. Edward Blair, Burlington, was operated on for appendicitis at the German Hospital, Philadelphia, September 3.——Dr. Albion C. Christian.. Irvington, has returned from a trip to the Pacific Coast.

PENNSYLVANIA.

Typhoid Fever in Pittsburg.—Twenty new cases of typhoid fever were reported to the Pittsburg bureau of health for the 24 hours ended at noon, September 26.

Personal.—Dr. Joseph H. Bittinger has been chosen president; Dr. John D. Keller, vice-president, and G. Harry Jordy, secretary and treasurer, of the Physicians' Club of Hanover. ——Dr. William J. Hanlon, Mount Carmel, is confined to his house on account of illness.

Must Secure Burial Permits.—The board of health of Chester has decided to take legal steps against funeral directors who do not secure burial permits before interring bodies. It is said that a number of physicians of Chester fail to issue necessary certificates, especially in cases of death from diphtheria.

Chi Club Organized.—A number of physicians of Scranton and vicinity, graduates of the Medico-Chirurgical College of Philadelphia, organized a "Chi Club," September 20. The following officers were elected: Dr. Gilbert D Murray, Scranton, president; Drs. Charles P. Stackhouse, Wilkesbarre; William B. Stricker, Nanticoke, and Frank J. Wagner, Carbondale, vice-presidents, and Dr. Thomas Monie, Archbald, secretary and treasurer.

Philadelphia.

August Vital Statistics.—The report of the division of vital statistics for the bureau of health for August shows that 1,905 deaths and 2.604 births were reported.

Druggist Fined for Selling Morphin.—William Frost, a drug clerk, who was arrested, charged with selling morphin without a prescription and without placing a poison label on the bottle, was found guilty and sentenced to pay a fine of $50.

Pure-Food Prosecutions.—Last week, for the first time since the inauguration of the pure-food crusade by Dr. Warren, several cases were tried in the quarter sessions court. Ten men accused of food adulteration pleaded guilty before Judge Martin and were each fined $50 and costs.

Personal.—Dr. Hobart A. Hare narrowly escaped serious injury by being thrown from his automobile in a collision with a trolley car, September 26.——Dr. Howard T. Karsner sailed for Europe, September 28.——Drs. Harris A. Slocum, Ralph W. Seiss, George B. McClellan, A. Allison O'Daniel, James M. Anders and John C. Heisler have returned from Europe.

Physical Culture in the Public Schools.—The superintendent of the city schools, in his report to the board of education, recommends and approves systematic physical culture in the public schools throughout the city. His report provides for the appointment of a director at $2,500, and as many assistants at $1,000 a year each as may be needed. Dr. Brumbaugh mentioned that under the act of March 8, 1901, such instruction is obligatory.

Health Report.—The total number of deaths reported for the week ended September 29 reached 439. This is an increase of 17 over the number reported last week, and an increase of 35 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 17; pertussis, 8; diphtheria, 13; consumption, 52; cancer, 18; apoplexy, 23; heart disease, 35; acute respiratory disease, 38; enteritis, 56; appendicitis, 6; Bright's disease, 27; congenital debility, 14; suicide, 3; accidents, 15, and marasmus, 6. There were 180 cases of contagious disease reported, with 30 deaths, as compared with 190 cases and 20 deaths reported in the preceding week.

Medical Inspection for August.—The report of the division of medical inspection of the bureau of health for the month of August shows that the number of inspections made, excluding schools, was 3.416, and that 494 fumigations were ordered. Eighteen cases were examined for special diagnosis; 182 cultures were taken, 106 injections of antitoxin were administered and 473 vaccinations were performed. In the division of milk inspection 5 584 inspections were made, 107,760 quarts of milk were examined and 40 quarts condemned. The report of the bacteriologic laboratory shows that 606 diphtheria cultures were examined, 552 Widal reactions were performed, 669 quarts of milk were examined, and 92 specimens of sputum. The laboratory supplied 1,708.500 units of antitoxin.

College Openings.—The annual opening of Jefferson Medical College for the sessions was held in the college laboratories, September 24. The introductory student address was delivered by Prof. Howard Hansell.——All the departments of the Medico-Chirurgical College were opened for the session of 1906-07 with the usual exercises, September 25. The annual introductory address was delivered by Dr. John V. Shoemaker, who spoke on "The Scientific Foundation of Modern Treatment of Disease."——The one hundred and sixty-seventh annual session of the University of Pennsylvania began September 28. The opening exercises were held in the new medical laboratories, and the opening address was delivered by Dr. Charles Frazier, dean of the medical department.——The fifty-seventh annual opening exercises of the Woman's Medical College of Pennsylvania were held in the college building, September 26. Dr Clara Marshall, the dean, made the introductory address, and the annual oration was delivered by the professor of pathology, Dr. Aloysius O. J. Kelly.

TENNESSEE.

Hospital Addition.—An addition is to be erected to the St. Thomas Hospital, Nashville, increasing the capacity of the hospital about 60 per cent., at a cost of $60,000.

Communicable Diseases.—The opening of the public schools of Gallatin has been suspended on account of diphtheria.——An epidemic of typhoid fever has developed in the east section of Owingsville, where thirty cases are said to exist.

To Hunt Down Illegal Practitioners.—The Dickson County Medical Association, at a recent meeting, resolved to bring to justice every individual in Dickson County endeavoring to vend or practice medicine contrary to the statutes of the state.

Personal.—Dr. J. M. Trout, Jackson, is in New York City on his way to Europe, where he expects to remain about a year.——Dr. Frank S. Raymond, Memphis, president of the Memphis Board of Health, has applied for leave of absence on account of ill health.

College Opens.—Meharry Medical College, the Department of Medicine of Walden University, Nashville, opened for its thirty-first annual session, September 5. The faculty has been reinforced by the addition of Prof. C. H. Elliot, who will take charge of the chemical laboratory.

Academy Incorporated.—The Nashville Academy of Medicine was incorporated September 5 by Drs. Marvin M. Cullom, G. C. Savage, Lucius E. Burch, William R. Sifford, Holland M. Tigert and Charles A. Robertson. The purpose of the organization is said to be interchange of ideas and a general furtherance of the general science of medicine.

TEXAS.

Smallpox.—Four cases of smallpox have been discovered near Tyler. The patients have been isolated and are under quarantine.

Asylum Completes Year Without Deficit.—The superintendent of the Northern Texas Hospital for the Insane, Terrell, reports that for the sixth consecutive year, the business of the institution has been so managed that the appropriations made by the legislature have been sufficient to meet the expenses of the institution.

Physicians Must Register.—At a meeting of the San Antonio Board of Health, it was decided to enforce the old ordinance requiring every physician in the city to register at the office of the board. The purpose of the ordinance is to make it possible for the board to find at any time if men not qualified practice or pose as physicians.

Hospital Notes.—It is generally agreed that the new hospital for the Santa Fe system is to be located at Temple.——The Alpha Sanitarium, Llano, for consumptives, has materially increased its accommodations for patients, and on August 25 it opened its new and enlarged quarters.——A sanatorium to cost $250,000 is to be erected in Shannon.

City Chemist Needed.—At a meeting of the Dallas Medical and Surgical Society, held September 8, resolutions were unanimously adopted that the society realizes the importance of the movement now being carried on by the city health officer to inspect foodstuffs offered for sale in Dallas, and urging the establishment of a department. to be in charge of a competent chemist. whose duty it shall be to examine such foods as may be brought before him, analyzing and reporting on them.

Personal.—Dr. Joseph Gilbert, Austin, physician of Travis County, has resigned to become chief medical officer at the Agricultural and Mechanical College, and assumed his duties at that institution September 8.——Dr. Herbert F. Sterzing, Austin, has been appointed physician for the city of Austin and Travis County, vice Dr. Joseph Gilbert, resigned. Later on the county commissioners appointed Dr. George S. Beaty, Sprinkle, as county physician.——Drs. Margaret Gilbert and Horace Holiday have been elected assistant physicians to the State Lunatic Asylum, Austin, vice Dr. James H. Eastland and Louis H. Kirk, resigned.

VIRGINIA.

Cocain Sellers Fined.—Richard Hunycutt and John Boush, colored. were each fined $100 and costs in the Norfolk police court September 10 on the charge of selling cocain.

Personal.—Dr. J. N. Cranshaw, Fredericksburg. has been appointed physician in the University Hospital, Charlottesville. ——Dr. Herbert O. Forbes, Jetersville, broke his arm while playing baseball September 15.

Hospital Fire.—A fire early in the morning of September 10 in Newport News General Hospital for a time threatened peril to the inmates. A panic was averted by the fire chief of Newport News, who had been operated on for hernia in the hospital a few days before, and who directed the work of the firemen.

Health Department Ordinance.—The ordinance revision commission of Norfolk will submit to the council at its meeting in October the following recommendations: That there shall be a health commissioner, who shall act as the head of the health department, at a salary of $2.500 per annum; that he shall have one assistant, who shall be head of the sanitary force of the city, and act as office man, at a salary of $1.800 per annum. and that he shall have two assistants who shall act as physicians to the city poor, at a salary of about $1,200 each per annum.

WASHINGTON.

Typhoid Fever at Camp Tacoma.—Typhoid fever is said to have been epidemic at Camp Tacoma. Up to September 4. 33 patients had been sent to the Vancouver barracks for treatment, and the same number had been treated in the field hospital.

Typhoid Fever.—An unusual number of cases of typhoid fever are in the hospitals of Spokane at present, it is said. St. Luke's Hospital has 16 cases; the Sacred Heart Hospital about 20; Washington Hospital, 10. and the Deaconess Hospital. 8. The health officer states that almost all the patients contracted the disease out of town.

Tuberculosis Society Organized.—At the meeting of the Washington State Medical Association the Washington Association for the Relief and Prevention of Tuberculosis was organized, with the following officers: President, Dr. Clarence A. Smith. Seattle; vice-presidents, Drs. Frank H. Luce, Davenport; Wilson Johnston, Colfax, and Elmer E. Heg, Seattle, and secretary. William R. M. Kellogg, Seattle.

Health of King County.—According to the report of the county health officer, Dr. Bartholomew E. Hoye, Auburn, from Dec. 1, 1904, to Sept. 1. 1906, there have been 100 cases of scarlet fever, 121 of diphtheria, 82 of typhoid fever and 22 of tuberculosis in King County outside of Seattle. Three small epidemics of scarlet fever have been reported, one from North Bend, one from Woodville and one from South Park.

WISCONSIN.

Maternity Moves.—The Milwaukee Maternity Hospital and Dispensary Association has moved into its new quarters at 424 Vliet Street.

To Build Sanatorium.—The state board of control has appointed J. E. Hoyt superintendent of construction of the Wisconsin Tuberculosis Sanatorium, to be erected at Wales, Waukesha County.

Hospital for Janesville.—The physicians of Janesville met at the office of Dr. Samuel B. Buckmaster, September 1, to consider the proposition of establishing a hospital to be operated in Janesville under the management of the Sisters of Mercy.

College Opens.—The opening exercises of the Milwaukee Medical College were held September 17. Addresses were made by the president. Dr. William H. Earles, and others. who made references to the university negotiations, the establishment of which are now pending.

Epidemic Diseases.—Bayfield is said to be experiencing an epidemic of typhoid fever. About 15 cases are reported and the disease is thought to have been caused by bad water.——In Lodi 5 cases of typhoid fever have been reported.——On account of 2 cases of diphtheria at Wauwatosa. three grades of the public schools have been closed.——Smallpox is reported to have broken out in Cambria, where 10 cases have appeared. The church conference which was to have been held in Cambria has been transferred to Portage on this account.——Smallpox is reported at McDill, where 2 cases have appeared.

Personal.—Dr. James S. O'Brien, Milwaukee, has been elected president of the board of directors of St. Mary's Hospital; Dr. George D. Ladd, vice-president. and Dr. George W. Fox. secretary.——Dr. Joseph P. McMahon. Union Grove, has sailed for Europe.——Dr. Guy C. Bowe, Fond du Lac, has discontinued practice in the state and will remove to Ashland, Va.——Dr. Thomas W. Nuzom and wife, Brodhead, have returned from Europe and will locate in Janesville.——Dr. G. Fred Colter, Marinette, has been reappointed a member of the advisory board of the State Tuberculosis Sanatorium.

GENERAL.

American Electro-Therapeutic Association.—The sixteenth annual meeting of this association was held in Philadelphia, September 18-20. under the presidency of Dr. Charles K. Mills, Philadelphia. The name of the association was changed to the Physico-Electro-Therapeutic Association. and the following officers were elected: Dr. Morris W. Brinkmann, New York City, president; Dr. J D. Gibson, New York City, and Mihran K. Kassabian, Philadelphia, vice-presidents; Dr. Albert C. Geyser, New York City, secretary, and Dr. Richard J. Nunn. Savannah, Ga., treasurer (re-elected), and Drs. William B. Snow. New York City; Fred H. Morse. Boston. and Francis B. Bishop, Washington, D. C., executive council. The association will meet in Jamestown, Va., in 1907.

Hospital Superintendents Meet.—The Association of Hospital Superintendents held its eighth annual meeting in Buffalo, September 18-21. After the meeting had been called to order by the president, George T. Ludlam, New York City. Mayor J. N. Adam welcomed the association to Buffalo. and Dr. George H. M. Rowe of the Boston City Hospital responded. In his annual address the president declared that the hospital as an institution had not kept pace with the development of the country. and that in an organization where all the hospitals in the country are bound together by common ties. would be the greatest hope in expansion. He suggested that the name of the association be changed from the "Association of Hospital Superintendents" to "The Hospital Association." in order to allow the admission to membership of managers. trustees and representatives of medical boards, in addition to superintendents. The following officers were elected: President. Dr. Renwick R. Ross. Buffalo General Hospital: vice-presidents, Superintendent Curtis, St. Luke's Hospital, Chicago; Superintendent W. W. Kenny, Victoria General Hospital, Halifax, N. S., and Dr. Alice M. Seabrook, Woman's Hospital, Philadelphia; secretary, Superintendent George J. Bailey, Jefferson Medical College, Philadelphia, and treasurer, Superintendent Asa Bacon, Presbyterian Hospital, Chicago. The next meeting of the association will be held in Chicago, Sept. 19-21, 1907.

CANADA.

School Medical Inspection in Montreal.—School inspection in Montreal has become an actual fact. Twenty-one inspectors have recently been appointed from among the medical fraternity of that city.

The consumption of Liquors and Tobacco in Canada.—During the year ending June 30, 1906, the *per capita* consumption of alcoholic liquors and tobacco in Canada was as follows: Gallons, spirits, 0.927; beer, 15.660; wine, 0.698; tobacco, pounds, 2.991. There was a decrease in the consumption of spirits and an increase in that of beer, wine and tobacco.

Medical Schools Open.—The inaugural address in connection with the opening of the Medical Faculty of McGill University was delivered September 18 by Dr. R. F. Ruttan, professor of chemistry in McGill. This is the seventy-fifth session.——The Manitoba Medical College reopened the first week in October.——The Medical Faculty of Toronto University commenced work for the session October 1.

Personal.—Sir William Broadbent, who has been in Canada for the last six weeks, has returned from a trip across the continent, and has sailed for home.——Dr. Gerin Lajole, formerly a practitioner in Montreal, but for the past six years in France, has been appointed a surgeon-major in the French army.——Dr. J. L. Robinson, Montreal, has been appointed medical superintendent of the Vancouver General Hospital.

Hospital News.—During the three months ending June 30, 1906, 881 patients were treated in the Montreal General Hospital. There were 59 deaths. In the out-door departments there were 10,893 consultations. Dr. F. J. Shepherd was elected to fill the vacancy on the committee rendered vacant through the death of Dr. Craik.——The annual report of the Toronto General Hospital for 1905 has just been issued. In it is incorporated a report of 110 cases of typhoid fever treated in the institution from Jan. 1 to Dec. 31, 1905. Seventy-four per cent. showed rose spots; the spleen was enlarged in 54 per cent. The Widal reaction was positive in 76 per cent. before the seventh day of admission. The diazo reaction was obtained in 52 per cent. of the series. Nine patients died, a percentage of 8.2. Relapses occurred in 14 cases. Lobar pneumonia occurred in 7 cases; bronchopneumonia in 1 case; pleurisy with effusion in 2; bronchitis in 12; perforation of the bowel in 2 (both treated with purgatives); phlebitis in 11; convulsions in 2.

FOREIGN.

Institute for Testing of New Drugs.—The "George Speyer House," an institution erected and endowed by the widow of a Frankfurt capitalist, was dedicated with much ceremony September 3 at Frankfurt a. M. The institution is to be under the supervision of Professor Ehrlich, and is designed for the investigation and testing of new drugs.

The Schaudinn Medal.—An endowment has been raised for the purpose of presenting a medal every two years for the most prominent works in the domain of microbiology. The medal will be known as the Fritz Schaudinn medal, and will be awarded on the anniversary of Schaudinn's death, at the Institute for Ship and Tropical Diseases, at Hamburg, the scene of Schaudinn's last labors. The medal will be awarded irrespective of nationality.

Diploma of Public Health in Australia.—The faculty of medicine of the University of Sidney, according to the *Lancet*, has recommended the adoption of by-laws and regulations for a diploma of public health which will testify to the candidate's proficiency in all branches of study, scientific and practical, necessary for the proper performance of the duties of health officer. The examination will be in two parts: (1) The general principles of sanitary science; and (2) state medicine and the applications of pathology and sanitary science to public health.

Hallucinations of Chloroform.—A Paris physician who had performed an operation under chloroform on a housemaid was accused by the latter of taking improper liberties with her mistress, as she saw while coming out from under the influence of the chloroform. The medicolegal experts, Professors Brouardel and Debove, testified that chloroform was liable to induce hallucinations, not only during the anesthesia, but even after partial awakening. The French court accepted this testimony and ruled out the housemaid's evidence in a recent divorce case.

New Sanitary Service for India.—It is reported that in view of the continuance of the epidemics of plague, cholera and smallpox in India and the heavy perennial mortality from malaria, that the government has decided to create an entirely new service whose duty it will be to safeguard public health. According to the *British Medical Journal*, Lord Kitchener is greatly concerned by the high percentage of preventable disease cases in the army and has instituted a system of lectures on sanitation, to be delivered during the cold season in every military station in India by specially selected officers of the Royal Army Medical Corps.

A "Patent Medicine" Before the German Courts.—The proprietor of a cure for baldness and the business manager of a local paper at Hanover, Germany, were recently sued for publishing extravagant claims in regard to the virtues of the remedy known as *eau de merveille*. The *Allg. med. Ct.-Ztg.* quotes an account of the proceedings to the effect that the chemical experts testified that the 50 cent bottle contained merely alcohol and water with some aromatic oils, the cost of which could be only a few pennies. The proprietor, while vaunting the efficacy of the remedy, was nonplussed by the inquiry why he had not used it on his own bald head. The two defendants were fined $5 each.

Change Desirable in Meeting Places.—There is considerable discussion just now in Germany as to the place where the annual congress of internal medicine shall be held. An effort is being made to have the members vote to have the congresses held invariably at Wiesbaden, instead of, as at present, at Wiesbaden only every second year, and the intervening years at different places. Much ink is being used to proclaim the importance and benefits of holding the congresses at various points so as to give all the physicians occasionally a chance to have the congress in their immediate neighborhood, and save them the time and money of a long journey to the meeting place, besides the other advantages of change.

Epileptic Colony in Scotland.—The Colony of Mercy for Epileptics, in connection with Quarrier's Homes at Bridge of Weir is now ready for occupancy. One house has been opened and is occupied by 12 colonists, all young men. It is proposed to fill up the houses gradually as suitable applicants are found. Only thoroughly sane young men who are capable of taking part in healthy outdoor garden and farm work will be admitted to the colony. Each colonist is expected to provide himself with clothes, and to pay a minimum sum of about $2.50 a week toward his expenses. It is not expected that the colony will be self-supporting, but as funds become available it is intended to erect buildings for women and children.

The Wanderings of a Leper in Europe.—A recent simila occurrence in the United States lends interest to the statemen in an Austrian exchange that a man of 48, in the early stage of leprosy, recently arrived at the Austrian frontier on his way to his home in Roumania. Passage through Austria was not allowed, and he was sent back, with a car to himself, the doors locked and sealed. The Bavarian railroad returned the man to the place where he had taken the train, Frankfurt a. M., where he was transferred to the city hospital and isolated. It is proposed to send him back to London, where the disease was first diagnosed and where he started on his journey. Our exchange queries in conclusion: "What country will finally have to keep him?"

Health Board Warns Against a Fake.—The local board of health at Carlsruhe, Germany, has recently published a notice in regard to an electric battery advertised by "Professor Keith-Harvey of London" in the local papers as a sure cure for deafness. It describes the absurdity of expecting that deafness can be cured by "a mild galvanic current conducted to the muscles of the ear," even if the advertised battery is all that it claims to be. It also calls attention to the printed circular letter sent out by the advertisers in reply to applicants, although they advertise "a careful individual diagnosis made from the symptoms described in each case." The notice closes by warning explicitly against the "swindle gotten up solely for the purpose of obtaining money from the credulous."

Much Radium in Vienna.—Some time ago the Vienna Academy of Sciences received by official grant 10,000 kilograms of the uranium ore from which radium is produced. It was sent to the academy from the government mines at Joachimsthal for purposes of scientific research. The radium derived from this raw material has been accumulating until now the academy has on hand pure radium to an amount worth fully a quarter of a million dollars, according to the present market value of radium. It is not to be sold, but will be distributed among scientific bodies for purposes of research. The Austrian authorities have decided to erect a special laboratory at

Joachimsthal for the production of radium salts on the spot. As recently already mentioned by our Vienna correspondent, a health resort is to be opened there to take advantage of the radium emanations in the waters.

Behring's Tulase.—The first report on the treatment of patients with tulase has just been published in the organ of the International Antituberculosis Association, *Tuberculosis.* The remedy is, for the present, given only to a few clinics which have sent one of their assistant physicians to Behring's institute at Marburg to take a three months' course in preparatory training in the use of the remedy, and have agreed to keep records according to a prescribed system. The experiences to date have demonstrated that the tulase can be administered subcutaneously, intravenously or by the mouth. It is given to infants in milk. It is not claimed to be a remedy that will cure already existent tuberculous processes, but it is said that administered to the young, it will prevent the development of tuberculosis, and will act on an existent tuberculous process in such a way that the natural tendency of the lesion to heal will not be interfered with by renewed tuberculous infection. The tulase is given in minute doses, and for diagnostic purposes can be substituted for tuberculin. Behring's first announcement in regard to his tulase was mentioned in these columns on page 869.

How They Humbug the Dear People in Italy.—A correspondent, Dr. F. E. Sondern, New York, writes from Geneva, Switzerland: "While in a small Italian town some days ago, the enclosed circular was being distributed." The circular is in Italian and reads:

> A free visit will be made by one of the 20 professors of the American Medical Association residing in Milan, on August 25, at Verbano Restaurant, from 8 till 2 p. m., at Stresa. These professors cure by the homeopathic method, acknowledged to-day to be the best for the cure of all diseases, especially the most obstinate, chronic cases. The remedies used for the cure of these acute and chronic diseases are imported directly from the United States of America and from Germany, and are sent out by our house in Milan, in conformity with the law of the realm. With this new scientific system of treatment, thousands of cures have already been obtained in Italy in acute and chronic diseases, many of them declared incurable by renowned professors in Italy, and with little expense, as we can prove by the thousands of letters from grateful patients, which we will take pleasure in showing to whoever will apply at this office.

Then follow names and testimonials of some among the alleged 4,320 patients that have been cured. The circular is signed, "American Medical Association, Milan-Palazza, Genova 3, Milan."

Relief of Australian Dependent Children.—The report of the State Children Relief Board of New South Wales for the year ending April 5, 1906, shows 7,036 children dependent on the state, being about 0.5 per cent. of the population. Of these a little over one-half are placed in homes apart from their mothers, with an average of three children to two guardians. This secures, as far as possible, the individual attention of the foster mother. The maximum number of children in a home is fixed at three, except under peculiar circumstances. The care of the children is supervised by visitors, both salaried and voluntary, in such a way that each child receives a visit on the average twice a year. Cottage homes having the average capacity of twenty are provided for invalid children who are not sick enough to be placed in a hospital, but need special nursing and attention. These homes are under the charge of experienced women, who act as nurses under medical supervision. Deserted wives and widows are allowed to board their own children under supervision. Statistics show that while the aggregate of the women is now decreasing each year, the proportion of deserted wives to widows is steadily increasing. Older children are apprenticed, the board collecting their wages and depositing them to a fund out of which the children are paid their share partly on completion of the indentures and the balance when the child has reached the age of 21 years. The board considered it necessary to oppose the proposition of a milk wagon drivers' association to deliver milk but once a day on holidays, on account of possible injury to the health of children, and was successful in defeating the proposed action.

LONDON LETTER.

(From Our Regular Correspondent.)

London, Sept. 8, 1906.

The Milk Supply.

The problem of a pure milk supply greatly exercises those interested in public health. Under existing conditions there is undoubtedly gross neglect of sanitary precautions and cleanliness. The much advertised precautions such as washing hands and udders are seldom carried out, and the milk is polluted with cow dung and other dirt. "If canned meat has killed its thousands, milk has killed its tens of thousands," declares a health officer. It is computed that there are over 4,000,000 milch cows in the United Kingdom, and that the average yield of milk per cow per annum is 420 gallons. Thus the total yield is about 1,700,000,000 gallons. As milk is sold for fourpence a quart, the total cost per annum amounts to about $570,000,000. In only a minority of cases are the conditions of this enormous industry above suspicion. The question of transit also presents difficulties. Almost all the milk consumed in London comes from such distances that it is from 12 to 24 hours old before it is delivered. The milk taken from cows at 4 a. m. arrives only in time for the afternoon delivery, when only half of it is required. The remainder is kept by the dairyman to be mixed with the afternoon supply for delivery next morning. Thus the morning supply is a mixture of milk more than 12 hours old with milk more than 24 hours old. But something still worse may happen. The fact that a cow gives a richer milk in the smaller afternoon milking than in the larger morning milking leads unscrupulous dealers to mix separated milk with the richer article. This can be seen going on almost any day at the large railway stations. When the supply is larger than is required the surplus is allowed to remain at the station, to be manipulated day by day with further supplies until it can be advantageously disposed of—perhaps three or four days after milking. Acting on the recommendation of the public health committee, the progressive London County Council has determined to seek in the next session of parliament several important powers for dealing with matters of sanitation and public health. The most important relate to the supervision and regulation of the milk supply of London. Power will be asked to enable the council to prohibit the supply of milk from a dairy if the health officer is of the opinion that infectious disease is caused or likely to be caused by the consumption of such milk. To enable necessary supervision to be carried out the council seeks power to require dairymen to supply lists of their customers and the sources from which their milk supply is obtained, and power to impose penalties for selling milk from tuberculous udders. It is also proposed to compel dairymen to report cases or suspected cases of tuberculosis of the udder and to isolate cows suffering from this disease. Power is sought to enable the council to take samples of milk arriving at any railway station in London and elsewhere and to deal with milk which is found unfit for consumption. With regard to milk for infants, the council intends to seek authority to enable the various local metropolitan borough councils to provide and to sell milk for the food of infants. This has been done with good results as to infant mortality by some local councils, but the expenditure is illegal.

Medical Education in London.

The high standard demanded by the University of London for the degree of doctor of medicine causes only a small minority of the London students to seek to obtain it. The majority content themselves with obtaining a license from the College of Physicians and Surgeons. This is sufficient for the purpose of practicing, but the licensee is not strictly entitled to the title of doctor, though it is freely given to him by the lower and lower middle classes. Among the upper and educated classes he is termed "Mr." and is under some disadvantage as compared with those who have obtained the degree of doctor of medicine from a university, and who are correctly styled "doctor." This degree is much more easily obtained in the provincial, Scotch and Irish universities than in London. Consequently there is a tendency of students to flock to the latter to the neglect of the London schools, and yet the London hospitals provide opportunities for the study of clinical medicine which are unequaled in the British Isles. The subject is discussed by the *Lancet* in its annual address to students. Last year the number of students at the London medical schools was rapidly dwindling. "By so much," says the *Lancet*, "as the work done in the wards and out-patient departments of the London hospitals is not utilized for educational purposes is our country placed at a disadvantage compared to others—we are wasting our opportunities."

The Study of French and German for Medical Students.

Professor Osler has issued the following memorandum to the Oxford undergraduates regarding the importance of the study of French and German: "During your undergraduate days you should become familiar with the French and German languages. To do this one of the best ways is to read small French and German text-books, of which (with the advice of colleagues) I enclose a list. Half an hour a day will soon give you the necessary facility in translation. Later in your course get into the habit of reading, in the Radcliffe Library, a French and a German periodical. You will in this way become familiar with foreign literature, which has ever been deemed a necessary equipment of a cultivated physician." The following list of French and German books is recommended to undergraduates taking science courses preliminary to medicine, and to students of anatomy and physiology. French—Aubert: "Phénomènes de la Vie." Ditte: "Premières Notions de la Chimie." Joubert: "Traité d'Electricité." Meric: "Dictionnaire des Termes de Médecine Franç.-Anglais." German—Born: "Compendium der Anatomie des Menschen." Reynolds: "Leitfaden zur Einführung in die Experimental-Chemie." Fiedler and Sandbach: "A First German Course for Science Students." Osbonne: "German Grammar for Science Students." Schenk und Gurber: "Leitfaden der Physiologie des Menschen." Lang and Abrahams: "German-English Dictionary of Terms Used in Medicine and the Allied Sciences."

Central Emergency Fund of the British Medical Association.

The British Medical Association has for some time been engaged in combating the evils of contract practice. Many clubs take advantage of the severe competition which prevails in the profession to pay exceedingly inadequate fees to their medical officers or, in the language of the trade unions, to "sweat" them. No matter how low the remuneration, the clubs have usually been able to obtain a physician to fill a vacancy caused by dissatisfaction of the previous holder of the appointment. The British Medical Association, however, has put a check on this unlimited competition by arranging concerted action of the profession. The local branches determine whether the conditions of an appointment are satisfactory and if not, endeavor to prevent any physician from taking it. In the advertisement pages of the *British Medical Journal* warning notices are inserted asking physicians not to apply for any appointment without first communicating with an officer of the association, whose name is supplied. At the places mentioned some dispute is in progress, usually in connection with some form of medical contract work. Any physician who thinks of applying for the vacancy is put in possession of the facts. The current number of the *British Medical Journal* contains as many as 19 such notices. The association has now gone a step farther. Last year the central council passed a resolution providing that a central emergency fund for dealing with disputes in case of contract practice and otherwise, under the management of the medico-political committee, be created by voluntary subscription. The following scheme of the fund has now been prepared: 1. The fund is created by voluntary subscription to assist members of the profession in various parts of the country in maintaining the interests of the profession against organized bodies of the community. 2. All members of the profession are invited to contribute. Any contribution may be marked for use in specified disputes, or for application to special methods of carrying on the objects of the fund, and when not so marked shall be deemed to be given for disposal at the discretion of the medico-political committee. 3. The fund may be applied as follows: (a) By a grant or grants to any individual practitioner to assist him in maintaining any position in which the association shall have decided to support him or to compensate him for losses which he shall have incurred through taking action approved by the association. (b) By a grant or grants to any division or branch of the British Medical Association, for its assistance in defraying expenses incident to the conduct of local disputes falling within the scope of the objects of the fund. (c) By expenditure under direct supervision of the medico-political committee for any action which the committee may deem necessary or advisable for the promotion of the general objects of the fund.

LONDON, Sept. 15, 1906.

First Report of the Expedition to the Amazon of the Liverpool School of Tropical Medicine.

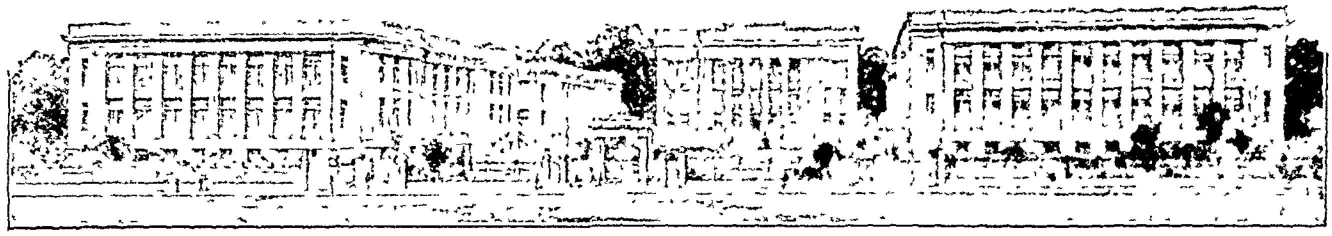
This expedition left its headquarters at Manaos, Brazil, and proceeded up the River Amazon for the purpose of invesigating the distribution of disease and of yellow fever in particular. Iquitos in Peru was reached on Dec. 31, 1905. A stay of three months was made there and a report was presented to the Peruvian government. Iquitos lies along a high bank overlooking the river Maranon and behind it are swamps. The roads are in a wretched state—undrained, full of ruts and holes—and in wet weather become almost impassable. The town, especially along the river bank and near the swamps, is noted for the number of mosquitoes. Houses near the river are never free from them and unless wire screens are used the situation becomes intolerable after dusk. Neither water reservoirs nor privies are protected from mosquitoes; stegomyia and culex were frequently found breeding in both. As is usual, stegomyia was found to breed freely in the various discarded pots and pans, bottles and barrels wh accumulate in tropical establishments. The sanitary cond tion of the town is very bad. Drains for the most part a mere trenches cut in the sandy soil. There is no public wate supply; water is obtained from springs or from cisterns sunk in the ground in which rain water is stored. There is no proper system of sewage disposal. The poorer classes defecate indiscriminately in every part of the town, and fecal contamination of drinking water is common. *B. coli communis* and eggs of *Ankylostoma duodenale* were frequently found in the water. There is no system of garbage disposal; household refuse is deposited almost anywhere. Notwithstanding its insanitary condition, Iquitos is not exceptionally unhealthy. The prevailing diseases from January to March are whooping-cough, measles, bronchitis and infantile diarrhea among children; gastritis, gastroenteritis, bronchitis and malaria among adults. Other diseases seen were leprosy, amebic dysentery and tuberculosis. The expedition had hoped to see "*vomito negro*," which is locally considered to be distinct from yellow fever, but no cases of either occurred. From the information given by the local physicians they appeared to be the same disease. To ascertain the prevalence of malaria in the blood of the general population, 764 persons were examined. In 98 the malignant tertian parasite was found. The majority of those infected were Indians and men employed in launches along the rivers. Of 97 children between the ages of 4 and 14, only 2 were infected. The hemoglobin showed a low average in Indians and the poorer classes, varying between 45 and 72 per cent., and in the better classes between 72 and 80 per cent. The explanation of this marked anemia is believed to be ankylostomiasis. Practically all the native children are infested with the parasite. An accompanying infection with ascaris lumbricoides or various teniæ was frequently observed. Among the domestic animals at Iquitos the following diseases were observed: In cattle piroplasmosis, malignant edema and perhaps quarter evil; in swine trichinosis; in poultry chicken cholera and fowl diphtheria; and in rats *Trypanosoma lewisi*.

Glycerinated Calf Lymph.

A preliminary report has been made to the local government board by Drs. F. R. Blaxall and H. S. Fremlin on experiments undertaken to determine whether or not the active agent of vaccine lymph could withstand, without loss of potency, temperatures below freezing point. Afterward the doctors were directed to ascertain whether sustained subjection of glycerinated calf lymph to a temperature of 5 degrees (C.) below freezing point could be used to maintain a reserve of lymph without loss of activity. General experience and numerous experiments have shown that the agents most productive of weakness and failure in glycerinated lymph are age and heat. Thus crude lymph loses its potency if subjected for five minutes to a higher temperature than 57.5 C. Glycerinated lymph becomes inert if kept at 37 C. for more than thirty-six hours. It was anticipated that if the everyday deleterious influence of heat on lymph could be prevented the loss of activity which is associated with age could be diminished and a method of storage attained. Experiments were commenced in January, 1900. The lymph was exposed to various low temperatures, including that of liquid air (—180 C.). The following conclusions were reached: 1. Glycerinated calf lymph can survive a temperature of 180 C. below freezing point for a considerable time without loss of potency. 2. It can be retained in a cold store at —5 C. for a year without diminution of potency, whereas stored for the same time at 10 C. it loses activity to a considerable extent. 3. Sustained subjection to cold appears not to be injurious.

The Overlying of Infants.

The overlying of infants is the cause of more than 1,600 deaths annually. A meeting has taken place between six members of the National Society for the Prevention of Cruelty to Children, three representatives of the Coroner's Society and three members of the British Medical Association. The subject was thoroughly discussed, and it was decided to take some step toward amending the act for the "Prevention of Cruelty to Children." The form of the amending bill and the steps to be taken to insure its acceptance by the legislature were left for settlement at a later date. It seems probable, however, from what passed at the meeting, that the death from suffocation of a child under the age of 3 years as a consequence of its sleeping in the bed of its parents or other adults, as also the death of a child under the age of 10 years from burning or scalding from being allowed access to an unprotected and lighted open fireplace, *ipso facto*, will be made evidence of neglect in the sense in which the term i used in the act mentioned.



THE HARVARD DEDICATION.

New Buildings of Harvard Medical School Dedicated September 25-26.

The ceremonies attending the formal opening of the new medical laboratories of Harvard University, which were described in THE JOURNAL, July 7, page 50, have more than a local interest. They mark the completion of an important step in the development of a scheme in medical education and instruction not hitherto attempted in this country. The Harvard faculty believes that a medical school should be something more than a place of instruction. It believes that the student in medicine should be so trained and drilled in research methods that it becomes the basis of all his work. This view is strongly reflected in the magnificent buildings just dedicated. In these four great laboratories every facility has been provided for instruction, training and drilling of each student individually, both as to the essentials of past research, as well as in the methods by which those fundamentals were acquired. While the laboratory methods are emphasized strongly in this celebration, they are but the nuclei about which hospitals are to be grouped at no very distant date. Boston offers annually a hospital clinic of over 15,000 ward patients and more than 130,000 ambulatory patients. In the care of this great number of afflicted persons the Harvard medical faculty has almost unrestricted facilities for studying and demonstrating disease in its various forms.

A Medical University.

In order that the greatest amount of advantage possible to suffering humanity, as well as to medical science and instruction may result from a closer union of the laboratory and the hospital clinic, these new laboratories are to be an integral part of a great hospital teaching medical center—a medical university. The hospital of the Good Samaritan is already established on the site, and the remaining fifteen acres are to be used for the Harvard Dental School, an infant's hospital, children's hospital and a large general hospital, all to be under the jurisdiction of the corporation of Harvard University. The whole plant is to form a part of a general architectural scheme, of which the Fenway is the center. To meet this design the administration building and the four laboratories face a quadrangle 215 feet wide and 480 feet long, which is the continuation of a proposed boulevard extending to the Fenway.

Plan and Construction of Buildings.

All these buildings are of white marble, and are designed in a simple, classic style, an adaptation from the Greek. The administration building, facing the open court, is raised on a high terrace, which gives a setting pleasing and majestic. The approach is by means of a broad flight of steps from the terrace to the front portico of the building, from which rise six ionic marble columns, each over fifty feet high. The interior of this building, on the ground floor, is treated with marble floors and wainscoting and columns, etc., in keeping with the general design of the exterior. The right wing of this floor is arranged for the administrative offices of the school, the faculty room, committee rooms, and others. The left wing contains rooms for students and alumni, a reading room, and a smoking room. Over the students' room is an amphitheater, with entrance so arranged that the students enter from the second floor to the upper tier of seats, while the lecturer with his lecture material, is admitted from an intermediate floor below. This lower floor has a connected preparation room, to which the elevator runs from the receiving room and museum, so that specimens may be transported directly on movable tables. The seats in this amphitheater, as in all the other class rooms, are especially designed with movable seats and writing tablets. Every facility is provided for illustrating by means of lantern projections. The remaining portion of the second floor in this building is divided into class rooms

The Warren Museum.

The Warren Museum occupies the entire upper portion of the building, and has a total floor area of over 22,000 square feet. The museum is equipped with dust-proof cases and has every modern museum appliance. The curator's room and receiving room are equipped for laboratory work and have elevator connections with the receiving room in the basement. In the basement are located x-ray rooms, students' lockers, rooms for instruction in bandaging, and a receiving room for museum specimens. The locker room is extended on both sides into a wide corridor which runs underneath the terrace facing each laboratory, thus forming a covered passage between the four laboratories and the administration building.

The four laboratories are so arranged that those most closely affiliated with each other are in the same building. These buildings are located as follows: On entering the court from Longwood Avenue the first building on the right is the hygiene and pharmacology building; the other building on the right is the physiology and chemistry laboratory. On the opposite side of the court the building nearest Longwood Avenue is for pathology and bacteriology, while the one for anatomy and histology is next to the administration building. In the rear of the pathologic and bacteriologic building and separated from the main laboratory, is a building for animals, with accommodations for all kinds and sizes, from cows and sheep to birds and guinea-pigs. The power house is situated some distance in the rear of the hygiene-physiology pair of buildings and at the best advantage for furnishing heat, light, electricity, refrigeration and compressed air to the several laboratory buildings, and also to the adjacent hospitals now built and to be built in the future. Provisions are made for increasing the size of this power plant so as to provide for future hospitals and other buildings, as well as the enlargement of the present laboratories.

Construction of Laboratories.

The construction of the laboratories is unique and original. They are constructed on a plan devised and amplified by Prof. William T. Porter and Prof. Charles S. Minot of the Harvard Medical School. This plan consists of an aggregation of "units," and is briefly as follows: The outside walls are built with piers 4 feet each and the windows between are 6 feet wide and extend to the ceiling to provide proper lighting, the whole making a unit of 10 feet. The outside and corridor walls and the floors are the fixed portions ot the buildings, the corridor walls being hollow to contain the heating and ventilating flues. Running through each wing is a central corridor, from which the laboratories lead. The unit room is roughly, 23 feet deep by 10 feet long, the window coming in the middle of the ten-foot exterior wall space. The partitions opposite each unit pier are composed of terra cotta, which can be easily removed or supplied, making a room 23 by 20 feet, or any multiple of 10 feet, thus providing for rooms suitable for small sections, laboratories, private research or for the professors' or instructors' personal use. As the growth of the school necessitates, each wing can be lengthened by additional piers and windows, and when extended to a distance of 216 feet may be connected together in rear, enclosing a court 112 feet long by 70 feet wide. This trebles the capacity of each laboratory without interfering with light or architectural design. The buildings are divided into stories to conform to the needs for which they are intended. In the large laboratories for general students' use the stories are high and the windows are carried to the ceiling, thus affording abundant light to all parts of the room, sufficient for microscopic work.

For smaller rooms used for individual research work intermediate or "mezzanine stories" are introduced. In the center of each building is an amphitheater occupying two stories, and in the second story of each is a library. These are accessible from both wings. Each amphitheater has a seating capacity of 265, and completed facilities for lantern projections, etc. Each laboratory building is equipped with every facility for carrying on the work of that special department, e. g., the anatomy and histology building has its separate driveway for introducing anatomic subjects, large refrigerator for storage, isolated dissecting rooms, and an elevator so located as to properly serve the dissecting and demonstrating rooms; the physiology and chemistry building its pens, cages, exercise yards, etc., for animals on the roof, while each department conducting operations on animals has its animal operating suite, equipped with most approved hospital appliances; the chemistry wing is constructed with special reference to the varied methods of research and investigation now attracting the attention of scientists; in the bacteriologic and pathologic building four large students' laboratories occupy one wing, while the south wing is divided into mezzanine stories for research work.

The rear end of one basement is devoted to photography. In the hygiene and pharmacology building a completed museum of food products, models of appliances relating to the public health, etc., are given a special section. Comparative pathology forms a separate and distinct department in this building.

The acoustic properties and seating arrangements of the various amphitheaters and laboratories have been carefully supervised by Professor Sabine of Harvard University.

Dedicatory Exercises.

The formal dedicatory exercises were held at the new buildings on Longwood Avenue, Boston, September 25 at 2 p. m. Grouped about President Eliot on the portico and terrace of the administration building were gathered an assemblage of eminent and distinguished scientists and notable persons, while the large gathering ot alumni and lay persons on the lawn in front testified to the intense interest felt in this great event. Besides the president and fellows and overseers of Harvard University and the medical faculty, some of those occupying seats on the platform were Governor Guild, Russian Ambassador Rosen, Mr. J. Pierpont Morgan, Mr. Charles H. Tweed, Most Rev. W. H. O'Connell, D.D., Boston; Prof. W. H. Welch, Johns Hopkins University; Prof. William Keen, Philadelphia; Prof. A. Jacobi, New York; Sir Thomas Barlow, London; Dr. William Ewart, London; Prof. Franz Keibel, Freiburg; Prof. John Glaister, Glasgow; Professor Durfour, Lausanne; Prof. C. S. Sherrington, Liverpool; Prof. Ramos Mexico; Prof. R. A. Reeve, Toronto; Sir William Hingston, Montreal; Prof. R. F. Leith, Birmingham, England; Prof. G. S. Woodhead, Cambridge, England; Prof. Harvey Littlejohn, Edinburgh; Prof. S. C. Minot, representing Royal Institute, Florence, Italy, and representatives of every university and medical school in America, as well as from many American and foreign scientific bodies.

Program.

The exercises consisted of prayer, George Angier Gordon, D.D. Address, "The Enlarged Foundation," J. Collins Warren, (Hon.) Moseley Professor of Surgery. "The Buildings," Charles A. Coolidge, representing the architects. "Acceptance of the Buildings," the President of the University. "The Faculty of Medicine," the Dean. "The Laboratories," Thomas Dwight, Parkman Professor of Anatomy. "The Clinics.' Frederick C. Shattuck, Jackson Professor Clinical Medicine. Dedication of the Buildings, the President of the University. Benediction. Demonstration of the buildings.

The Enlarged Foundation.

Dr. John Collins Warren spoke as follows:

It is my duty and privilege to announce to you on this occasion the completion of the great undertaking in which the faculty of medicine has been engaged during the past five years.

The first great step toward the foundation of a medical university has been accomplished. The laboratories for teaching and research are about to be opened on a scale far beyond what has been attempted before, and this great machine, with all its vast resources, is to be made an agent not only for the diffusion of learning, but for substantial aid and comfort to the suffering in the numerous hospitals by which it is soon to be surrounded.

But these noble buildings speak not only for a new era in medical teaching and medical research, but also for the interest which has been aroused in its behalf by men and women of public spirit.

How could a more appropriate and enduring monument to illustrious dead be raised than such as these?

This group of three buildings, with classic outline, a fitting memorial to a noble Junius, one whom we are proud to remember as a former citizen of Boston, is to-day dedicated to science by the princely liberality of a son—Filius patre dignus—whose benefactions are a household word wherever science and the fine arts are held in high esteem.

Nearby stands a memorial to one of the pioneers who have opened a pathway for the commercial world to the treasures of our great west, a monument made possible by a lady bountiful, whose devotion to the memory of her husband has been illustrated in many a worthy cause.

But it should not be forgotten that one building is the gift of a citizen of Boston, and is to bear an honored Boston name, a name which stands for all that that implies; and we shall ever gratefully recall the innumerable gifts of the grand army of Bostonians who are, and always have been, ready with generous aid.

Last, but not least, we must remember to-day the good deed of one who studied with intelligent care this great educational problem and by generous endowment made it a living reality.

To you benefactors, all I stand here to-day, in behalf of my colleagues, to say that from the bottom of our hearts we thank you, and that we appreciate what you have done for us, and we would pray for good will and sympathy from you in our work, for does not the Scripture tell us that "where thy treasure is there will thy heart be also"?

Dedication by President Eliot.

President Eliot's dedication of the buildings was as follows:

I DEVOTE THESE BUILDINGS AND THEIR SUCCESSORS IN COMING TIME TO THE TEACHING OF THE MEDICAL AND SURGICAL ARTS, WHICH COMBAT DISEASE AND DEATH, ALLEVIATE INJURIES, AND DEFEND AND ASSURE PRIVATE AND PUBLIC HEALTH, AND TO THE PURSUIT OF THE BIOLOGIC AND MEDICAL SCIENCES ON WHICH DEPENDS ALL PROGRESS IN THE MEDICAL AND SURGICAL ARTS AND IN PREVENTIVE MEDICINE. I SOLEMNLY DEDICATE THEM TO THE SERVICE OF INDIVIDUAL MEN, AND OF HUMAN SOCIETY, AND INVOKE ON THEM THE FAVOR OF MEN AND THE BLESSING OF GOD.

In accepting the buildings President Eliot said that the buildings and the permanent funds accompanying them was the largest single addition to the university since 1650. He further said:

The president and fellows well understand to whom they are indebted for this great gift. It is due in the first place to the constructive imagination and indomitable zeal of a few of the university's teachers of medicine; secondly, to the discerning and liberal acceptance by a very few rich men and women of veritable opportunity to do some lasting and pervasive good, with no admixture of evil, and with high promise of prompt beneficent results, a promise firmly based on the rapid progress of medical science within the past thirty years; thirdly, to the accumulated influence in favor of the medical profession which has been exerted in Boston and its vicinity for more than 100 years by a series of much-respected medical personages and strong medical families; and lastly, to the habit of contributing to public objects from private means, clearly manifested by the first settlers on Massachusetts Bay, and maintained and amplified by the best part of the community in every generation since, as the people rose from poverty to comfort and through a diffused well-being to occasional private affluence and public magnificence.

These superb buildings, therefore, are an expression of the intelligence and public spirit of many generations, and of the ardent hopes of the present generation for a new relief of man's estate.

The Medical Faculty.

Dean William L. Richardson spoke briefly on the growth and development of the school during its twenty-three years in the Boylston Street building. Continuing he said:

In these new buildings all that one could ask for has been pr vided, both for medical education and for scientific investigati and research. Here we have, as the president of the universit stated on another occasion, "the means for a new start for medic education and research in our country."

The facilities are so ample and the equipment so complete th the faculty has decided to make a new departure and to open a courses, including laboratory courses, to persons not candidate for the degree of doctor of medicine, but to special students i other departments of the university.

In taking possession of these new buildings the faculty feels a great responsibility, and can only express the hope that the future history of the school will show that the faculty has been faithful to the trust this day committed to it.

Laboratory Opportunities.

Prof. Thomas Dwight, in speaking for the laboratory, said in part:

One of the most striking phenomena of medical education during the past thirty years has been the gradual, unconscious, progressive self-arrangement of the various studies into two grand groups, that of the laboratory and that of the clinical departments. The former are in the main preparatory to the latter, in which the patient is the central figure. Sometimes the former are spoken of as the scientific courses; but this is a usage against which I protest. It is a reflection on the clinical courses, for all study and instruction should be scientific. On the other hand, the word "scientific" may suggest that the laboratory courses are not practical. This would be to say that they are taught under a misapprehension of the primary purpose of a medical school, which is to train students to practice medicine on their fellow-beings. But, and here is the heart of the matter, there is a sharp distinction between courses which are essential to a degree, and those which are not.

But this pronounced separation of the departments into these groups implies no opposition between them. On the contrary, I see everywhere the laboratory departments adding more and more copiously to the knowledge directly applicable to the welfare of our neighbors. If I mistake not, a new era has begun which already has given an earnest of what science can do for humanity, and which in the future will gain results beyond our hopes.

Clinical Facilities.

Dr. Frederick C. Shattuck, in speaking for the clinics, traced the course of study offered in medical schools and emphasized the fact that the laboratories represented only half of the undergraduate study. Continuing he said:

The paramount fact to which I beg to call your attention is that you see about you only a portion—I think I can safely say the subordinate portion—of the necessary means for furthering pro gressive medicine You see provision for the foundations of medical study and for such research into the nature of the disease as can be adequately carried on outside of, more or less apart from, a hospital which is as truly a laboratory as any one of this group of buildings.

The two great and many of the lesser hospitals of the city are within easy access We have good reason to hope that within a few years a new and largely endowed general hospital will be in operation at our very doors, in full coöperation with the university in the promotion of the highest aims of medicine

I do not know a medical school in the country which at present enjoys such clinical advantages as does the Harvard school. On the continent of Europe hospitals and medical schools are practically parts of the state and are supported by it. In this country the two grow up independent of one another, for reasons which, however interesting they are, we can not here consider. Their separation has been and is still a bar to progress in this country.

The keen American intelligence of those responsible for hospital management is rapidly recognizing the indisputable fact that the humanitarian and the educational duties of the hospital do not conflict—that they are indissolubly bound together if, indeed, they are not identical. The patients under the charge of a teacher of medicine, surrounded by sharp eyed and critical young men, are sure to receive more careful study than patients not so guarded That sick man is fortunate whose doctor, while caring for him, cares also for the advance knowledge in medicine in the largest sense

After the dedicatory exercises demonstrations were given in the various laboratories, and light refreshments were served from booths erected on the terraces. Music was furnished during the exercises by a specially trained alumni chorus.

In the evening the officers of the Alumni Association tendered an informal reception at the Boston Medical Library to the alumni and invited guests and delegates.

Academic Session.

This part of the celebration was held at Sanders Theater, Cambridge, September 26 at 11 a. m., and took the form of commencement exercises. The following program was carried out:

Sheriff Fairbairn called the assemblage to order. Rev. Edward C Moore offered prayer. Then followed the hymn, "Here Discovered are Foundations" by Grieg, sung by the large alumni chorus, which later was heard in the specially composed number by Professor Converse, "Laudate Dominum;" "Great is Jehovah" by Schubert-Liszt, and the Harvard hymn, sung by chorus and audience. The literary portion of the exercises consisted of addresses by President Eliot and Professor Welch, the presentation of the roll of delegates by Dr. Harold C. Ernst and the conferring of degrees.

The scene at the theater was one of the most brilliant ever witnessed there, the many colored academic costumes of the visitors and the almost universal gowning of the Harvard men giving the occasion an academic touch unique at medical school exercises. The spontaneous and tumultuous ovation given Dr. Warren and Dr. Bowditch when President Eliot announced the names of the recipients of honorary degrees, was one of the most marked tributes ever paid by a Harvard audience to a Harvard man. Later, when Professor Welch acknowledged the obligation which the medical profession owes to President Eliot, the audience broke forth in applause which lasted many minutes.

The Future of Medicine.

President Eliot said in part:

The future occupations and interests of the medical profession are to be in some respects different from those of the past, and they are to be more various The ordinary physician has for the last 100 years been almost exclusively a man devoted to the treatment of diseases already developed in human bodies or of injuries already incurred.

The progress of what we call civilization exposes human beings more and more to the ravages of disease. When savages come in contact with men called civilized, they invariably suffer from diseases new to them When a rural population crowds into cities, it falls a victim to diseases from which in the country it had been exempt When hundreds of thousands of people huddle into small areas, and create there smoke, dust and noise, they suffer not only from new diseases, but from the exacerbation of diseases, not wholly unknown to them in the rural condition

If civilized society is to endure under its new exposures and dangers it is clear that the medical profession must take up with more ardor the work of preventing approaching disease in addition to the work of treating diseases arrived The profession must recognize that health is eminently a social product, just as the psychologists have recognized that the mind of a civilized man is a social product

Thus thousands of physicians all over our southern states must for years be teaching the people how to protect themselves from yellow fever Maj Walter Reed and his colleagues proved how yellow fever is communicated and—what was equally important—how it is not communicated; but thousands of medical men must see to it that intelligent application is made of that precious knowledge

Recent events have brought into strong light a new function of the medical profession which is sure to be amplified and made more effective in the near future I mean the function of teaching the whole population how diseases are caused and communicated, and what are the corresponding means of prevention. The recent campaign against tuberculosis is a good illustration of this new function of the profession. To discharge it well requires in medical men the power of interesting exposition, with telling illustration and moving exhortation.

Obviously, the function calls for disinterestedness and public spirit on the part of the profession; but to this call it is certain that the profession will respond. It also calls for some new ad justments and new functions in medical schools, which should hereafter be careful to provide means of popular exposition con cerning water supplies, foods, drinks, drugs, the parasitic causes or consequences of disease in men, plants and animals, and the modes of communication of all communicable diseases.

Medical museums should be arranged in part for the instruction of the public, and with some suitable reservations should be statedly open to the public. The medical schools should also habit ually provide popular lectures on medical subjects, and these lec tures should be given without charge on days and at hours when working people can attend In other words, selected physicians should become public preachers, as well as private practitioners America has much to learn from Europe in regard to this public-spirited service on the part of the profession.

The University of Medical Sciences.

Dr. William Henry Welch of Johns Hopkins University said:

To have recognized fully from the beginning of his administra tion the importance of this vitalizing union of the medical school with the university, to have striven patiently with full grasp of the problems and with intelligent sympathy with the needs of medicine for the uplifting of the standards of medical education, and, with the aid of his medical colleagues, to have planted these standards where they now are in the Harvard medical school, is not the least of the many enduring services which President Eliot has ren dered to American education, and, in behalf of our profession, I wish to make to you, sir, on this occasion, grateful acknowledgement of this great and beneficent work.

During the last two decades we have witnessed in this country the extraordinary rise of practical laboratory instruction from the weakest to the strongest and best organized part of our medical curriculum of our better schools. Our laboratory courses are, I believe, in several instances more elaborate and occupy more time than corresponding ones in most foreign universities.

It is, however, in my judgment, an error to suppose that from the point of view of science any fundamental distinction exists between the clinical and so called laboratory subjects other than that based on differences in the subject-matter of study. The problems of the living patient are just as capable of study by sci entific methods and in the scientific spirit and they pertain to independent branches of medical science just as truly as those of anatomy, physiology or the other so called laboratory subjects. All of the medical sciences are interdependent, but each has its own problems and methods, and each is most fruitfully cultivated for its own sake by those specially trained for the work.

There is a highly significant and hopeful scientific movement in internal medicine and surgery to-day characterized by the establishment of laboratories for clinical research, by the application of refined physical, chemical and biologic methods to the problems of diagnosis and therapy, and by the scientific investigation along broad lines of the special problems furnished by the living patient

The most urgent need in the medical education at the present time in this country I believe to be the organization of our clinics both for teaching and for research in the spirit of this modern movement and with provision for an intimate, personal contact of the student with the subject of study as he finds in the laboratory

In addition to the undergraduate instruction, our laboratories at present furnish better opportunities for the prolonged, advanced training of those intending to make their careers in anatomy, physiology, pathology and other sciences, than are afforded by most of our hospitals to those who aim at the higher careers in medicine and surgery. A further disadvantage is that while the former class, after good, scientific work may reasonably look forward to desirable positions as teachers and directors of laboratories, the latter, however high their attainments, in consequence of the separation of the medical school from any control over the ap pointments to the hospital staff, can not anticipate with any de gree of assurance similar promotion in their chosen lines of work, and consequently the medical faculty has not so wide a field of choice in filling the clinical chairs as in filling those of the auxiliary sciences

The removal of these deficiencies on the clinical side of medical education in America requires some reorganization of its staff on the part of the hospital, or at least its voice in appointments to the hospital staff. So far as our resources permit, we have, I think, accomplished this reform at the Johns Hopkins Medical School and Hospital. The welfare of the patient is the first obligation of the trustees of the hospitals and of physicians in attendance, but nothing is more certain than that cordial coöperation between medical school and hospital best subserves the promotion of this welfare Fortunate the hospital and fortunate the patients brought into such relations with the Harvard medical school

Award of Honorary Degrees.

President Eliot awarded the honorary degrees as follows· •

Honorary Doctor of Arts.—Charles Allerton Coolidge, architect, designer of the buildings.

Honorary Doctor of Science.—Dr. Simon Flexner, New York.

Doctors of Laws.—Dr. John Collins Warren, Boston; Dr. Henry Pickering Bowditch, Boston; Dr. Jose Ramos, Mexico; Dr. Franz Keibel, Freiburg, Germany; Dr. Charles Scott Sherrington, Liverpool, England; Dr. Francis John Shepherd, Montreal; Sir Thomas Barlow, London, England; Dr. Abraham Jacobi, New York.

The Triennial Dinner.

This was held in Memorial Hall at the close of the exercises. About 700 guests and students were present. Dr. Alfred Worcester, president of the association, presided. Speeches were made by President Eliot, Governor Guild, Professor Welch, Professor Jacobi, Sir Thomas Barlow, Dr. Warren, Professor Keibel and Senor Ramos. All the speeches contained allusions to the new medical school, and the chairman's reference to the occasion as "one common brotherhood" of the medical fraternity all over the world called forth prolonged enthusiasm.

President Eliot emphasized the religious side of medical science, and referred to the deep religious sentiment prevailing in the music rendered by the alumni chorus at the different exercises. He counseled the medical profession to get together and work together in harmony and coöperation to attack moral as well as the physical evils which infest human society. Governor Guild made a most stirring address on the achievements which Massachusetts and Massachusetts men have accomplished for the betterment of mankind. He recalled three notable advances in public health legislation enacted by the Massachusetts legislature during the year 1906, namely, the state care and education of feeble-minded children; the compulsory medical inspection of school children in all the schools of the state, and the law regulating the sale of "patent medicines" containing poisonous drugs.

Sir Thomas Barlow said that he and his colleagues never dreamed of seeing such a vision of beauty, of charm, of absolute adaptation to the needs for which such buildings are erected as that which he had witnessed on this occasion.

Professor Jacobi said that the astounding impression made by the new medical school took him back to the age of Pericles and Phidias.

Congratulatory speechs were made by Professor Keibel and Dr. Ramos. The ceremony was fittingly closed by Prof. J. Collins Warren, who announced that a large general hospital in connection with the new buildings would soon be erected, and that plans were well completed for beginning the undertaking at a very early date.

Correspondence

The Attacks on the American Medical Association.

SAN FRANCISCO, Sept. 21, 1906.

To the Editor:—Please allow me to congratulate you most sincerely on the presentation, in recent issues of THE JOURNAL, of the facts pertinent to the Walker resolutions, which were introduced at the Boston session, and also the explanation of the attitude of the *Medical Record* in its despicable attack on the Association.

In regard to the Walker resolutions, it is rather unpleasant to me to note that my motion, which, you will recall, was to reconsider the motion which placed these resolutions on the table, has been rather generally looked on as an indication of approval of these resolutions. This is most emphatically an error. Dr. Happel correctly stated the intent of my motion in his reply to Dr. Carstens' letter. My desire was to emphasize the rejection of the proposed resolutions, and to prevent any attempt at their subsequent consideration. The President ruled my motion out of order and, while I disagreed with him as to the correctness of his ruling, I did not consider it a point of sufficient importance to raise an objection.

In regard to the oft-reiterated claim of dissensions in the ranks of the Association, of course, I can speak only for our state, but, so far as California is concerned, I take great pleasure in advising you that never before, within my knowledge of society affairs, has there been such a general approval of the American Medical Association and of its many and various important undertakings. Never has dissension been further away than at the present time.

PHILIP MILLS JONES

Standardization of Suprarenal Products.

DETROIT, Sept. 25, 1906.

To the Editor:—A very erroneous impression is likely to be made on the minds of your numerous readers by your editorial on page 944 of THE JOURNAL, September 22. To 19 men out of 20 the clear meaning of the article is that manufacturers do not standardize their suprarenal preparations, whereas, speaking emphatically for ourselves, we do standardize these products, with special reference to our adrenalin and adrenalin solution, ointment and inhalant. We have always done so. In THE JOURNAL as far back as 1902 (see page 150, Jan. 18, 1902), our exact method of standardization was set forth in the fullest detail by our chief pharmacologist, Dr. E. M. Houghton.

We have no objection to government supervision over the suprarenal preparations of the market; some of them need it. But the very thing which you are urging we have performed systematically ever since we began to market *any* of the preparations of the suprarenal gland, standardizing each and every lot of every single preparation and guaranteeing its physiologic activity.

If you will refer to page 1732 of the last edition of the National Dispensatory you will find likewise a complete working method for the assay of adrenalin and other products which are not susceptible of chemical assay.

PARKE, DAVIS & CO.,
Per E. G. SWIFT, General Manager.

Populations of Cities in the Educational Number.

PORTLAND, ORE., Sept. 19, 1906.

To the Editor:—In the Educational Number of THE JOURNAL, August 25, in giving the population of cities, you give Portland, Ore., 98,655, and, while this is taken from the United States census of 1903, it places our city in an unfair position. Our city to-day has a population variously estimated at from 150 000 to 200 000. From all available sources the conservative estimate places our city at 175 000, and this is not "hot air." We have substantial facts to bear us out.

I have asked Governor Chamberlain, Mayor Harry Lane, M.D., of Portland, Auditor Devlin of Portland, and Tom Richardson, manager of the Portland Commercial Club, for estimates, and will enclose their replies. Portland has not been advertised as most western cities have been, and is comparatively little known in the East, and it is only just to give

BYRON E. MILLER, M.D.,
Secretary of the Board of Medical Examiners of the State o
Oregon.

[The letters which Dr. Miller enclosed estimate the present population of Portland at from 150,000 to 178 705. Since the statistics referred to were for last year, the growth in population *subsequent to 1905*, while a matter for congratulation, is immaterial. The figures published were taken from the official estimates made by the Census Bureau in 1903, so as to have a recognized basis. We are glad to give publicity to the facts brought out by Dr. Miller.—ED.]

The Teaching of Medical Jurisprudence.

PHILADELPHIA, Sept. 8, 1906.

To the Editor:—A valuable service to the cause of good medical education was done by your editorial August 25 concerning the extent of teaching of medical jurisprudence i American medical schools. During a considerable part of my active professional life, I was chemist to the coroner and district attorney of this city, and had, therefore, much opportunity to see the necessity of instruction in the determination of causes of death. It seemed sad to see the vast amount of valuable material that was allowed to go to waste in connection with numerous and varied forms of violent death.

In this city the coroner appoints one or more physicians, who make the necessary postmortems and report to the office. As is known throughout the nation, Philadelphia has been for many years in the grip of a political ring, which has no superior in the world for corruption and obstruction. The coroner's office is most important to the great corporations. Verdicts from the coroner have important bearings on damage suits, and in the years in which I was familiar with the coroner's office in this city, it was the custom of one of the street railway companies to give money, generally $5, to the coroner's clerk when a death on that road was under inquiry: In one case, the clerk wanted $10 (probably a difficult case!), but the road would not give more than $5. The result was a verdict blaming the railroad company. The late Mr. Singerly of the Philadelphia *Record* was the principal officer of the road. He immediately set his reporters to work on the records of the coroner's office, exposed a startling amount of corruption and broke up the whole combine by publication of all the details in the *Record*.

It has so happened that almost at no time during the past forty years in this city has a coroner's physician been connected with a medical school in a capacity that would enable him to utilize the material for instruction of students. Most of them have had no teaching positions, and many could not obtain such. In one case a teacher of pathology in a prominent local school was coroner's physician, but he had no interest in medical jurisprudence properly so called, and was, indeed, so unreliable that he would have been a misleader more than a leader.

In THE JOURNAL, September 8, exception is taken by a correspondent to your remark that certain New York schools make no mention of the subject; it is stated that a judge of a New York court delivers fifteen lectures to third-year students at Long Island College. I do not desire to cheapen in any way the work of the person in question, especially as I have not the slightest knowledge of the character and scope of the course, but I wish to state emphatically that lectures by a member of the bar, however eminent and able, are not sufficient as instruction in medical jurisprudence. Experience with trials in criminal courts will amply convince any physician that no lawyer fully appreciates the problems and methods of the science of medicine. For many years I have been a member of the Medical Jurisprudence Society of this city, and I have heard many lawyers, some of them eminent and with a large criminal court experience, discuss question of medical jurisprudence. In most cases they are wholly out of line with the scientific aspects of the case.

The probability is that lectures by a lawyer will cover questions of ethics, general and legal, limitations of professional duties and rights, and cognate questions, but what the medical student needs is practical instruction in the determination of the cause of death. He should have opportunity to see and examine the bodies of the drowned, poisoned, shot and strangulated and victims of other violent deaths; to learn, not by reading or listening, but by seeing, the distinction between still-born and murdered infants, and so on. Then there is the vast field of insanity, so misunderstood by the community at large and so mistried by the courts. In one famous case in this county, in which the evidence of delusional insanity was as clear as day, the trial-judge, one of the most able and honored of the Philadelphia judiciary, shouted out in antagonism to one of the defense witnesses: "If this man is insane, then I wish to say that this is the kind of insanity for which we hang men in Pennsylvania." No, lawyers alone can not conduct a course of medical jurisprudence..

HENRY LEFFMANN.

Nostrums and Advertising.

GUM SPRINGS, VA., Sept. 17, 1906.

To the Editor:—On receipt of bill for renewal of my subscription to the *Monthly Cyclopedia of Practical Medicine*, I acknowledged it by writing them the following letter:

GUM SPRINGS, VA., Aug. 4, 1906.

F. A. Davis Co., Philadelphia.

Gentlemen:—You favor of the 3d inst. received, enclosing bill for subscription to the *Monthly Cyclopedia* for 1906.

Permit me to say, first, that I did not subscribe for this journal for 1906. Second, that while recognizing merits which it has, there are considerations found in its advertising columns which will keep my name off its mailing list.

A casual glance reveals advertisements of such frauds as Antikamnia, Anasarcin, Uric-Antagon, Melachol, Ergo-Apiol (Smith), Keimol, Peptomangan, etc. Continuing, I find, under the caption, "Notes and Comments," a series of "writeups" of numerous proprietaries of this class, such as Neurosine, Vin Mariani, Peptomangan, and others. With these facts before me I do not care to subscribe for the *Monthly Cyclopedia of Practical Medicine.*

Very respectfully,

W. K. McCOY, M.D.

In reply to this I received the following letter:

PHILADELPHIA, Aug. 8, 1906.

Dr. W. K. McCoy, Gum Springs, Va.

Dear Doctor:—Your favor of the 4th inst. duly received. We note that you have passed condemnation on our journal for carrying the ads of firms that have been and are occupying advertising pages in all the leading medical journals of the country, with the exception of THE JOURNAL of the A. M. A., which, however, carries the ad of Vin Mariani, which you refer to in your letter as unethical.

When we feel assured that the mass of the medical profession share your views, we will then take up the question and decide whether or not to continue to publish our journals. Certainly we cannot compete with other publishing houses if we are to be debarred from utilizing this source of revenue which they enjoy. As probably less than a half dozen doctors have expressed an unfavorable opinion of our advertising in five years' time, our opinion is that the mass of the profession are not in sympathy with the views which you express.

This, however, is not to be construed as an endorsement of any pharmaceutical preparation. The idea that we wish to convey is that at present the question is too vague for settlement. We consider the good will of our customers as of a great deal more importance than the interests of an advertiser, and whenever we are convinced that the sentiments of our subscribers are becoming in accord with you own, we shall then, as above stated, decide whether to continue our journals without advertising or discontinue them altogether.

Very truly yours,

F. A. DAVIS COMPANY.

Is it not time that physicians let publishers of medical journals know their opinion regarding the advertising of nostrums? This firm says that their "opinion is that the mass of the profession are not in sympathy with the views which you [I] express." Are they correct? If not, is it not time for us to let them and other publishers know it? Very respectfully,

W. K. McCOY, M.D.

[EDITOR'S NOTE:—If every physician would take the trouble to do as Dr. McCoy did, there would soon be a radical change in the advertising pages of many of our journals, and the most effective blow would be struck at the nostrum evil that it is possible for the profession to strike. Every physician will acknowledge that if the newspapers should refuse to accept the alluring advertisements of fraudulent "patent medicines," the fraudulent "patent medicines" would become a minus quantity. If medical journals should stop publishing advertisements of nostrums, nostrums would soon cease to exist, or nearly so. The F. A. Davis Company says that THE JOURNAL of the American Medical Association carries the advertisement of Vin Mariani. The advertisement of Vin Mariani has not been in THE JOURNAL of the American Medical Association for five years.]

The Oppenheimer Institute and Its Endorsers.

OIL CITY, PA., Sept. 27, 1906.

To the Editor:—The following is a copy of a letter to the *Literary Digest* and Mr. Wagnall's reply. The letter is so wholesome, and its tone on the whole so fair and candid, that I believe it should be given space in THE JOURNAL:

OIL CITY, PA., Sept. 22, 1906.

Funk and Wagnalls, New York.

Gentlemen:—Your circular letter announcing the coming of a new magazine from your press, *The Circle*, and asking that I pledge my support to the new venture by filling and returning the "enclosed card" reached my desk yesterday. Coincidently, and with the same mail, the *Digest* and *Collier's* for to-day, September 22, were received.

It then occurred to me that I had before me a strange combination. On my right, its pages open on the last of the series, "The Great American Fraud," by Samuel Hopkins Adams, lay *Collier's Weekly*. On my left, its advertising pages given to the endorsement of the same, lay the *Digest*. Between the two, pleading, with a wealth of rhetorical diction, for my support, lay the letter.

Judging from its tone, together with the preliminary introduction of the magazine in embryo, the purpose seems plain, i. e., the uplifting of the home circle—hence the title, *The Circle*.

Assuming that a great many of the *Digest* subscribers belong to the medical profession, and as one of the class, I believe we should know in advance the policy which the advertising department of *The Circle* intends to maintain.

Will my sons and daughters in reading the advertising pages of this new magazine

"Find themselves stricken with fear and dismay,
Feeling God or the devil has led them astray?"

A question was then suggested, "Why have I never read an abstract of 'The Great American Fraud' in the *Digest?*" I turned to the *Digest* at my left for the answer. It says (see advertisement of the Oppenheimer treatment):

"The Alcoholic Craving, by Means of the Treatment, is Absolutely Removed in 12 to 48 Hours, and the Patient is Permanently Restored to a Normal Condition."

Impossible. Contrast this statement with the letter written to Oppenheimer by America's honored and loved Mark Twain, in which the Oppenheimer doctor is invited to put his business on a basis of common honesty, etc. Think of it! A man of Mark Twain's standing is moved to invite one, whose dishonest claims have found voice in the *Digest*, to put his business "on a basis of common honesty."

Turning again to the last of the series by Mr. Adams, we are shocked to learn of Mr. Wagnalls, of Funk and Wagnalls, lending his influence to the fake, and with "no personal knowledge of beneficial results or otherwise." Money makes fools of us all. There is that about printers' ink which to the average mind suggests truth. A printed statement will be believed where a verbal one would perish in doubt. How that power has been abused! What a power this has given the press! What a pity to betray such unbounded confidence, such a trust. I am sure that *The Circle* will be a gem in the literary world; if its purpose is to elevate the home, it must necessarily follow that its advertising pages should be kept clean. Promise this, and my influence, small though it is, my voice, weak as it is, my money, scarce as it is, will be gladly given to welcome the coming of *The Circle*. Very truly your,

J. C. O'DAY.

FUNK AND WAGNALLS COMPANY,
Office of the Vice-President.
NEW YORK, Sept. 26, 1906.

Dr. J. C. O'Day, Oil City, Pa.

Dear Sir:—Your letter of 22d inst. is before me. Concerning my name used by an institution, I would say that I am not responsible for the partial statements made by others. When I wrote to Mr. Clemens last November I was particular to say that "my name was used at the beginning" (over twelve years ago) "of the institution *through misunderstanding. Some years ago I positively ordered the withdrawal of my name from the list of advisory directors.*" The original representations made me were quite different from what it seems the institution now is. There never was any money in it. Indeed, if any had been, I positively would have declined in the very beginning. I am not constructed in that way at all. Nor can you find my name anywhere else.

I am pleased to add that the advertising department of the *Literary Digest* has struck that institution off from its list of advertisers admissible to its columns. I am glad Mr. Adams has shown up the concern.

Thanking you for your good words in behalf of *The Circle*, I remain,

Yours very kindly,
A. W. WAGNALLS.

The work of revelation that Mr. Adams has been carrying on in *Collier's* is having its effect, and we who claim to represent all that is high and good in the medical world should willingly encourage those who are giving their columns to the cause.

Very truly yours,
J. C. O'DAY.

Interstate Reciprocity and Frauds in Medical Schools.

SAN FRANCISCO, Sept. 28, 1906.

To the Editor:—The September 15 issue of your esteemed JOURNAL contains a reply of Dr. Harison, secretary of the Michigan Board of Registration, to Dr. Tait of California (letter September 1), and to Dr. Harvey of Massachusetts (article August 25), both of whom consider that system as either pernicious or dangerous, at least under present conditions.

The California statute provides for reciprocity in the discretion of the board of examiners, but the board has thus far remained outside of the reciprocity fold, although often invited to enter. It may interest the profession to know that the reciprocity clause of the California statute was before the Supreme Court of that state in the case, Ex Parte Gerimo, decided on in 1904. Counsel of Gerimo, an ex-judge of the court, attacked the law on the ground of the alleged unconstitutionality of the clause in question. Dr. Harison himself has pronounced against the constitutionality of the particular clause, assigning as his reason that it fails to recognize the so-called rights of practitioners licensed without examination under the former legislation of other states. This objection was directed by the ex-judge against the entire act. The Supreme Court, however, brushed the objection aside, holding that the reciprocity provisions were not an integral part of the statute; that they might be unconstitutional without impairing the validity of the remainder of the act; in which event, the court declared, the effect would be to subject all applicants to the examination. Of course, if Dr. Harison is right in his contentions that the provision for reciprocity is unconstitutional, then all hope for reciprocity between California and her sister states is, under present conditions, gone; for certainly the Board of Examiners can not, at the instance of the enthusiastic apostles of that system, make the statute constitutional.

Dr. Harison distinguishes between absolute and what he is pleased to term restricted or individual reciprocity. The California act would seem to be broad enough to include both forms. Nevertheless, the discretion expressly conferred on the board would have to be exercised within the limitations of the statute, for in California, as elsewhere, the right to reciprocate is derived from the statute. In the language of the act itself, the requirements of the other board must have been at the time of issuing the certificate, in no degree or particular less than those of California at the time it is presented for registration. Is it certain that the requirements of the boards seeking to exchange certificates with California are in no degree or particular less than those of California at the present day?

In California the applicants are known to the examiner by number only, and the secretary can not be an examiner. Judged by the statutes, the ties of blood and of friendship, and more sordid considerations perhaps, would seem to be particularly strong with the medical alma mater, and in this state the legislature has surrounded even the Board of Examiners, although chosen by the profession, with safeguards against fraud. In California the examination of candidates is entirely in writing and the papers must be filed. Any state anxious to reciprocate with California may thus readily ascertain whether the standard of medical knowledge exacted by that state is fully up to her own. Dr. Harison says that under a reciprocity agreement the boards may and are expected to go behind each others' certificates. Michigan, he declares, exercises her right to go behind credentials. Now, if it is advisable that the credentials of an individual applicant should be reinvestigated, why is it not equally advisable that the reciprocating board should have the examination papers of the applicant before it, for without such an inquiry how may it determine whether or not he possesses the qualifications which would have been demanded of him had his application be an original one? All this greatly multiplies the labor the boards, and furthermore, it is contrary to the spirit an purpose of reciprocity. It is not reciprocity at all.

The California board has up to the present time doubted th legality and advisability of reciprocity between herself and the states willing to exchange certificates with her. Nevertheless, she has always been willing to stand shoulder to shoulder with her sister boards in the task of providing competent physicians for the people. She has not favored reciprocity because it looked too much like abdication and surrender of sovereignty when absolute, and as entailing arduous duties and apparently almost impossible of conscientious fulfillment, when restricted and individual. In place of the doubtful advantages and the dangerous tendencies of reciprocity, so clearly illustrated by Dr. Harvey in his admirable paper, California has endeavored to bring about a system of coöperation between boards of examiners for the common good of the profession and the people, whose interests are, after all, identical. Believing that insufficient medical education was the disease responsible for boards of examiners, the California board has sought to take the evil at its source as far as the law permitted it, and two years ago invited interboard coöperation in the matter of the investigation of medical diplomas. The board instructed its secretary to forward to other boards the results of its investigation of credentials, inviting similar information in return. Numerous instances of grave irregularities and even fraud on the part of supposedly high-grade colleges were reported by California. In response a few boards approved of the "plan of reporting candidates failing at the examinations!" None sent any information relating to investigation or rejection of diplomas. What wonder, then, that the impression that eastern boards, Michigan among the number, still failed to go behind diploma and affidavit, so universally the practice under the old régime, should prevail in California. Dr. Harison has neither published nor furnished us with statistics to the contrary.

The California board lays great stress on the investigation of credentials, in obedience to the state statute; and, before reciprocity with other boards can be considered, the members of the board would certainly wish to know whether similar functions are exercised by the boards seeking to reciprocate with California, and also which boards go behind the applicant's affidavit as to his preliminary and medical education.

On behalf of the board I would like to inquire the extent of the rejection of diplomas, if any, and whether any case is within their knowledge, where a certificate procured by fraud was canceled on that ground.

WILLIAM C. TAIT,
Attorney for California Board of Medical Examiners.

San Francisco, Sept. 21, 1906.

To the Editor:—September 1 you published a letter by Dr. Dudley Tait in which statements were made derogatory to the good name of the College of Physicians and Surgeons of San Francisco. Each and all of those statements that in any way reflected on the college mentioned were incorrect. Regarding this case Dr. Tait secured no information and made no effort to secure information from the college authorities. He ignored the fact that this student secured advanced standing on good and sufficient credentials, and took his required work in the summer courses which this college was then conducting. He ignored the further fact that this student was in attendance in the freshman and sophomore years. I have no desire to infringe on your space, but I ask the profession to reserve judgment until both sides are heard. To go into details here would require more space than you are probably willing to grant. Any one who desires the truth regarding the matter may obtain it by writing to me.

D. A. Hodghead,
Dean, College of Physicians and Surgeons of San Francisco.

Internal Administration of Antitoxic Sera.

East Orange, N. J., Sept. 21, 1906.

To the Editor:—May I inquire if any readers of The Journal have administered antitoxic serum in other ways than by subcutaneous injection, and if so, what has been their experience? In England and elsewhere it has been demonstrated clinically that serum given *per os* or *per rectum* is effective, yet one seldom or never hears of these methods being practiced in this country. As the question is of considerable practical importance, it may be interesting to refer to some of the literature on the subject which justifies the change of method.

Within the last few days it has been announced that Professor Behring's latest remedy against tuberculosis, called tulase, is about to be given an extensive trial in the hospitals of France and Germany, and, by his direction, it may be introduced into the system either by subcutaneous injection or by swallowing. This is in accord with the experimental work of others. Figari (*Berlin klin. Woch.*, Jan. 18, 1904), experimenting with the blood of animals immunized against tuberculosis, found that it contained substances which administered to guinea-pigs internally in the form of a powder, raised the agglutinating power of their blood serum and antagonized the action of tuberculous toxins. The same effects were produced by him in the human subject. Roncagliolo administered a similar serum to his patients internally, and also claims to have increased the antitoxic power of the blood with an encouraging therapeutic effect (*Medical News*, Feb. 27, 1904, page 403).

Sera are also efficacious when given *per rectum*. In the London Temperance Hospital, the administration of various sera by rectal injection has been practiced for the last six years, and it has been found they have precisely the same effect as when injected subcutaneously; the action seems equally rapid, while the danger of spreading inflammation and local abscesses at the site of injection is removed (*Lancet*, May 5, 1906).

In an article on "The Treatment of Malignant Endocarditis by the Rectal Administration of Antitstreptococcic Serum," a writer states that he has used this serum in more than 200 cases of septic infection of various kinds, but found that the usual method of injecting the serum under the skin was open to objection. It was so painful that patients, especially if they were stout, dreaded the injection, and it was liable to be followed by rashes of the skin and joint affections. The administration of the serum per rectum was therefore tried, and the result has been so satisfactory in over 25 cases as to lead to the abandonment of subcutaneous injection of the serum (Ib., April 21, 1906, p. 1103).

In a communication on "The Use of an Antistreptococcic Serum in Gonorrheal Infections and in Certain Cases of Purpura Hemorrhagica," Fenwick and Parkinson state that during the last two years they have never encountered a genuine example of gonorrheal rheumatism, either in hospital or private practice, that was not immediately benefited by the serum given per rectum. The effects were immediate, pain being relieved after the second dose, and the tenderness and swelling of the joints rapidly subsiding after the third (*Lancet*, May 5, 1906, p. 1214).

Clinical evidence of the value of antidiphtheritic serum when given by the mouth is furnished by the communications of various physicians to the medical journals (see "Progressive Medicine," Sept. 5, 1905, p. 30). The experience in every case is very similar. One physician relates that two years ago, while injecting the serum, something went wrong with his syringe, and the serum was given by the mouth, with the very happiest results as compared with his previous orthodox cases. Since then he has never used the syringe for this purpose. All his cases were verified by bacteriologic examination (*Brit. Med. Journal*, Dec. 31, 1904, p. 1751). For eight years Paton (Ib., May 5, 1906, p. 1032) has been using by the mouth serums both *normal* and the product of immunity, with remarkable therapeutic results, and the English branch of Parke, Davis & Co. has for years supplied him with a low potency antidiphtheritic serum especially made for oral use.

As to the objection that the digestive juices destroy the antitoxin before it can be absorbed by the system, recent experiment proves the contrary.

"At the last meeting o. the Society of Biology held July 28, 1906, M. Catacuzene and M. Riegler communicated a paper on 'The Toxic Phenomena Following the Administration, *per os*, of Dead Glanders Bacilli.' They had observed that the intrastomachal injection of dead glanders bacilli gave rise to grave symptoms in guinea-pigs, whether young or full grown. The symptoms were those of poisoning followed by death at longer or shorter intervals, or by recovery according to the dose of microbes employed. The preparation of bacilli employed was a culture on glycerin agar, emulsionized in alcohol, in which the bacilli died in a few hours. This emulsion was then centrifuged and the dead bacilli were dried *in vacuo*. When injected into the intestine the dead bacilli gave rise to toxic symptoms varying in gravity with the size of the dose. Not only the soluble portions of the substance, but the very bodies of the bacilli themselves passed out through the intestinal walls and could be detected in the lymphatic glands, in the spleen and in the lungs, in which last organ they produced foci of bronchopneumonia. Small doses given by the mouth produced a tolerance for the poison, provided that three months were allowed to elapse between two doses." *Lancet*, Sept. 8, 1906, p. 688.

To the bacteriologist who injects his serum into guinea-pigs, horses and other of the lower animals, the method employed is a matter of indifference; but to the general practitioner who deals with nervous, excitable children, or with adults who dread the slightest pain, be it only the prick of a needle, it is often an advantage to be able to administer remedies by the mouth instead of subcutaneously, and there is the further advantage of not having to fear the disastrous results which sometimes have followed the injection of an impure serum; at least, this danger is greatly diminished if not actually abolished.

Edward M. Merrins, M.D.

Plaster-of-Paris Dressings.—Dr. R. O. Meisenbach, in th *American Journal of Orthopedic Surgery*, June, has investigated the properties of plaster-of-Paris and brings out som important practical conclusions. The plaster should be manipulated during the initial set, but not after the actual setting has begun. The practice of completing the plaster dressing by rubbing either water or plaster cream on it after th actual set has taken place is entirely wrong, he declares, an tends to weaken rather than to strengthen the dressing Sodium chlorid tends to hasten the setting, but weakens th strength in proportion to the amount added; dextrin increase the strength, but lengthens the time of setting. Starch i small amounts also increases the tensile strength. Portlan cement strengthens the bandage in all its essentials. It als renders the bandages more porous, which permits their bein worn with greater comfort and for a longer time.

Miscellany

Leukemia Treated Successfully with Arsenic.—In the London *Lancet*, Aug. 18, 1906, F. L. Dickson reports the case of a man, aged 24, who had an acute, painful enlargement of the inguinal, right axillary and postcervical glands with slight increase in dulness of the splenic area. The case was diagnosed (after blood examination) as one of acute or subacute lymphatic leukemia and a fatal prognosis was given. Dickson administered liquor arsenicalis, 5 minims, three times a day, and after three days the glandular swellings were less and there was marked improvement in the condition of the blood. The dose of the liquor was increased rapidly to 15 minims, and then gradually diminished. In about two months' time the patient made a complete recovery.

Alcoholism.—In an address given before the medical society of Munich (rep. in *Med. Klinik*, April 1, 1906), Kraepelin credits nearly one-half of the admissions between November, 1904 and November, 1905, to the new psychiatric clinic of that city to alcohol; of the imbecile, 42.9 per cent.; of the epileptics, 65.1 per cent. among the males and 28.5 per cent. among the females; of the manic-depressive cases, 43.5 per cent of the males; of the traumatic psychoses, 23.1 per cent.; in arteriosclerosis, 64 per cent. of the male cases, and of the paretics, 51.9 per cent. in men and 43.5 per cent. in women. With the elimination of alcohol, he thinks, one-third of the cases of paresis could be avoided. Beer drinking seems to be responsible for alcoholic dementia to a large extent in Munich. Kraepelin believes in educational work against alcohol, beginning in the school, and the encouragement of total abstinence.

Diagnosis of Stomach Disorders.—Burdick (*American Journal of Clinical Medicine*) says that in treating stomach troubles the physician should first attempt to answer the following questions: 1. Might the symptoms be caused by any trouble exterior to the stomach, and if so, what? 2. Is the stomach normal as to size and location? 3. Is there food stagnation—in other words, does the stomach empty itself with reasonable promptitude? 4. Are the secretions normal or abnormal? 5. Are there evidences of inflammatory change or other morbid conditions of the mucosa? Preceding this inquiry he should ascertain the family history, the duration of the disease, coexisting affections, the presence and character of pain, and effect of eating and of alkalies on it, conditions of the occurrence of nausea or vomiting, location of tenderness, and the condition of the bowels. The routine attention to these points renders diagnosis and treatment much less difficult, and avoids mortifying mistakes.

Human Sympathy Doctor's Highest Need—A Layman's View.

The following by Chancellor Andrew S. Draper, superintendent of education, New York, appeared in the Chicago *Tribune* as a "lay editorial":

It is too bad that people seem so unable to get rid of a doctor who has become a piece of the family bric-a-brac, when they really want to. The only national society yet to be organized which I can think of, is one which will give the members courage to get rid of physicians of whom they have tired and who have more nerve than they themselves have. If one doesn't like a lawyer he goes to another with his next case, but if he doesn't like his physician he holds on to him with a sternness which philosophy never has explained and experimental psychology has never yet solved. If men and women were not so subject to clap-trap and pretense, they would have better health, pretenders would not be so common nor so persistent, and physicians of worth would be recognized more widely and more uniformly regarded. There is room here for just one more philanthropic national organization, and we ought all to give support to one that would take this good cause in hand.

It needs no mere theory and no bare logic to show that science and sympathy must go together in the successful practice of medicine. The life of every successful physician makes it obvious enough. The lower ranks of the profession are full of men who blunder along and hold on to a weakling or an unfortunate with all of the persistence which credulity permits; but the upper ranks of the profession hold the really successful men in whom human sympathy unites with learning to develop the great soul whom the world recognizes on the instant and for whom it always is eager to remove its hat. The men who are capable of service and who are anxious to serve are the only men worthy of recognition in the medical profession.

And all of us have some sort of claim on the most eminent and successful medical men, and the qualities that have made them successful make them respect it. One who has served whoever called, for small fees or no fees, at all times of day or night, and has come to the time when he can do it no longer and must of necessity discriminate and may in a way fix his own terms, no longer may be bound to respond to every call, but he is bound to have youngsters around him who will, and to keep them straight.

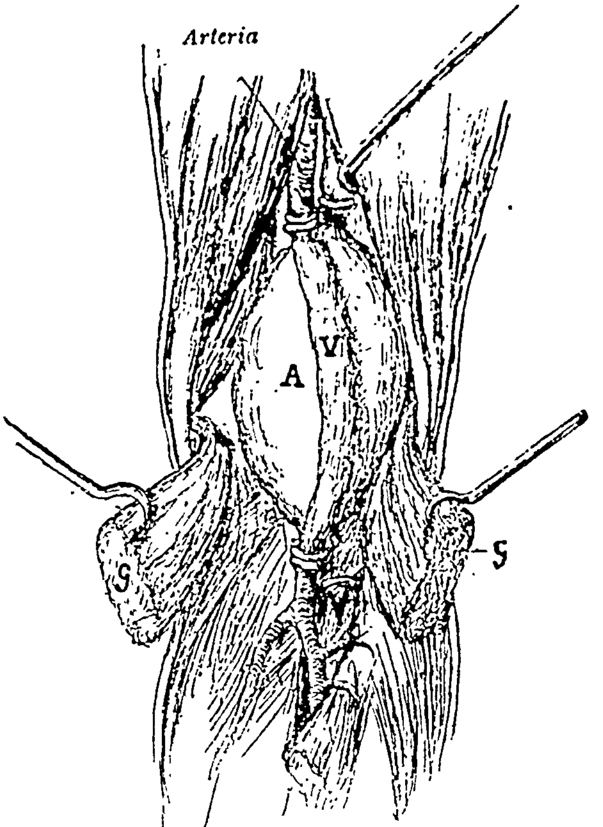
They tell a story of my friend, Dr. Newell Dwight Hillis of Plymouth church, that I do not vouch for, but that easily may be true. It is said that when Dr. Hillis was serving a small church in Evanston, Mrs. Hillis being desperately sick, the young preacher called an eminent specialist, Dr. John C. Webster of Chicago, whose ministrations were successful. Dr. Hillis worried about the bill and after a little went over and said: "Dr. Webster, I can not pay you at once, but I want to know what your bill is, and I will soon arrange it. Here is $50. It is all that I can pay now. Money never can discharge my debt for such eminent services as yours. If you will tell me the amount of your bill I will pay it in full just as soon as I can." Dr. Webster replied: "You keep your money. I owe you as much as you do me. You have made as good in theology as I have in medicine. I will keep Mrs. Hillis out of heaven as long as I can, if you will keep me out of hell as long as you can."

The medical profession is bound to be more than clean and pure and square, more than scientific, and more than sympathetic. It must be steady, cheerful, courageous, optimistic and confident. It is bound to put courage into people to the end that doctor and patient may work together in meeting exigencies and finding the way back to normal health. Half the worth of half the doctors is in their buoyant and bracing temperament.

The medical profession is more than all that; it is a patriotic profession. It is expert on the principles which the state must observe to be healthful and concerning the practices which society must prevent if we are to live in crowded settlements with any degree of comfort and safety. We look to this profession to set up the machinery which may assure the common health and to provide schools, laboratories and hospitals, always expensive, which will make modern scientific knowledge available to the mass and meet the needs of the many who must be overtaken inevitably by accident and disease under the swiftly moving and dangerous conditions of our complex life.

Chloroform Anesthesia.—A. Wilson (*Medical Chronicle*, August, 1906), discusses certain types of accidents from chloroform, which are not well recognized, directing attention particularly to two points. 1. Serious failure of the circulation and impending dissolution are indicated, not by gradual cessation of the respirations, but by exaggerated respiratory movements. 2. In a large class of cases, raising the patient into the sitting position is a most powerful aid toward recovery. Attention was first directed to this procedure and to the reasons for it by Dr. Leonard Hill. These chloroform accidents may result from: 1. Exaggerated action of the muscles in the stage of excitement actively interfering with respiration and circulation. 2. Paralysis or loss of tone of the accessory respiratory muscles so deranging the patency of the respiratory passages that respiration is seriously interfered with. Circulation is also hampered by deficient aeration of the blood and engorgement of the right side of the heart. 3. The specific paralyzing action of the drug on the fundamental nerve centers in the medulla. These accidents happen from some interruption in the orderly progressive course of the narcosis, whereby the circulation or respiration is paralyzed at an early stage of the administration. In the first class of accidents extreme muscular exertion caused by exciting dreams results in sudden heart failure, cyanosis, possibly lividity, with deep, sometimes stertorous, breathing. The signs of danger are the sudden cessation of the struggles and the deep inspirations, associated with dilated pupils and twitching of the arms. The patient should be raised into a sitting position, and the thorax compressed while he is in that position. By alternately raising and lowering the patient, and the steady practice of artificial respiration the whole time, in the majority of cases recovery will ensue, provided always that treatment is begun promptly, whereas if the patient is kept in the recumbent position the danger is increased. In accidents of this class the onset of the failure of circulation is sudden, and the cause mainly due to the paralyzing action of the chloroform on the heart, and partly to the obstruction to the respiration impeding the circulation. It occurs at an early stage of the administration, often before the patient is deeply under. Cases of the second class occur in the later stages of administration from some obstruction to the respiration such as a faulty position of the head and are indicated by less pronounced symptoms. Still Wilson is convinced that if these cases of so-called primary respiratory paralysis were carefully observed, an acceleration of the respiration or signs of increased respiratory activity would be found to precede the final paralysis of circulation and respiration. The symptoms of danger are increased pallor of the face, dilatation of the pupils, exaggerated respiratory efforts, and absence of the pulse. The treatment is the immediate application of artificial respiration, removal of the obstruction to the air passages, and raising the patient into the sitting position to empty the heart. The specific toxic action of chloroform is usually shown first by its action on the circulation and especially on the vasomotors. By this vasomotor paralysis blood accumulates in the splanchnic area and the patient is practically bled into his own vessels and dies with all the symptoms of sudden hemorrhage. In a typical example there is sudden increased activity of the respirations, pallor, dilatation of the pupils and failure of the pulse. Wilson thinks that quickening of the respiration is evident before any change can be detected in the pulse. This condition may occur at any stage of the administration. The symptoms vary according to the degree of anesthesia reached and the condition of the patient. If it occurs early the suddenly-produced anemia will give rise to anemic convulsions. With increased narcosis the muscular disturbance is less, but there is always increased activity of the respiration. This is a gross sign that can not be overlooked, though it is nearly always misinterpreted, he declares. The indications for treatment are to encourage the flow of blood to the heart and nerve centers, to stimulate the heart to renewed contractions, and to restore the blood pressure. With this object in view the patient's head should be placed in a dependent position, the end of the table raised, and energetic artificial respiration performed. Artificial respiration should be applied in such a way that the chest is firmly compressed, so that some pressure is brought to bear on the heart; the intention being not so much to get air into the chest as to stimulate the heart and to raise the blood pressure. The patient ought also occasionally to be raised into the sitting position to prevent the blood stagnating in the vessels of the brain. Prompt treatment, Wilson states, offers good chance of recovery, but exhaustion and rigid chest walls are unfavorable to success. The failure of circulation is so sudden that there is little prospects of drugs being absorbed in time to be of any use. It is better, therefore, Wilson thinks, to rely on artificial respiration.

Substitution of Vein for Artery in Aneurism.—The *Siglo Médico*, Sept. 8, 1906, contains an illustrated description of the successful treatment of a popliteal aneurism by plastic substitution of the popliteal vein for the artery. The operation was performed by J. Goyanes, professor of surgery at Madrid, who credits the idea to Prof. San Martin of Madrid, in 1902. This is the first time it has been applied in the clinic, but experiments on animals had amply demonstrated its feasibility. It has the advantage over other methods, Goyanes says, that the circulation through the artery is retained without trusting to collateral circulation. The sacrifice of the vein is comparatively unimportant at most points where aneurisms are liable to occur. The patient in the present case was a woman of 41, with an extensive fusiform aneurism of the left popliteal artery, considerable arteriosclerosis and a history of syphilis and some alcoholism. The operation included ligature of the artery above and below the aneurism, with compression above. The vein was also ligated above and below the level of the aneurism, and both artery and vein were cut inside the ligatures. The central stump of the artery was then united with the peripheral stump of the vein above the aneurism, and again a similar anastomosis was done below the aneurism. The latter was thus cut off completely from the circulation which passed through the interposed tunnel of vein which lay along the aneurism like a bridge over it. The stumps were sutured by being drawn into the shape of a prism by Carrel's technic. The artery was clamped with forceps above and below the seat of the operation. The lower forceps were taken off first, and then the ones above the aneurism, and lastly the digital compression of the femoral artery in Scarpa's triangle. The blood rushed briskly through the interposed tunnel, and circulation was restored throughout the leg. A fine stream of blood issued from a small accidental puncture hole in the vein, but was arrested at once with a suture. The nerve had been found adherent to the aneurism, which explained the pain previously experienced. The wound healed smoothly, although there was a trifle of suppuration for a few days, evidently due to infection of some gelatin which had been injected as a last resort before attempting surgical intervention. Goyanes thinks that this double arteriovenous anastomosis may possibly have a brilliant future. It might be supplemented by extirpation of the aneurism according to Purmann's technic, especially in case the vein is adherent. The internal saphena seems amply able to take charge of the return circulation in the limb. In the illustration reproduced, A represents the aneurism, V the bridge of vein interposed in the artery in place of the aneurism, and V' the ligated vein below. Goyanes reviews the various other methods of anastomosis of blood vessels in vogue, and states that he has used the Payr technic of anastomosis over a cylinder of absorbable magnesium and



Method of Substitution of Vein for Aneurismal Artery.

found it very safe and simple. The chief drawback is that several millimeters of the vessel have to be sacrificed. His comments on the Matas method indicate that he is not fully acquainted with the principles that govern the technic, or the clinical evidence that has already accumulated in its favor. (See The Journal, Sept. 29, 1906, pages 990, 1017 and 1019.)

Application of Physical Chemistry to Pharmacology.—The importance of physical chemistry to the pharmacologist and physician is shown by T. S. Price in the *Pharmaceutical Journal*, July, by illustrations drawn from the comparative toxicity of different salts as indicated by their power to kill anthrax spores. It is found that mercuric cyanid is far less poisonous than mercuric chlorid, although we should expect the contrary, because it contains the radical of the very poisonous hydrocyanic acid. The explanation of the apparent anomaly is found in the fact that the electrolytic dissociation of the cyanid is less than that of the chlorid. When a compound such as chlorid sodium or sulphate sodium is dissolved in water it separates to a large extent into atoms or groups of atoms, one positive and the other negative, which pass to opposite poles when acted on by the electric (galvanic) current and which, therefore, have been named negative and positive ions, and the process of separation in this way has been called ionization or electrolytic dissociation. A solution of chlorid of sodium contains a mixture of sodium ions and chlorin ions which the electric current separates, the positive sodium ions going to the negative pole and the negative chlorin ions appearing at the positive pole. In the case of sulphate of sodium the separation is into positive sodium ions and negative sulphate ions. The more concentrated the solution of a salt, the less the number of its molecules which separate into ions and the greater the dilution of a solution the more complete the ionization, i. e., the larger the proportion of the salt molecules which are broken up into ions. It has been found that acids which readily undergo ionization when in solution are more powerful as acids and have a correspondingly greater action on the tissues, as a rule, than those which ionize with difficulty. Thus hydrochloric acid ionizes readily and is a strong acid, while acetic acid ionizes less readily and is a weak acid. If in any way we could hinder the ionization of hydrochloric acid we could lessen its activity as an acid. For the weaker acids it appears that the extent of ionization decreases when a salt containing the same negative ion as that of the acid is added to the solution. The acidity of acetic acid is diminished by the presence of an acetate. Mercuric chlorid may be regarded in some respects as analogous to a weak acid. It is a compound of a comparatively weak positive ion with a strong negative one, and it exhibits an acid reaction to litmus paper. If an alkali chlorid is added to mercuric chlorid it is to be expected that the ionization of the mercuric chlorid will be restrained and hence its toxic activity reduced. Such is actually found to be the case, and the disinfectant power of the mercuric chlorid is diminished by the addition of an alkali chlorid such as sodium or ammonium chlorid in proportion to the amount of alkali chlorid added and to the strength of the solution. That is to say, the greater the dilution the greater the tendency to dissociation or ionization and the less the inhibition of ionization on account of the presence of sodium or ammonium chlorid. These additions, therefore, while increasing the solubility of the mercury salt, diminish to a limited extent its toxicity and disinfecting power. Practically, however, as the disinfectant is used in dilute solution a marked diminution of disinfectant power is not to be feared. Still more striking is the effect of the production of certain double salts of mercury or silver on the toxicity of these metals. Thus yellow mercuric oxid dissolves in potassium thiosulphate to form a solution containing a new combination which dissociates into potassium ions and those of a complex group containing each an atom of mercury. The mercury is no longer present as mercury ions and does not exert the activity of the ordinary mercury ion. The salt would be expected to be nonpoisonous and such, in fact, is the case. Similarly the toxic effect of silver salts can be reduced by the addition of sodium thiosulphate: the Ag ion combines with the thiosulphate ion (S_2O_3) to form the complex ion AgS_2O_3, which is non-toxic.

Book Notices

Physiology and Therapeutics of the Harrogate Waters, Baths and Climate. Applied to the Treatment of Chronic Disease by W. Bain, M.D. and W. Edgecombe, M.D. Cloth. Pp. 300. Price, $2.60 net. New York: Longmans, Green & Co, 1905.

This work is based on experimental research and clinical observation, and will be found of most value to those who wish to employ the particular spring referred to. The action and therapeutic value of all natural mineral waters, however, is made clear by the introductory chapter which discusses the chemical and physical action of the waters, both within the body and experimentally. This elementary review of osmosis and electrolysis gives the reader a very much clearer understanding of the subsequent exposition of mineral waters in general, the Harrogate waters in particular. Section 1 is devoted to the pharmacology and the physiologic and therapeutic action, and Section 2 classifies the baths. Section 3 discusses the factors which determine climate, as, for example, temperature, humidity, rain fall, sunshine, winds, etc. Features of the town are briefly described, sanitary conditions, etc. The final section of the book is devoted to a detailed description of the chronic diseases which may be treated by the waters, baths and climate. The authors have logically paved their way for the presentation in tabulated form of the great variety of diseased conditions which have been benefited by the spa treatments. Other factors in the treatment, such as diet, exercise and drug therapy have not been lost sight of. We are glad to note that exaggerated claims of results, which are so commonly made for a treatment so diversified in its application, find an unusually small place in this book.

Physiology of the Nervous System. By J. P. Morat. Authorized English Edition. Translated and Edited by H. W. Syers, M.A., M.D., Physician to the Great Northern Central Hospital. With 263 Illustrations. Cloth. Pp. 680. Price, $7.50 net. Chicago: W. T. Keener & Co., 1906.

There is no subject in medicine which requires a more accurate knowledge of the anatomy and physiology than does the nervous system, in order to be able to reason out the pathologic conditions. The physiology of the nervous system, however intricate, must be fairly well understood by the teacher in order to aid the student to grasp this difficult subject. If this part of the student's instruction is neglected his interest in the clinical study of nervous diseases will necessarily be below the proper standard, as the pathologic reasoning must be based on a knowledge of the anatomy and physiologic relations of the parts involved.

In his researches and writings Morat has elucidated a great many theories and has given to the medical profession advances in the physiologic functions of the nervous system by going more deeply than former investigators into the functions of certain centers and, in some instances, by correcting the opinions of other writers. The chapter on "Superior Systemizations" is of special interest. The illustrations given are of value in connecting the clinical and pathologic findings with the physiology of the part involved. To those interested in the study of the diseases of the nervous system this work can be recommended.

Human Sexuality, a Medico-Literary Treatise on the Laws, Anomalies, and Relations of Sex, with Especial Reference to Contrary Sexual Desire. By J. R. Parke, Sc.B., Ph.G., M.D. (Late Acting Assistant Surgeon, U. S. Army). Cloth. Pp. 476. Price, $3.00. Philadelphia: Professional Publishing Company, 1906.

This is a valuable addition to the literature on the subject. It is a readable volume, and, for most practitioners, will be found more satisfactory than many of the elaborate works which treat of the various phases of the subject in more detail. It presents a summary of what is known of the customs of all peoples as regards sexual selection, betrothal, marriage, divorce, etc., and the relation of the sex problem to modesty, vanity, poverty, wealth, morality, Christianity, civilization, virtue and the welfare of the race. In the main, the attitude of the author is judicial, broad-minded and helpful, but he has been led far astray in his endeavor to treat the subject with entire disregard of so-called prudery. Sexual matters should be treated with perfect frankness, particularly in a work for physicians, but we can not justify the author in his facetious and flippant manner of telling unnecessary stories and of illuminating some pages with headlines of questionable wit. It is regrettable that an author whose general attitude is so evidently wholesome should thus mar his book. The publisher advertises that the book "reads like a novel," which, we submit, is hardly necessary in such a work.

Clinical Bacteriology and Hematology for Practitioners. By W. D. Emery, M.D., B.Sc., Clinical Pathologist to King's College Hospital and Pathologist to the Children's Hospital, Paddington Green. Cloth. Pp. 240. Price, $2.00. Philadelphia: P. Blakiston's Son & Co., 1906.

The present edition of this work contains many improvements over the previous edition. More space is given to the bacteriologic examination of materials from special parts of the body and to the examination of blood, especially with reference to the diagnosis of disease. The technical part of the work has been rewritten to include descriptions of new methods and new apparatus.

Hygiene of Pregnancy. By W. B. Jennings, Ph. B., M.D., Attending Physician (O.P.D.), St. Mary's Free Hospital for Children. Flexible Leather. Pp. 48. New York: Medical Review of Reviews.

This monograph is intended for the use of nurses and expectant mothers. The language used is simple and few technical terms are used.

Marriages

JOSIAH CALVIN McCRACKEN, M.D., Canton, China, to Miss en Newpher of Cleveland, Ohio, September 12.

DAVID HENRY FITZGERALD, M.D., Fond du Lac, Wis., to Miss lian Virginia Gannon of Chicago, October 3.

J. H. DUNCAN, M.D., Killbuck, Ohio, to Miss Alberta Esther gan of Mechanic Township, September 19.

ANDREW MOYNIHAN, M.D., Sauk Center, Minn., to Miss ma Collins of St. Paul, September 25.

HARRY R. BROWN, M.D., Chillicothe, Ohio, October 3.

Deaths

Eduardo Andrade, M.D. University of Georgetown, Medical epartment, Washington, D. C., 1894; a member of the American Medical Association; bacteriologist of the State Board of ealth of Florida; a member of the Duval County (Fla.) edical Society, and one of the most brilliant and popular oung practitioners of Jacksonville, Fla., died suddenly in New ork City September 20, aged 33. The State Health Officer f Florida pays the following tribute to the memory of Dr. ndrade: "Words can not convey nor can human tongue exress the grief which the State Board of Health feels in the oss of its talented associate, who, although young in years, evertheless possessed the mental qualities of an accomlished and polished scholar and scientist, and typified in very act of life all the attributes of a Christian gentleman." The Jacksonville Board of Trade and the Duval County Medcal Society appointed special committees to attend the funeral.

William K. Otis, M.D. College of Physicians and Surgeons n the City of New York, 1885; a member of the American Association of Genitourinary Surgeons, American Urological Association, New York Academy of Medicine, St. Luke's Alumni Association; Hospital Graduates Club; New York County Medical Society and Medical Association of the City of Greater New York; professor of genitourinary diseases in the New York School of Clinical Medicine; attending surgeon to St. Mark's Hospital and the West Side German Dispensary; consulting surgeon to the City Hospital and the Throat and Nose Hospital, died suddenly at his home in New York City, September 22, from pneumonia, aged 36.

Walter Clarke Jackson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1852; a member of the Alabama State Medical Association before the Civil War, one of the reorganizers of the association in 1868, and for several years its treasurer; once president of the Medical and Surgical Society of Montgomery; one of the ten physicians who in 1872 organized the Social Medical Club in Montgomery, died at his home in Montgomery, September 22, after an illness of only three days, aged 79.

Albert R. Ong, M.D. Columbus (Ohio) Medical College, 1877, a member of the American Medical Association, one of the most prominent physicians of Martins Ferry, Ohio; for a number of years professor of mathematics and astronomy and vice-president of Richmond College; a member of the Board of Pension Commissioners and chief of the Volunteer Fire Department of Martins Ferry, died suddenly at his home in that city, September 22, from acute gastritis, aged 58.

Francis Perley Taylor, M.D. Pennsylvania Medical College, Philadelphia, 1857, L.R.C.P., Edinburgh, 1865, and F.R.C.P., Edinburgh, 1871; one of the founders and a constant patron of the Prince Edward Island Hospital, and for many years a member of the Charlottetown Board of Education; one of the most prominent and beloved practitioners of Prince Edward Island, died at his home in Charlottetown, September 17, after an illness of only half an hour.

Andrew Fine, M.D. Toland Medical College, San Francisco, 1866; one of the best known practitioners of Oakland, Cal.; for 21 years a member of the California State Board of Pension Examiners; consulting physician to the Home for the Adult Blind, and for several terms a member of the Board of Education of Oakland, died at the home of his son in that city, September 20, after a long illness, aged 63.

John M. Buckingham, M.D. Jefferson Medical College, Philadelphia, 1852; a member of the American Medical Association, Ohio State Medical Association, Southwestern Ohio Medical Society and Clark County Medical Society; a member of the staff of the Springfield City Hospital, and health officer of Springfield, Ohio, died suddenly in that city, September 27.

Thomas H. Helsby, M.D. University of Maryland School of Medicine, Baltimore, 1859; surgeon in the Fifth Army Corps during the Civil War, and for 30 years thereafter a practitioner in Williamsport, Pa., died at his home in Baltimore, September 26, aged 71.

Thomas F. M. Phelan, M.D. Bellevue Hospital Medical College, New York City, 1882; city physician of Orange, N. J., in 1891, and health officier, died from general paresis, at a sanitarium in Worcester, Mass., September 11, after an illness of several years.

William B. Foster, M.D. Medical Department of the University of Louisiana, New Orleans, 1850; one of the oldest and most highly respected physicians of Hope, Ark., died September 14, at a sanitarium in Texarkana, after a surgical operation, aged 84.

Charles E. C. Beach, M.D. Fort Wayne (Ind.) College of Medicine, 1905; interne at Hope Hospital, Fort Wayne, in 1903 and 1904, died at his home in Coesse, Ind., September 20, from cerebral congestion, after a short illness, aged 27.

George S. Rittenhouse, M.D. Jefferson Medical College, Philadelphia, 1880, a member of the Cecil County Medical Society, died at his home in North East, Md., September 22, from tuberculosis, after a lingering illness, aged 49.

Samuel Wesley Lippincott, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1897, of Phildelphia, died at the University Hospital, September 22, from hemorrhage due to gastric ulcer, aged 36.

William D. Kerr (Years of Practice, W. Va.), for forty years a practitioner of that state, while making a professional call near his home at Huntington, Dec. 13, 1905, was struck by a railway train and instantly killed.

Thomas C. Dodson, M.D. New York University, New York City, 1849, of Mount Vernon, Texas, died suddenly September 18, at the home of his daughter in Tishomingo, I. T., from heart disease, aged 78.

Daniel M. Skinner, M.D. New York University, New York City, 1858; a surgeon in the Navy during the Civil War, died at his home in Belleville, N. J., September 26, from cerebral hemorrhage, aged 71.

G. W. Wilson, M.D. University of Nashville, Medical Department, 1902, of Westmoreland, Tenn., died at a hospital in Nashville, September 15, five days after an operation for appendicitis, aged 43.

Ambrose H. Martin, M.D. Jefferson Medical College, Philadelphia, 1885; for a number of years a practitioner of Pendleton, Ore., died in Portland, Ore., September 18, after a surgical operation.

Higgins C. Smith, M.D. Bellevue Hospital Medical College, New York City, 1869, died at his home in Broadwell, Ky., September 17, from disease of the stomach, after a long illness, aged 70.

James C. Miller, M.D. Jefferson Medical College, Philadelphia, 1885, of Jeannette, Pa., died at the Westmoreland (Pa.) Hospital, September 22, from pneumonia and uremia, aged about 50.

William J. Cox, M.D. Kentucky School of Medicine, Louisville, 1894, of Uniontown, W. Va., died at the North Wheeling Hospital, Wheeling, W. Va., from nephritis, September 15.

M. M. T. Hutchinson, M.D. Medical College of Georgia, Augusta, 1859, for three years a member of the School Board of Thomasville, Ga., died at his home in that city, August 21.

Richard Sanford, M.D. London (England) Hospital, 1849; assistant surgeon during the Yakima Indian War, died at his home in Glencoe, Ore., August 29, aged 83.

Albert L. Walker (Examination, Michigan) died from accidental poisoning, at his home in Ann Arbor, Mich., August 31, after an illness of two days, aged 57.

H. E. Babcock, M.D. Albany (N. Y.) Medical College, 1855, died at his home in New London, N. Y., September 20, after an invalidism of four years, aged 79.

J. Y. Campbell, M.D. Chicago Medical College, 1865, for 25 years a practitioner of Paxton, Ill., died at his home near Rochester, Ind., September 21.

George W. A. Collard, M.D. Hahnemann Medical College and Hospital, Chicago, 1880, died at his home in Bridgeport, Conn., September 18, aged 75.

Adam Orr, M.D. Queen's College, Cork, Ireland, 1862; M.R.C.S., Edinburgh, 1864; died at his home in Allegheny, Pa., September 25, aged 66.

William Jasper Packwood, M.D. University of Buffalo, Medical Department, 1876, died suddenly at his home in Buffalo, September 24, aged 54.

Oscar Alfred Fliesburg, M.D. College of Physicians and Surgeons, Chicago, 1885, died at his home in Minneapolis, Minn., September 12, aged 55.

George W. Davies, M.D. College of Physicians and Surgeons of Chicago, 1895, was found dead at his home in Waterloo, Wis., September 22.

Chauncey B. Howe, M.D. Syracuse (N. Y.) Medical College, 1861, of Seneca Falls, N. Y., died in the Geneva Hospital, August 27, aged 80.

Harvey Dunn, M.D. St. Louis Medical College, 1867, died at his home in Perry, Ill., September 11, after an illness of several years, aged 72.

Eva M. L. Scobell, M.D. Hering Medical College and Hospital, Chicago, 1899, died at her home in Chicago, September 11, aged 33.

J. J. Wilkinson, M.D. Philadelphia University of Medicine and Surgery, 1868, died at his home in Orland, Ind., September 6, aged 64.

Charles W. Pfeffer, M.D. Baltimore Medical College, 1883, died at his home in Baltimore, September 22, after a lingering illness.

William F. Wallace, M.D. Columbus (Ohio) Medical College, 1880, died at his home in Rochester, N. H., recently.

Deaths Abroad.

Hermann Cohn, M.D., the well-known ophthalmologist and hygienist, died at Breslau, September 14, aged 68. He began his scientific career with physics and chemistry, and then devoted himself to medicine, presenting theses in each of these branches of science. Since 1866 he has confined his efforts to ophthalmology and hygiene, and has won fame and honors in both. He has published more than 200 articles on subjects in these lines, besides a number of manuals and compilations of statistics, etc. His first important work was his famous study of the condition of the eyes of 10,060 school children, with suggestions for the hygiene of the eyes during school life. This was followed by "The School of the Future," "Tests for Vision," "How Can the School Combat Masturbation Among the Children"? etc. One of his latest communications proclaimed the efficacy of radium in treatment of trachoma.

O. Vierordt, M.D., professor of internal medicine and pediatrics at Heidelberg, died September 2, aged 50. He was stricken with cardiac paralysis while greeting the members of the German medical study trip as they were visiting his clinic on their rounds through Heidelberg.

W. Czermak, M.D., professor of ophthalmology at Prague, died September 8, aged 50. He has published numerous articles on his specialty, on the origin of glaucoma, corneal fistula, etc., besides a manual of ophthalmology and guide to operations on the eyes.

G. A. Morache, M.D., professor of legal medicine at Bordeaux, died recently, aged 69. He was sent by the French government to China and elsewhere on several special medical missions.

A. Högyes, M.D., director of the Pasteur Institute at Budapest, formerly professor of internal medicine, died September 7.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

INFORMATION WANTED REGARDING PUBLIC CARE AND TREATMENT OF INSANE.

SALINA, KAN., Sept. 24, 1906.

To the Editor:—I am looking for a book or publication which will give me some practical information regarding public care and treatment of our unfortunates. Will you kindly help me toward this end?

O. D. WALKER, M.D.

COUNTER-IRRITANTS IN PNEUMONIA.

WARSAW, VA., Sept. 12, 1906.

To the Editor:—1. When are the following counter-irritants indicated in pneumonia: (a) Blisters in lobar pneumonia? (b) Mustard plasters, poultices or paste in bronchopneumonia?

2. Will statistics show a lower percentage of mortality or shorter duration of disease by their use? L.

ANSWER.—1. The question of the use of counter-irritants in pneumonia is one on which opinions differ widely. By many, the use of these remedial agents is regarded as entirely useless; others believe that particularly at the beginning of pneumonia, when there is severe pain, not only is relief from pain obtained by these local applications, but that in some way the course of the disease is modified. That pain may be relieved by the use of hot applications, poultices, plasters and blisters, we think can not be doubted. That lobar pneumonia or bronchopneumonia are modified in their course by such applications is not believed by clinicians generally; and often more harm than good is done by the pain and annoyance from the applications, from the mechanical interference with respiration caused by heavy poultices or plasters, and by alternate heating and chilling of the body due to poultices becoming cold. We know of no special indication for the use of these applications in broncho-pneumonia.

2. No.

TREATMENT OF "CANKER SORES."

LORAINE, ILL., Sept. 19, 1906.

To the Editor:—Will you kindly publish in THE JOURNAL a good treatment for canker sores of the mouth? X. Z.

ANSWER.—The expression "canker sores of the mouth" may cover a multitude of sins, from a dirty, sour nursing bottle causing sore mouth in an infant, to the mucous patches of syphilis. Therefore, a knowledge of the cause is of the first importance in the treatment. The cause may be purely local, as when a burn produces vesiculation in the mouth, or it may be practically entirely constitutional, as in syphilis. In the usual case, as seen in infants and children, a combination of both conditions commonly exists, and the more obstinate the case the more influential the constitutional element. Of the local causes, sour and improper foods, with a lack of cleanliness of the mouth, play the most important rôle. Of the constitutional conditions, scurvy, ricketts, syphilis, the depressed state following the acute infectious diseases, etc., are the most important. The treatment, therefore, must be both local and general. The food should be pure and sweet and such as the child can properly digest. It should be given cool because warm drinks irritate the mouth more than cold ones. With a clean camel's hair brush or fresh cotton swab the spots may be touched gently but thoroughly with a solution of from 0.5 per cent. to 1 per cent. of permanganate of potassium or a solution of from 1 to 2 per cent. of nitrate of silver. If the pain is so severe that the child can not be made to take any nourishment the sore spots may be carefully touched with a 2 per cent. solution of cocain, which will deaden the pain for the time being so that the child will nurse. This, of course, should only be used by the physician himself or by a perfectly competent trained nurse under his direction. A diet suitable to the age and condition of the child, at times with tonics, should be prescribed for the general condition. Syphilis, of course, requires its own specific treatment.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending September 29, 1906:

Kirby-Smith, R. M., asst.-surgeon, left Army General Hospital, Presidio of San Francisco, on 30 days' sick leave of absence, with permission to apply for two months' extension.

Hoff, John Van R., asst.-surgeon-general, relieved from duty as chief surgeon, Dept. of the Missouri, and will proceed to San Francisco, and take transport to sail Nov. 5, 1906, for the Philippine Islands, and on arrival at Manila will report in person to the commanding general, Philippines Division, for assignment to duty.

Girard, Joseph B., asst.-surgeon-general, relieved from duty as chief surgeon, Philippines Division, and will proceed to San Francisco, on transport sailing from Manila in December, 1906, reporting on arrival in the United States to the Military Secretary of the Army for further orders.

Rhoads, Thomas L., asst.-surgeon, relieved from duty at U. S. Military Academy, West Point, N. Y., and ordered to Fort Crook, Neb., for duty.

Smith, Herbert M., asst.-surgeon, advanced to the rank of captain from Sept. 20, 1906.

Cox, Walter, asst.-surgeon, leave of absence extended two months.

Hoff, John Van R., asst.-surgeon-general, relieved from duty at camp of instruction at Fort Riley, Kan., and will return to his proper station at Omaha.

Barlett, C. J., asst.-surgeon, advanced to the rank of captain, from September 21.

Jones, Harold W., asst.-surgeon, will accompany 14th Cavalry from Sequoia and the General Grant national parks, to Presidio of Monterey, Cal., and report, on arrival, for temporary duty. Also to report by letter to commanding general of the department for further orders.

Carter, Wm. F., surgeon, granted leave of absence for one month, to take effect about October 6, with permission to apply for one month's extension.

Davis, Wm. B., deputy surgeon general, left Headquarters, Department of the Lakes, Chicago, on 21 days' leave of absence.

Ford, Clyde S., asst.-surgeon, will repair from New York City to Washington, D. C., and report in person to the Military Secretary of the Army for instruction in the matter of personal identification record.

Koerper, C. E., asst.-surgeon, granted thirty days' leave of absence.

Lynch, Charles, surgeon, general staff, leave of absence extended fifteen days.

Love, Albert G., asst.-surgeon, will accompany troops from Yosemite National Park to Presidio of San Francisco, on arrival at the latter post to report for temporary duty, also report in person to the commanding general, Department of California, for further orders.

Wakeman, Wm. J., surgeon, left Fort Thomas, Ky., on thirty days' sick leave of absence.

Wadhams, S. H., asst.-surgeon, will accompany Companies B and D, 4th Infantry from Fort Slocum, N. Y., to Fort Mackenzie, Wyo., instead of First Lieut. James D. Fife, asst.-surgeon, previously assigned to this duty.

Morris, Samuel J., asst.-surgeon, ordered to proceed from Fort Schuyler, N. Y., to New York City, and report in person to commanding officer, U. S. Army Transport *Sumner* for duty as transport surgeon.

Shellenberger, James E., contract surgeon, granted an extension of two months to his sick leave of absence.

Hutson, T. Ogier, contract surgeon, returned to Fort McPherson, Ga., from temporary duty at Fort Moultrie, S. C.

Hereford, John R., contract surgeon, ordered from Fort Caswell, N. C., to Fort Screven, Ga., for temporary duty.

Hasseltine, Hermon E., contract surgeon, ordered from Bristol, Vt., to Fort Thomas, Ky., for duty.

Myers, William H., contract surgeon, relieved from duty at Washington Barracks, D. C., and ordered to the Army Medical School for a course of instruction.

Johnson, Howard H., contract surgeon, relieved from duty at the Army General Hospital, Washington Barracks, D. C., and ordered to the Army Medical School for a course of instruction.

Macy, Fred S., contract surgeon, relieved from duty at Fort Adams, R. I., and ordered to the Army Medical School, Washington, D. C., for a course of instruction.

The following contract surgeons have been ordered from the places designated to Washington, D. C., for a course of insrruction at the Army Medical School: Rukke, Guy V., Ann Arbor, Mich.; Bryan, Ray W., St. Louis; Pillsbury, Henry C., Boston; Christie, Arthur C., Clymer, N. Y.; Gostin, Bernard S., Macon, Ga.; Bartlett, William K., Minneapolis, and King, Edgar, Van Buren, Ark.

Hogan, David D., contract surgeon, relieved from duty at Fort Hamilton, N. Y., and temporary duty at Fort Jay, N. Y., and ordered to Fort Schuyler, N. Y., for duty.

Stone, Frank P., dental surgeon, returned to duty at Fort Sam Houston, Texas, from leave of absence.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending September 29, 1906:

Bell, W. H., surgeon, to special duty in the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

De Bruler, J. P., asst.-surgeon, detached Navy Yard, Washington, D. C., etc.: to special duty in the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Benton, F. L., surgeon, detached Naval Hospital, Navy Yard, Pensacola, Fla., to the *Texas*.

Langhorne, C. D., surgeon, to the *Brooklyn*.

Freeman, G. F., P. A. surgeon, to duty Naval Hospital, Portsmouth, N. H.

Webb, U. R., P. A. surgeon, detached Naval Hospital, Portsmouth, N. H., to the *Brooklyn*.

Backus, J. W., P. A. surgeon, detached U.S.R.S. *Franklin*, Navy Yard, Norfolk, Va., to the *Texas*.

Moore, A. M., surgeon, retired, to Navy Recruiting Station, Memphis, Tenn.

Page, J. E., surgeon, to Naval Hospital, Norfolk, Va.

Tolfree, H. M., P. A. surgeon, detached Naval Hospital, Norfolk, Va., to the *Connecticut*.

Taylor, E. C., asst.-surgeon, detached U.S.R.S. *Hancock*, Navy Yard, New York, N. Y., to duty Naval Hospital, New York.

Rennie, W. H., asst.-surgeon, detached U.S.R.S. *Lancaster*, Navy Yard, League Island, Pa., to duty Naval Hospital, Pensacola, Fla.

Lovering, P. A., medical inspector, detached from duty as member of Naval Medical Examining Board, to duty in command of Naval Hospital, Norfolk, Va.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissoned officers of the Public Health and Marine-Hospital Service for the seven days ending Sept. 26, 1906:

Gassaway, J. H., surgeon, granted leave of absence for three days.

White, J. H., surgeon, granted leave of absence for seven days from Sept. 23, 1906.

Guiteras, C. M., surgeon, granted leave of absence for one day.

Wertenbaker, C. P., surgeon, granted extension of leave of absence for seven days from Sept. 22, 1906.

Stimpson, W. C., surgeon, granted leave of absence for two days from Sept. 21, 1906.

Lavinder, C. H., P. A. surgeon, relieved from temporary duty at Detroit and directed to proceed to Stapleton, N. Y., reporting to the Medical Officer in Command for duty and assignment to quarters.

Grubbs, S. B., P. A. surgeon, granted leave of absence for two days.

Hobdy, W. C., P. A. surgeon, detailed to represent the Service at the semiannual meeting of the California Public Health Association at San Jose, Cal., Oct. 10, 1906.

Ward, W. K., asst.-surgeon, granted leave of absence for seven days from Sept. 24, 1906, under the provisions of Paragraph 191 of the Regulations.

Gibson, L. P., acting asst.-surgeon, granted leave of absence for five days.

James, W. F., acting asst.-surgeon, leave of absence granted without pay to Acting Assistant Surgeon James for fifteen days from August 31, 1906, revoked.

Scott, E. B., pharmacist, granted leave of absence for twenty-three days from Aug. 23, 1906, on account of sickness.

Scott, E. B., pharmacist, granted leave of absence for twenty-four days from Sept. 20, 1906.

Slough, Charles, pharmacist, relieved from duty at Honolulu, T. H., and directed to proceed to San Francisco, reporting to the Medical Officer in Command for duty and assignment to quarters.

Beck, J. E., pharmacist, relieved from duty at San Francisco, and directed to proceed to Honolulu, T. H., reporting to Chief Quarantine Officer for duty and assignment to quarters.

Iltis, George W., pharmacist, granted leave of absence for thirty days from Sept. 22, 1906.

Hall, L. P., pharmacist, granted leave of absence for seven days from Sept. 23, 1906, under Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the year ended September 28, 1906:

SMALLPOX—UNITED STATES.

Indiana: South Bend, Sept. 16-22, 1 case.
Kentucky: Lexington, Sept. 8-15, 1 case.
Louisiana: New Orleans, Sept. 8-15, 7 cases (6 imported).
Ohio: Cincinnati, Sept. 14-21, 1 case.
Pennsylvania: Altoona, Sept. 15-22, 1 case, 1 death.

SMALLPOX—FOREIGN.

Africa: Cape Town, Aug. 4-18, 8 cases.

Brazil: Bahia, Aug. 11-18, 6 cases; Pernambuco, Aug. 1-15, 3 deaths; Rio de Janeiro, Aug. 12-Sept. 2, 10 cases.

Chile: Antofagasta, July 29-Aug. 12, 39 cases, 4 deaths; Coquimbo, 30 cases, 1 death; Talcahuana, present.

India: Bombay, Aug. 14-28, 4 deaths; Calcutta, Aug. 4-11, 2 deaths; Karachi, Aug. 12-26, 5 cases, 2 deaths; Madras, Aug. 4-17, 3 deaths.

Russia: Moscow, Aug. 18-25, 2 cases; Odessa, Aug. 25-Sept. 1, 6 cases; St. Petersburg, Aug. 18-25, 2 cases, 1 death.

Siberia: Vladivostok, July 28-Aug. 4, 1 case.

Spain: Barcelona, Sept. 1-10, 8 deaths; Seville, Aug. 1-31, 31 deaths.

Turkey: Constantinople, Aug. 26-Sept. 9, 2 deaths.

YELLOW FEVER.

Cuba: Habana, Sept. 27, 2 cases.

Ecuador: Guayaquil, Aug. 1-31, 9 deaths.

Mexico: Merida, Sept. 2-15, 5 cases, 4 deaths; Tuxtepec, 4 cases, 5 deaths; Vera Cruz, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, July 28-Aug. 4, 38 cases, 30 deaths; Provinces, July 28-Aug. 4, 731 cases, 534 deaths.

CHOLERA—FOREIGN.

India: Bombay, Aug. 14-28, 89 deaths; Calcutta, Aug. 4-17, 8 deaths; Madras, 19 deaths; Rangoon, Aug. 11-18, 1 death.

PLAGUE—INSULAR.

Hawaii: Honolulu, Aug. 18-25, 1 case, 1 death.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Aug. 12-Sept. 2, 8 cases, 4 deaths; Pernambuco, Aug. 1-15, 2 deaths.

Egypt: Alexandria, Aug. 28-29, 2 cases, 4 deaths; Suez, Aug. 24-25, 2 deaths.

India: General, July 28-Aug. 11, 2,321 cases, 167 deaths; Bombay, Aug. 14-28, 61 deaths; Calcutta, Aug. 4-11, 2 deaths; Karachi, Aug. 12-26, 10 cases, 8 deaths; Rangoon Aug. 4-18, 205 deaths.

Japan: Formosa, Aug. 10-20, 3 cases, 3 deaths.

Peru: Lima, Aug. 18-25, 7 cases, 4 deaths; Mollendo, 1 case, 1 death; Paita, 3 cases, 2 deaths.

State Boards of Registration

COMING EXAMINATIONS.

GEORGIA Board of Medical Examiners (Regular), Capitol, Atlanta, October 9. Secretary, E. R. Anthony, Griffin.

ARKANSAS State Medical Examining Board, Little Rock, October 9. Secretary, J. P. Runyan, Little Rock.

KANSAS State Board of Medical Registration and Examination, State House, Topeka, October 9. Secretary, F. P. Hatfield, Grenola.

MICHIGAN State Board of Registration in Medicine, Lansing, October 9. Secretary, B. D. Harison, Detroit.

MISSISSIPPI State Board of Health, The Capitol, October 9. Secretary, J. F. Hunter, Jackson.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, October 11. Secretary, Geo. C. Ober, Washington.

NEW JERSEY State Board of Medical Examiners, Trenton, October 16-17. Secretary, J. W. Bennett, Long Branch.

TEXAS State Board of Medical Examiners, Houston, October 16-18. Secretary, T. T. Jackson, San Antonio.

FLORIDA Board of Medical Examiners (Regular), Jacksonville, October 17-18. Secretary, J. D. Fernandez, Jacksonville.

ILLINOIS State Board of Health, Great Northern Hotel, Chicago, October 17-19. Secretary, J. A. Egan, Springfield.

LOUISIANA State Board of Medical Examiners, New Orleans, October 19-20. Secretary, F. A. Larue, New Orleans.

KENTUCKY State Board of Health, Louisville, October 23. Secretary, J. N. McCormack, Bowling Green.

INDIANA Board of Medical Registration and Examination, Indianapolis, October 23-25. Secretary, W. T. Gott, Indianapolis.

Nebraska May Report.—Dr. George H. Brash, secretary of the Nebraska State Board of Health, reports the written examination, held at Lincoln, May 29-30, 1906. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 49, of whom 36 passed and 13 failed. Twenty-eight reciprocal licenses were granted. The following colleges were represented:

PASSED.

Nineteenth Annual Meeting, held at Cincinnati, Sept. 20-22, 1906.

(Continued from page 1045.)

Peritoneal Adhesions.

DR. ROBERT T. MORRIS, New York City, mentioned as favorite fields for chronic peritoneal adhesions the region of the cecum and appendix, the gall bladder, the sigmoid region, and pelvis. The greatest amount of disturbance calling for attention on the part of the surgeon comes from the region of the gall bladder, because the organs in this region are more movable than those elsewhere, such as the liver and diaphragm, which move with every inspiration and pull on the adhesions and the stomach, which is moving constantly. Next in the order of importance is the group of adhesions in the region of the cecum and appendix. Adhesions in the pelvic region, which, although extremely common, do not call for so much interference on the part of the surgeon as do the other groups of adhesions, for the reason that the viscera involved rest on the pelvic floor, and are subject to such constant and varying degrees of friction. Adhesions about the sigmoid give rise to comparatively little disturbance.

As to treatment. there are certain instances that do not call for much surgical attention. In these cases the minor psychoses should be ruled out. As to the method of treating these cases. he first began by simply separating them. He tried rubbing them with oil for a while, without getting marked results; then he followed the plan of filling the peritoneal cavity with saline solution after operation. But this was not wholly satisfactorily, because the salt solution is absorbed too rapidly.

He then adopted the method of using the aristol film, because he noticed that when raw peritoneal surfaces are exposed to the air there is a tendency for a lymph coagulum to form. An insoluble material like aristol offers a mechanical obstacle to readhesion at that point. The tri-iodid of thymol offers the best mechanical protection. It makes a smooth coagulum with the lymph and remains for a long time. In rabbits it was still present after a year. The Cargile membrane prevents the recurrence of adhesions very regularly, although not completely sometimes. Sometimes the surgeon may have to repeat the operation. Dr. Morris expressed himself as unwilling to state which is the better of the two, the Cargile membrane or the aristol film. Both are distinctly valuable in their proper places.

Porro Cesarean Section for Pregnancy, with Complicating Fibroids.

Dr. James F. Baldwin, of Columbus, Ohio, said statistics show that in cases of pregnancy complicated with fibroids, unless the latter are so small as to be negligible, a maternal mortality of over 30 per cent., and a fetal mortality of probably 50 per cent.. is obtained. Porro Cesarean section, with proper surroundings and competent operator, should give a maternal mortality of only about 5 per cent.. and practically no fetal mortality whatever. Hence this operation should be uniformly advised in this class of cases.

Uterine Fibroids Complicating Pregnancy.

Dr. Marcus Rosenwasser, of Cleveland, Ohio, said the recent report of cases of uterine fibroids obstructing delivery, in which the lives of mother and child were seriously endangered in the effort to deliver by the natural channel, justified operators in reporting the cases relieved by Cesarean section for the purpose of establishing the latter as a safer and better method of saving both lives. The report of a Porro Cesarean section successfully terminated was made as an additional contribution to papers previously read before the association and published in its transactions of 1896 and 1899. In this case the pelvis was obstructed by an immovable subperitoneal fibroid located in the posterior wall of the lower uterine segment. The operation had been planned for the onset of labor at term, but owing to rupture of membranes and prolapse of cord, became an emergency operation at the beginning of the ninth month. Mother and child were saved.

DISCUSSION.

Dr. E. Gustav Zinke, Cincinnati, Ohio, delivered two women in whom tumor was discovered after delivery. The tumors were intramural, very small, one the size of a walnut, the other the size of a hen's egg. The first case he saw was one of interstitial fibroids which implicated the intrauterine wall. It had been in the hands of a midwife, and when she failed to deliver the woman a physician was called in to assist. This was twelve years ago. As it was impossible to effect delivery in the usual manner, Dr. Zinke was called in and did a Cesarean section. The fetus had been dead for some time, and the woman died within forty-eight hours of sepsis. Where pregnancy is far advanced and a fibroid tumor is recognized, it is an extreme source of danger to the woman, especially if the tumor is subperitoneal. He thinks Cesarean section gave the woman as well as the child the best chance for their lives.

Dr. Oscar H. Elbrecht, St. Louis, Mo., mentioned a case of fibroid tumor complicating pregnancy at the fourth month. It was subperitoneal, and situated in the anterior uterine wall. He removed the tumor, and the woman went on to full term.

Dr. Robert T. Morris, New York, operated for the removal of a subperitoneal fibroid at the fifth month of pregnancy in a patient who was having a miscarriage. He operated with a desperate chance of trying to save the child. The patient was nearly 50 years of age, her only pregnancy, and a great deal depended on the birth of the child in the family. The labor pains ceased after he had removed a fibroid about as large as his fist; she went on to full term and was delivered of a living child.

Dr. Edward J. Ill, of Newark, N. J., did not think that every woman who has fibroids ought to have the uterus removed or a Cesarean section done. The indication should be drawn closely. If there is obstruction in labor, then operation is indicated. He has only once done a Cesarean section for fibroids.

Dr. Joseph Price, of Philadelphia, said that these cases, when recognized early, particularly cases of pedunculated fibroids, if they fall into the hands of skilful operators, can be operated on and the fibroids removed, the patients going on to term, and without premature deliveries or abortions.

Dr. Frederick Blume, of Pittsburg, cited a case in which he did a supravaginal hysterectomy for a fibroid tumor complicating pregnancy. He mentioned one case in which there was a tumor an inch above the umbilicus, fluctuating, the size of a three months' pregnancy, and simulating an ovarian cyst. He operated and found that it was the uterus, seven months advanced in pregnancy, and the other was a fibroid tumor projecting into the pelvis. He sewed up the wound and subsequently delivered her of a nine-pound child, but took the liberty of removing the uterus, as she was 45 years of age. It was a breech presentation. The child was dead. The woman, however, got along very well. This case shows that fibroid tumors do not disappear after delivery. In this case the tumor grew in six months to such an extent that it became necessary to do a supravaginal hysterectomy. He does not advocate that any woman who has a fibroid complicating pregnancy should undergo a Cesarean section.

Dr. Hugo O. Pantzer, of Indianapolis, cited a number of cases of fibroid tumors complicating pregnancy. He was called to see the first ten days after the woman had given birth to a child. She had developed fever, and at this time was passing a fibroid which had become gangrenous. In a second instance he was called to deliver a woman who had been in labor forty-eight hours. A large tumor was found located at the fundus, and within four days this tumor sloughed away. In the first case the sloughing fibroid was removed with forceps; the patient made a good recovery, and has since again become pregnant. In the second case the tumor gave evidence of sloughing on the third day after delivery, and within twenty-four hours he operated per vaginam, removed the fibroid, and the woman made a good recovery.

Dr. J. Henry Carstens, of Detroit, Mich., said that if a small fibroid is found in the cervix which causes symptoms, it can be removed per vaginam when the woman is pregnant, which will save her a severe labor. If the fibroid is a large one and situated higher up, and there is likelihood of its interference with labor, the tumor should be removed whether the woman is three or six months pregnant, thus saving her future trouble. If the uterus contains multiple fibroids and there is good reason to suspect considerable trouble on account of their interference with pregnancy, it is well to do either an abdominal or supravaginal hysterectomy, according to the nature of the case. If a Cesarean section is required and there is a very large fibroid to deal with, the fibroid should be removed and the uterus saved.

Abdominal Section for Trauma of Uterus.

Dr. Charles E. Congdon, of Buffalo, N. Y., related a case in which there was puncture of the non-puerperal uterus, with prolapse of the bowel; violent seizure and tearing away of sixteen inches of gut. Abdominal section, with intestinal anastomosis, was resorted to promptly, and the uterine laceration repaired and followed by recovery of the patient.

DISCUSSION.

Dr. Edwin Walker, of Evansville, Ind., reported a case of rupture of the uterus with prolapse of the intestine. The woman had aborted at about the fourth month, and he was called to deliver the placenta. He used the uterine auger, with which he brought away the placenta, and before he realized it he had quite a large mass, which he found to be the intestine. A handful of intestine was presenting at the vulva. Dr. Walker replaced it in the vagina, applied a tight binder, removed the woman to a hospital, opened the abdomen, and found that thirty-one inches, with mesentery, were torn away. He resected the intestine, used a Murphy button, did not employ any sutures in the uterus, as the parts fell together so well, then closed the abdomen, and the patient made a good recovery. He also mentioned a case in which the uterus was punctured during a curettement.

Dr. Rufus B. Hall, of Cincinnati, believes that perforation of the uterus is more frequent than most men are willing to admit, especially in producing abortion. He does not believe that prolapse of the intestine is frequent in perforation of the uterus. He had an experience a few years ago that impressed on his mind forcibly that these cases run in groups. Within eight days he had five patients with perforated uteri who had produced abortions on themselves. These patients were suffering with various stages of infection. All of them were treated, when there was pus present, with vaginal section, and the pus emptied. Three patients recovered and two died.

DR. JAMES F. BALDWIN, of Columbus, related a case of punctured uterus, the result of an attempted abortion. There was an enormous amount of pus discharged through the vagina, and the woman promptly recovered.

DR. WALTER B. DORSETT, of St. Louis, Mo., said the cases of rupture or perforation of the uterus should be classified. If asked to attend a case in which there was perforation of the uterus, produced by an abortionist, he would not hesitate to operate. He has operated on three such cases, cleaning out the pus which was present, and putting in vaginal drainage. He recalled one case of rupture of the uterus in labor in which nothing was done. The intestine was pushed back and the woman made a very good recovery.

DR. JOHN YOUNG BROWN, of St. Louis, said that in spite of the teachings of military surgeons, civil surgeons were beginning to realize the importance of penetrating wounds of the abdomen. It did not matter whether the penetration was caused by the curette, bullet, or by stab wound, the consensus of opinion among civil surgeons is that all such wounds should be explored.

(To be continued.)

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fifteenth Annual Meeting, held in Buffalo, N. Y., Sept. 11-14, 1906.)

(Concluded from page 1047.)

Technic of the Yellow-Fever Campaign.

ASSISTANT SURGEON WILLIAM C. RUCKER, U.S.P.H.&M.-H. Service, who was on duty in New Orleans last year during the yellow-fever epidemic and conducted a campaign against the disease in that place which was successful, although in his labors he contracted the yellow fever himself, described in detail the methods for suppression of an epidemic of yellow fever, which are based entirely on the mosquito dogma.

The three basic principles are that yellow fever is transmitted only by the *Stegomyia calopus* and not *Stegomyia fasciatiæ*, as has been commonly believed; that this mosquito is infected only by biting a yellow-fever patient during the first three days of the disease, and that the mosquito can not transmit the infection until a period of from 12 to 20 days (usually 14) has elapsed. The fundamental object, therefore, of such a campaign is to prevent the breeding of the stegomyia, to locate and to isolate all persons with yellow fever or with suspicious fever as early as possible in the disease to prevent the stegomyia from biting them and thereby becoming infected, and finally to destroy all infected stegomyia.

Stegomyia calopus is a domestic mosquito that breeds around human habitations. Cisterns, rain barrels or places where there is fresh, clean water are the preferred breeding places. In default of such places, however, it may deposit its eggs in foul or stagnant water. The mosquito is sly and persistent in its attacks on the human subject. It bites preferably just above the shoe tops. Only the female bites. The young mosquitoes bite only in daytime, but the adults bite in a darkened room or at night.

Dr. Rucker described in detail the supplies necessary for the attacks on stegomyia in its breeding places, the materials necessary for screening, etc., and the technic of this procedure. The location of those sick with fevers is not easy. The ignorant are prone to hide their sick in order that they may not be sent to the hospital or that their places of business may not be closed, while the better class act in a similar manner to avoid fumigation of their premises and notoriety. It is necessary, therefore, that the people of an infected city be kept under constant surveillance. The main support in all such cases must be the family physician. Cases should be reported early, as a patient is infective to mosquitoes only during the first three days of the disease. During this period the patient should be screened, or in other words, the mosquito should be protected from the patient. After screening the room, fumigation of the room and the surrounding premises is made. The officer should not treat nor offer advice regarding the treatment of patients. The axiom of the service is: "The patient belongs to his physician, the house belongs to the sanitary officer."

The sick are not isolated after the preliminary fumigation; they may receive visitors, but they are protected from mosquitoes. Funerals may be public. Business is not suspended, but places of public congregation are closed at night. Persons entering an infected town are obliged to give their names and city addresses to the division of train inspection. They are then inspected daily for five days. Persons leaving the city should be required to obtain health certificates from the sanitary bureau.

DISCUSSION.

DR. CHARLES P. WERTENBAKER, U.S.P.H.&M-H. Service, New York, said that every military surgeon may at some time be confronted by the problem of suppressing an outbreak of yellow fever, and he will then fully appreciate the detailed information such as has been furnished.

CAPT. S. C. STANTON, Ill.N.G., presented a resolution that copies of Dr. Rucker's paper be sent to the surgeons general of the various services, recommending that the article be distributed as a governmental publication, and that a copy of the resolution be forwarded to the surgeon general U.S.P.H.& M.-H.S. The resolution was unanimously adopted.

Economical Consumptive Sanatoria.

SURGEON PAUL M. CARRINGTON, U.S.P.H.&M.-H. Service, suggested an economical plan for consumptive sanatoria, with description of a new tent house, proposed by himself and tl architect, J. Ross Thomas, of the same service, which was rea in the absence of the authors by Dr. Rucker. The author appreciated the tendency in the past toward constructing ex pensive sanatoria, with costly systems of heating and ventilating, and appreciated also, incidentally, the liability of legislative bodies to make niggardly appropriations for such purposes. For this reason they have evolved a scheme for tent houses, inexpensively constructed, whereby the patient may have sunshine or shadow at any time of day, inside or outside of his room. Each tent is 12 by 14 feet in area, and is intended to house two persons. The ceiling is 9 feet high, and the sides are closed for half that distance. The heat is furnished by a small iron stove. The colony of tent houses has, of course, its administrative building, mess hall, etc., and the authors claim for the scheme, which is now in operation at Fort Stanton, N. M., the advantages of convenience of grouping, flexibility, isolation and economy.

Sanitary Questions in the Navy.

MEDICAL DIRECTOR MANLY H. SIMMONS, U.S.N., in his paper, entitled "The Medical and Sanitary Questions Met in Everday Life on a Cruising Ship in the Navy," pointed out the difference between the soldiers of the old Navy and the new, the great divergence in the duties from the old days, when the sailors were needed to handle sails, and the present time, when machinery is in use for practically all purposes. He spoke of the great difficulty in keeping modern ships in clean and sanitary condition, on account of the complexity of construction, and mentioned the changes desirable from a sanitary point of view, and the manner in which the various emergencies aboard the modern cruising ship have been met.

Resuscitation of Persons Apparently Drowned.

ASSISTANT SURGEON JOHN W. TRASK, U.S.P.H.&M.-H. Service, prepared a paper, read by Dr. Rucker, reporting two cases of prolonged submergence under water in which the patients, after 23 and 30 minutes' submergence, respectively, were resuscitated by continuation of artificial respiration for nearly two hours. From these cases the author urges the practice of persistence in artificial respiration for at least two hours, in all cases of the apparently drowned before hope is abandoned, especially when the known submersion has been less than 30 minutes or when the time of the submersion is in doubt.

Portable Rations for Soldiers.

MAJOR LOUIS LIVINGSTON SEAMAN, U.S.V.E., read a paper on "A Portable Ration for Soldiers in Battle and on the Field," which originally appeared in THE JOURNAL, May 26, 1906, page 1606, and to which he had added a number of observations suggested by his later experiences in Africa, concerning the advisability of an increase in the ration of sugar, and the sustaining properties of the raisin.

DISCUSSION.

Col. W. Grant McPherson, R.A.M.C., took exception to Dr. Seaman's remarks in regard to the absence of enteric disease in the Japanese army. In a recent conversation with a Japanese officer, said he, he had been informed that there were 27,000 cases of dysentery and typhoid fever during the Russo-Japanese war, with 4,000 deaths from enteric fever alone. He did not agree with the optimistic views of the author and objected to the diet suggested, for the reason that in summer it fermented and in winter it froze.

Dr. Harold D. Corbusier, Denver, spoke of the racial characteristics of the components of armies, which must be considered in the diet of all bodies of troops. An army should have a broad diet list on this account. He attached especial value to the use of bacon.

Major W. H. W. Ellicott, Indian Medical Service, gave his experience regarding the diet of troops, especially in the tropics. He considered smoked and jerked meats of great value.

Lieut.-Col. Nathan S. Jarvis, N.G.N.Y., agreed with the essayist in the necessity for sugar in the diet of the soldier, and spoke of his experience while in the United States service, when maple sugar and raisins proved especially valuable to the soldier in long marches over arid plains.

Dr. William C. Rucker, U.S.P.H.&M.-H. Service, stated his belief that diet was only the predisposing factor in the causation of beriberi, but had nothing to do with its causation.

Major Floyd S. Crego, N.G.N.Y., doubted the disappearance of beriberi, which the author claimed, and asserted that the acute symptoms disappeared, but that a modified form remained, which had its manifestation in the neuritis and psychoses, which are fast filling up our asylums, penitentiaries and almshouses.

Entertainment.

The entertainment provided for the association included a reception at the Lafayette Hotel on Tuesday evening, a luncheon given by Dr. Lucien Howe, on behalf of the Buffalo Academy of Medicine, at his residence on Wednesday noon; a reception at the Buffalo Club, of which Dr. Roswell Park is president, on Wednesday evening; an excursion on the United States revenue cutter *Morrill* down the Niagara River to Niagara Falls; a trolley excursion down the Canadian side, returning through the gorge, and a luncheon at Niagara Falls, N. Y. The ladies were given luncheons at the various country clubs, automobile rides, receptions, etc.

BRITISH MEDICAL ASSOCIATION.

Seventy-fourth Annual Meeting, held in Toronto, Ontario, Aug. 21-25, 1906.

(Continued from page 1048.)

SECTION OF SURGERY.

In the introduction, **Sir Hector C. Cameron**, M.D., the chairman, acknowledged the great and daily increasing debt that surgery owes to those on the western side of the Atlantic, and looked forward with keen anticipation to the benefits to accrue from intercourse with the Canadian and American surgeons present.

Prostatectomy.

Dr. George A. Bingham, Toronto, in his introduction of the discussion on prostatectomy gave a description of the microscopic structure of the gland, showing that it lacks a true capsule and that definite lobes are absent. Embryologically, the prostate has been shown to be purely sexual in origin. The pathologic changes in hypertrophy were then taken up to show the relationship of the newly formed tissues to the remainder of the gland. If the modern prostatic enucleation is performed through the outer part of the gland, a portion of the prostate is left behind. In discussion of the treatment, he mentioned three classes of cases: The early cases, where the only symptom is obstruction. In these enucleation is advised with catheter life as an alternative; the very late cases, in which permanent drainage or Bottini's operation is advised; and the intermediate cases, in which enucleation should be performed. The author holds that neither the perineal nor the suprapubic operation meets all indications.

Ascites.

Mr. Sinclair White, F.R.C.S., Sheffield, in introducing the discussion on ascites, stated that ascitic effusion was largely passive and directly due to interference with the passage of blood through the hepatic terminals of the portal vein. Proliferation with subsequent contraction of the tissues forming the framework of the liver is the principal cause of obstruction. It may be supplemented by thrombosis of the portal vein and by defects in the general circulation. In cirrhosis of the liver about 50 per cent. of the cases progress to a fatal issue without ascites, and its absence is explained in these cases by the enlargement of the normal anastomotic vessels connecting the systemic and portal veins and by the development of new anastomoses in adhesions formed between the viscera drained by the portal vein and the abdominal walls. The value of drainage as an adjunct to operations is beyond dispute. Epiplopexy is contraindicated when any of the important viscera of the body are defective. It should in all cases be preceded by one or more tappings. Details of the operation vary, but omental fixation is the most important step. The pathologic changes in the liver are permanent and, therefore, incurable, but the ascitic phenomenon is capable of being arrested and the life of the patient prolonged by the operation.

Duodenal Ulcer.

Dr. William J. Mayo, Rochester, Minn., in his paper, entitled "Surgical Treatment of Ulcer of the Duodenum," declared that in all chronic ulcers of the stomach and duodenum 40 per cent. are situated in the duodenum alone or in connection with the stomach, and that 50 per cent. of all chronic indurated ulcers are also so situated. He then discussed ulcer and its surgical treatment. He thought that gastrojejunostomy has the largest field of usefulness, and excision may sometimes be resorted to.

Acute Septic Peritonitis.

Mr. Charles John Bond, F.R.C.S., Leicester, introduced the discussion on "Acute Septic Peritonitis." He spoke of the great importance of the diaphragmatic portion of the peritoneum and the peculiar sensitiveness of that portion which covers the small intestines. He described the way in which the peritoneum reacts to infection and the protection of the endothelial layer by the formation of a fibrinous deposit. Chemical peritonitis is not seen clinically. Peritonitis accompanying the intraperitoneal extravasation of blood is generally due to the *Staphylococcus albus*. Gonococcal peritonitis is not highly virulent. In ruptured gastric and duodenal ulcer the infection is not highly virulent, but the necessity for immediate operation is most urgent. The infection may frequently be arrested by irrigation, with or without drainage. Septic peritonitis is due to infection from the alimentary canal below the duodenum. The frequent and early migration into the peritoneum of the *Staphylococcus albus* in septic peritonitis, acts beneficially by stimulating the phagocytosis, and has an important bearing on treatment and the question of irrigation.

Peritonitis due to streptococcus infection is highly virulent and generally fatal. Pneumococcal peritonitis is frequent in female children and is present in primary and secondary varieties. The naked-eye observations, the character of the exudate and the appearance of the inflamed membrane are especially important in this variety of the disease. He next discussed the treatment by drugs, morphin and purgatives, by serum and spoke of the urgent need of a polyvalent anti-bacillus coli serum. In considering the surgical treatment, he dwelt especially on the importance of respecting the diaphragmatic area, and the risk of removing phagocytes by indiscriminate irrigation, and stated that the prime object is to attack the primary focus of invasion and arrest further infection.

The next point is the treatment of peritoneal cavity. In cases of moderate severity he considers the safest course to be the treatment of the primary focus by dry sponging or local irrigation and drainage, combined with the least amount of interference with the general cavity, unless collections of fluid exudate in the pelvis or loins require drainage. Highly virulent streptococcal infection may require free irrigation with even partial evisceration. The cases of slight virulence are treated best by free irrigation, either with or without subsequent drainage.

He concludes that irrigation is beneficial where the peritoneum contains foreign material, capable of removal by flushing, but that it is harmful in cases of fibrinous sticky exudate and when used to wash away a turbid exudate containing active phagocytes or when instrumental in spreading infection. Free drainage or tamponade is essential in the treatment of local abscesses, necrosis of the bowel, or when treatment of the primary focus of the invasion must be necessarily incomplete. It is generally harmful in the upper peritoneal area unless this is primarily infected. In the area of the small intestine it is of very little use. It is most frequently used in the lateral areas and in the pelvic basin. The efficiency of peritoneal drainage depends on the integrity of the endothelium in the area drained.

(To be continued.)

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-sixth Annual Meeting, held in Bedford Springs, Sept. 10-13, 1906.

(Continued from page 1049.)

Treatment of Ulcer of the Cornea.

Dr. Edward Stieren, Pittsburg, does not believe that cauterization or stimulation of the ulcer should be thought of in the early stages of a corneal ulcer; and it is a question in his mind whether the employment of eserin or pilocarpin ever preserves an iris from prolapsing into a marginal ulcer, when it perforates and is accompanied with a sudden gush of the aqueous humor. He is also confident that too frequent cleansing of the eye has an untoward effect on the reconstructive process of this delicate structure. His plan of treatment is as follows: First, flushing liberally with saturated boric acid solution; second, filling the sac and keeping the lids covered with bichlorid of mercury ointment, in order to keep the sac as aseptic as possible; third, aiding the cornea in its recuperative process by atrophinizing the eyes, covering them with a cotton dressing, and keeping the patient in a moderately darkened room. Dionin dusted under the lower lid after the eye has been cleansed and before the bichlorid ointment has been used, causes the ulcer to heal more rapidly and renders the patient more comfortable. Indolent ulcers and those showing a tendency to spread are best treated with light applications of tincture of iodin. After using this agent the healed ulcer will show a scar less dense than when stronger chemical agents have been used. Dr. Stieren uses the cautery only in cases of corneal abscess. The liberation of pus caused by the cauterization relieves the excruciating pain usually present. Cases of ulceration of the cornea occurring in gonorrheal ophthalmia or in ophthalmia neonatorum demand especial attention. In such cases it is impossible to obtain even a moderate degree of cleanliness or asepsis of the conjunctival sac. The newer silver salts, although they may not be efficient bactericidal agents, are of value as protective and cleansing agents in gonorrheal ophthalmia. The opacities after their use are less dense than when strong cauterizing agents have been used.

Endogenous Infections.

Dr. Howard F. Hansell, Philadelphia, said that there are two groups of endogenous infections: intestinal intoxication and metabolic autointoxication. Endogenous ocular diseases are those which are caused by a poison created within the body in an organ other than the eye, and conveyed to the eye from the affected organ by means of the circulatory or lymphatic systems. They are distinct and separate diseases from those which involve the eye caused by germs or poisons acquired from sources without the body, or ectogenous diseases. A third class might be made of those which are partly ectogenous and possibly endogenous in causation. A distinction should also be made between autointoxication and metastasis. The former is a lesion induced in a distant organ by an agent created at the original site of the disease; the latter, a conveyance to a distant organ of one or more of the elements that made up the original disease. Endogenous infection of the eye usually starts in the uveal coat, either as a minute thrombosis or as a microscopic collection of bacteria. Next in frequency to the choroid is probably the retina, and finally the vitreous and the aqueous.

New Procedure for Treating a Prolapse of Iris.

Dr. Edward B. Heckel, Pittsburg, said that in a case with simple prolapse of the iris he renders the eye aseptic and instills eserin three times, at intervals of ten minutes. He then waits ten minutes, and then snips off the iris close to the cornea. He uses a horn spatula, shaved down to a millimeter in width, or thereabouts, depending on the size of the corneal wound. He introduces the spatula into the wound, with its long axis parallel to the long axis of the wound; then gives it a slight twist, being careful to allow the iris to withdraw itself gradually from the corneal wound. The lips of the wound will then come close together. A light pressure bandage is then applied. The action of eserin is continued, and the pupil is drawn back to its original position. A good result is secured. Sometimes Dr. Heckel has undertaken the procedure without the use of eserin. The results were sometimes good and sometimes not.

What Is the Safest Operation for Cataract?

Dr. Wendell Reber, Philadelphia, considers that operation the best which insures the greatest safety to the patient. He is convinced that preliminary iridectomy offers the greatest chance of success. So many patients and their family physicians oppose this method, however, that he has made an investigation of the views of the majority of the American operators. He sent circular letters to 160 of these, asking in what conditions they perform preliminary iridectomy, and whether they would do so in a patient who had already lost the sight of one eye. Dr. Reber thinks that one should b governed by the cause of the condition. Those who oppos preliminary iridectomy do so because the cosmetic effect i poorer; it produces more traumatism; the patient's vision i poorer afterward; it requires a longer time to perform; ther is more dazzling afterward; the vitreous is not so well r tained, and it is not justifiable to subject a patient twice t the risk of infection. The argument for extraction wit iridectomy is that it does not require so large an incision capsulotomy is more readily done; delivery of the lens easier; fewer secondary operations are necessary; iris prolap is rare; any glaucomic tendency during the healing may forestalled; there is less confinement to bed, and less hem rhage. The argument against two operations are that th is increased risk in opening the eye twice; one must through the scar tissue of the first operation; patients do care to go through a second operation; the chances of succ are no better with a preliminary operation entailing needl mutilation, and it wastes the patient's time. The author t gives a list of 14 arguments for preliminary iridectomy. Reber thinks that a procedure that facilitates not only diagnosis of cataract, but still more the most important p of the operation on it, seems to merit the preference to o methods. Extraction of cataract is never simpler, easie more durable than when performed on an eye in which iridectomy has been previously made.

Relation of Thyroid and Parathyroid Glands.

Dr. Allen J. Smith, Philadelphia, formulated the fol ing statements: 1. The parathyroids and thyroid glands structurally distinct and are not in any sense interconvert 2. There is probably some relation in their function, and of one seems to stimulate the other into special activity least, into an apparent hypertrophy). 3. The parathy are essential to life, and when lost, are soon followe death, with previous intense symptoms of a neurotic a toxication, which can not be averted by the thyroid i even if practically intact. 4. The loss of the thyroid i lowed by chronic trophic and metabolic disturbances, are not necessarily fatal, and which in general follow the of cretinism, myxedema and chronic cachexia strumipriva man. While the function of the parathyroid strongly suggests its action in an antitoxic manner, there is reason to believe that in the case of the thyroid a metabolic physiologic secretion is produced, although it is possible that in a limited sense here, too, an antitoxic action is associated. 5. It seems probable that the active product of the thyroid is one of the iodin-organic compounds that have been isolated from it, probably the thyroglobin of Oswald. 6. There is suggestive evidence that, in addition to the indefinite relation believed to exist functionally between the thyroid and parathyroids, there is also a close relation held to the thyroid by the hypophysis cerebri, which may have some degree of compensatory ability. 7. In addition to the foregoing, the thyroid also is concerned in the functions of growth; is involved especially in nitrogenous metabolism, and has some indefinite but real influence on the development and efficiency of the generative apparatus.

Etiology of Diseases of Thyroid Gland.

Dr. Theo. J. Elterich, Allegheny, classified diseases of the thyroid under the captions of congestion, inflammation (thyroiditis), neoplasms, simple hypertrophy (goiter), exophthalmic goiter, and cretinism and myxedema. In cretinism the administration of thyroid extract results in a return to growth and development approaching the normal. The therapeutic use of thyroid preparations has not been limited to diseases associated with disturbances of the thyroid gland, but has been extended to quite a large number of conditions that have no association with thyroidal perversion. Indications against the use of thyroid preparations are weakness of the cardiac action, albuminuria or glycosuria, tuberculous disease or a suspicion of grave renal or hepatic disease.

Symptomatology, Diagnosis and Medical Treatment of Exophthalmic Goiter.

Dr. Alfred Stengel, Philadelphia, said that diseases very different from each other are probably now all classed together as exophthalmic goiter, the only distinction now made being between exophthalmic goiter and pseudo-exophthalmic goiter. The latter is sometimes a case in which the system has not the proper resisting power to the thyroid poisoning, and often results from fright at the menstrual period. It is transitory in character, but has some of the symptoms of exophthalmic goiter. In different pathologic conditions there may be hyperthyroidism. The symptoms may be more or less pronounced, nervous symptoms, sometimes very severe, being frequently present. There are also circulatory symptoms, including palpitation, murmurs and sudden flushes of the skin; the thyroid symptom of enlargement of the gland; and the ocular symptoms, including protrusion of the eyes, retraction of the upper lid, a tendency to wink at long intervals, and the staring forward of the eyes. Sometimes there are gastrointestinal symptoms, such as nausea and vomiting, pain in the abdomen and intense emaciation. Exophthalmic goiter is more permanent. The enlargement of the gland is less fluctuating, and in cases that are not exophthalmic, some other symptom is usually more prominent than is the thyroidal condition.

It is impossible to say, in any given case, whether the remedies prescribed or the hygienic regulations attending the giving of the remedies has accomplished the cure. On the other hand, there are some facts leading one to expect useful results from certain kinds of treatment. Electricity and other agents reduce the vascularity of the gland and limit the secretion. Sedatives are used for the nervous manifestations, but they do not have much effect. Cold applications over the thyroid are used from time to time.

Specific treatment is aimed at the hypersecretion of the thyroid gland. The milk of thyroidectomized goats has been used in the treatment, with rather encouraging results, also a substance obtained from this milk.

The *x*-ray has also ben tried with satisfactory results, the gland becoming sclerotic and atrophied. A certain proportion of the cases that might be called exophthalmic goiter will, however, recover in any case; a certain number of the other cases can be reached by the older methods of treatment designed to reduce the circulation in the gland and the glandular activity; but a large proportion of cases can not be reached in such a way. One should then choose between electricity or the *x*-ray and some of the new forms of antithyroidin or the cytolytic serum. If these fail the aid of a surgeon should be invoked.

Relation Between the Thyroid and the Eyes.

Dr. John E. Weeks, New York, drew attention to the fact that diseases of the thyroid and parathyroid are, as yet, inseparable and that in considering the symptoms present in the eye due to thyroid disease, disease of the parathyroid must be induced. He considered the relation of the thyroid to the eye under the following headings:

(1) Conditions of the eye due to pressure of thyroid enlargements; (2) due to local metastasis of malignant thyroid tumors (very rare); (3) due to or associated with absence of thyroid gland; (4) due to compensatory enlargement of the hypophysis cerebri; (5) aggravated by or otherwise associated with goiter—Graves' disease, etc.; (6) due to some form of hyperthyresis.

Oration in Laryngology.

Dr. Ira J. Dunn, Erie, delivered this oration, the first delivered before the society in seven years. He reported the progress made in laryngology and in rhinology during this period.

The Value of Skiagraphy in the Surgery of the Nose.

Drs. W. G. B. Harland and H. K. Pancoast, Philadelphia, believe that *x*-ray pictures are of considerable value in giving a definite idea of the shape, size and location of the accessory sinuses, and in indicating the presence or absence of serious pathologic changes. While more accurate than transillumination, skiagraphy is also influenced by thickness of bone and similar factors, and the pictures should be studied in connection with other means of diagnosis. The secret of success in getting a good picture lies in the use of a hard tube and a diaphragm, with plenty of current and a short exposure. For lateral views the plate is held on the diseased side, the tube being distant about eighteen inches. Exposure should last from twenty-eight to thirty-three seconds, and thirty-two to forty-eight amperes of current should be used. For antero-posterior views the plate is held in front of and close to the face. Clothing is removed from the neck and the tube is held well down. The distance of the tube should be sixteen inches; exposure, ten to twenty seconds; and current, sixty amperes of the primary.

DISCUSSION.

Dr. Weidler asked whether, when the existence of pus is suspected in these sinuses, it is always found there at operation; or whether, just as in transillumination, the presence of pus may be suspected, and none be found on opening the cells. He also inquired whether Dr. Harland had worked out a table of percentage failures in such cases.

Dr. Pyfer said that the skiagraph is very valuable and suggestive, but that the darkening of the cells may mean only a difference in the technic. The plate may be in error, or the conditions may have changed. No one should operate or recommend an operation based on the skiagraphic findings.

Dr. Jackson said that any additional aid in making the diagnosis in these sinus-affections should be welcomed. He referred to the work in skiagraphy done by Dr. Caldwell of New York. The results were beautiful, the difference between the diseased side and the healthy side being very marked. To obtain such results one must not only be skilled in this work, but must also be thoroughly acquainted with the anatomy and pathology of the parts.

Dr. Risley said that skiagraphy probably would have proved useful in a number of his own cases, in which there was sinus-disease associated with protrusion of the eyeball. In two cases there was no apparent reason for suspecting frontal-sinus disease. The eyeball was pushed very far forward, there was violent pain, optic neuritis was present, and the vision was down to one-fifth. In one of these cases, operation disclosed an enormous pus-pocket back of the eyeball, the ethmoidal sinus practically being gone. Dr. Risley did not suspect the existence of such disease; it was only the condition of the middle turbinated, which he was about to amputate, that led him to discover the trouble with the ethmoidal sinus.

Intranasal Conditions Bearing on the Etiology of Ear Diseases.

Dr. G. Hudson Makuen, Philadelphia, classified the intranasal conditions giving rise to ear complications as follows: (1) Those causing disturbances of nasal respiration; (2) those attended by suppurative intranasal and sinus inflammation, and (3) any condition which by pressure or otherwise may give rise to reflex disturbances. The first class includes hypertrophic and atrophic rhinitis, intranasal growths, septal deflections and spurs, and naso-pharyngeal hypertrophies and tumors; and the damage to the ear is chiefly mechanical in its origin. The second class includes all catarrhal conditions of the nasal and accessory cavities; and the damage to the ear is usually by continuity of structure. The third class includes those conditions which give rise to irritation of the terminal nerves in the nasal and accessory cavities, and set up ear complications by so-called reflex action.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Typhoid Fever.

In an abstract in the *Pract. Med.* series Le Fevre states that the ideal diet for typhoid patients should be: 1, Liquid; 2, easily digested; 3, easily absorbed; 4, without solid residue; 5, not easily putrefiable; 6, should contain the requisite ingredients in normal proportions; 7, should be palatable. He states that milk alone does not fulfill these conditions or does so rather imperfectly. He recommends not more than two pints of milk daily, but adds carbohydrates, egg albumin, gelatin, especially in soups. He mentions the fact that gelatin obtained from soup stock is not only a nutriment, but is also a preventer of hemorrhages. This preparation, according to Harbin, serves three purposes: 1. It adds to the relish of various liquids. 2. It lessens nitrogenous waste from the system. 3. It prevents hemorrhage. He recommends a teaspoonful three times a day. Billings states that the effects of gelatin as a nutriment and as a hemostatic may be questioned. It is probable that gelatin which does not contain calcium chlorid will not increase the coagulation of the blood. It has not high nutritive value. In addition to other food preparations as a seasoning substance it may serve a good purpose. McCormick, in the same publication, gives the following outline of treatment of typhoid fever patients: The patient should first be given a bath for cleanliness, and an initial dose of calomel to move the bowels. Guaiacol is then recommended in emulsion or in capsules, in two-minim doses (.12) every two hours. This may be combined as follows:

℞.	Guaiacol	ʒi	4
	Eucalyptol	ʒii	8

M. Ft. capsules No. xxx. Sig.: One capsule every two hours.

If this capsule is not well borne, he recommends that guaiacol carbonate be substituted, given in three-grain doses every two hours.

The bowels should be kept thoroughly open at first with calomel, followed by magnesium sulphate, sodium sulphate or other laxatives similar to the following:

℞.	Podophyllin	gr. 1/8	008
	Massæ hydrargyri		
	Thymol, āā	gr. i	06

M. Ft. capsula No. i. Sig.: One such capsule every three hours until bowels move.

The colon should be well washed out once daily with a normal saline solution; if the temperature is 102.5 F. or higher this enema should be given cold; if below that degree it should be given lukewarm. To relieve tympanites he recommends turpentine emulsion in five-minim doses (.30).

Highsmith advises the following to relieve tympanites.

℞.	Hydrarg. chlorid mitis		
	Pulv. ipecacuanhæ		
	Pulv. opii		
	Pilocarpinæ muriatis, āā	gr. i	06

M. Ft. chartulæ No. xx. Sig.: Take one every hour.

DIARRHEA.

O'Connor states that diarrhea is due to the patient being unable to digest milk, and beef tea also increases the tendency to diarrhea. When diarrhea is present barley water should be added or lime water, and, if necessary, peptonized milk with lime water should be given; beef tea should be stopped and mutton broth added in its stead. If the stools are offensive, small doses of calomel may be added.

CONSTIPATION.

This may be correctel by increasing the broths and reducing the milk.

HEMORRHAGE.

The stools should be constantly examined for evidences of blood. Sometimes sloughs may be found antecedent to the hemorrhages, when turpentine may be given and the diet regulated. When hemorrhage is present he recommends administration of opium and turpentine, a reduction of the stimulants as much as possible and the administration of calcium chlorid

Yeo states that in cases of hemorrhage the intestinal movements must be arrested and in some cases this inactivity must be prolonged for 14 days in order to avoid the danger of a recurrence, and then to produce a movement by an enema of olive oil. On the occurrence of hemorrhage he recommends the following enema:

℞.	Pulv. opii et ipecac.	gr. v	30
	Acidi tannici	gr. x	65
	Mucil. acaciæ	℥i	30

M. Sig.: This amount to be combined with one or two ounces of warm water, arrow-root water or a thin starch solution and introduced into the bowel through a long rectal tube (8 to 10 inches long). In case of children the amount of Dover's powder must be proportionately reduced.

By the mouth the following combination is recommended·

℞.	Acidi gallici	gr. lx	4
	Alcoholis	f℥i	30
	Solve et adde		
	Acidi sulphurici arom.	fʒi	4
	Glycerini	ʒiii	12
	Liq. opii sedatavi (B. P.)	m. xv	1
	Aquæ cinnamomi q. s. ad	f℥vi	180

M. Sig.: Two tablespoonfuls every hour for six doses and then every three hours.

HEADACHE.

For the relief of the headache which so constantly accompanies typhoid fever, O'Connor recommends antipyrin in moderate size doses or sodium salicylate with mustard applied locally to the nape of the neck. He speaks of severe headache as indicating a liability to hemorrhage.

McDowell, in the *Dublin Jour. of Med. Sciences*, recommends in the earlier stages of the disease that a mixture containing dilute hydrochloric acid be given, and as the disease progresses he advises the following combination:

℞.	Quin. sulphatis	ʒss	2
	Acidi citrici	fʒiiss	10
	Aquæ q. s. ad.	f℥iv	120

And:

℞.	Ammon. carb.	gr. lxxx	5
	Tinct. senegæ	fʒiiss	10
	Sodii bicarb.	ʒiiss	10
	Tinct. digitalis	gtt. lxxx	5
	Aquæ q. s. ad	f℥vi	180

M. Sig.: Two teaspoonfuls combined with one-half teaspoonful of the alkaline mixture and half a teaspoonful of water in effervescence every three or four hours.

If the patient's heart is weak and a cardiac tonic is indicated, the following combination is recommended:

R. Tinct. strophanthi	fʒi	4	
Liq. strychniæ (1 per cent.)	fʒss	2	
Aquæ dest. q. s. ad	f℥iii	90	

M. Sig.: One teaspoonful as necessary.

To relieve the severe headache and the pains throughout the body the following combination is recommended by McDowell as a very efficient one:

R. Sodii salicylatis			
Kalii nitratis, āā	gr. x		65
Tinct. gelsemii	m. v		30
Aquæ q. s. ad	f℥ss	15	

M. Sig.: To be taken at one dose.

To check hemorrhage the following combination is recommended:

R. Tinct. camph. co	fʒss	2	
Acidi sulph. arom	m. x-xx		65-1.20
Spts. chloroformi	m. x		65
Syr. zingiberis	fʒi	4	
Decoct. hematoxyli q. s. ad	f℥ss	15	

M. Sig.: This amount to be taken at one dose and repeated after every bowel movement, diminishing the amount as soon as the hemorrhage seems to be under control.

To relieve the persistent vomiting he recommends a mustard leaf to the epigastrium and the following combination in half-ounce doses every four hours:

R. Bismuthi subnitratis	gr. viiss		50
Potassii nitratis	gr. ii		12
Liq. morph. hydrochlor. (1 p. c.)	m. viiss		50
Acidi hydrocyan dil	m. iiss		15
Pulv. tragacanthæ co.	gr. viii		50
Aquæ q. s. ad	f℥	15	

M. Sig.: To be taken at one dose.

The first dose should be preceded by half a teaspoonful of dilute hydrochloric acid. In case of failure he advises nutritive enemata, administering the mixture at intervals to test the irritability of the stomach.

Diarrhea is checked, according to McDowell, by stopping all nitrogenous foods, peptonizing all milk and administering one of the following combinations:

R. Tinct. camph. co.			
Acidi sulph. arom.	fʒss	2	
Spts. chloroformi.	m. xv	1	
Aquæ q. s. ad	m. x		65
	f℥ss	15	

M. Sig.: To be taken at one dose and repeated as necessary. Or:

R. Tinct. camph. co.			
Sodii bicarb.	fʒss	2	
Pulv. cretæ co	gr. v		30
Tinct. opii	gr. xx	1	20
Spts. chloroformi	m. v		30
Sodii salicylatis	m. x		65
Pulv. tragacanthæ co., āā			
Aquæ q. s. ad	gr. x		65
	f℥i	30	

M. Sig.: At one dose.

Moore regards the salicylate of quinin as superior to salol or any other intestinal antiseptic.

Turpentine is regarded by some authorities as the best general remedy in typhoid fever. It may be given in capsules in from 5 to 10-minim doses (.30-.65) or combined as follows:

R. Spts. terebinthinæ			
Spts. etheris nitrosi			
Spts. chloroformi, āā			
Syrupi amygdalæ q. s. ad	fʒi	4	
	f℥iii	90	

M. Sig.: Shake the bottle well and take one tablespoonful at a dose. Or:

R. Spts. terebinthinæ			
Tinct. lavendulæ co., āā			
Sacchari	fʒiss	6	
Pulv. acaciæ	ʒiss	6	
Aquæ q. s. ad	ʒii	8	
	f℥iii	90	

M. Sig.: Two teaspoonfuls every three or four hours.

NERVOUS SYMPTOMS.

Nervous symptoms are best treated by hydrotherapy, such as the ice pack or ice cap. The following combination may have to be employed to allay the nervous manifestations:

R. Strontii bromidi			
Sodii bromidi, āā	ʒvi	24	
Aquæ menth. pip. q. s. ad	f℥iii	90	

M. Sig.: One tablespoonful every three hours in water. Or:

R. Ext. opii	gr. iii		20
Asafetidæ	ʒss	2	
Ext. hyoscyami	gr. iii		20
Olei theobrom. q. s.			

M. Ft. suppos. No. vi. Sig.: One suppository every four hours.

Medicolegal

Rights of State Boards to Revoke Licenses.

The Supreme Court of Indiana holds, in Spurgeon and others vs. Rhodes, that it was error to grant a temporary injunction, on the application of the latter-named party, restraining the members of the State Board of Medical Registration and Examination from proceeding to hear and determine charges of "gross immorality" pending against him before said board and from revoking his license to practice medicine. It says, among other things, that the allegation in the complaint to the effect that a certain-named woman was employed to procure evidence in regard to his character was not denied, but this alone would not authorize the granting of a temporary injunction. The gist of the complaint was that the defendants had prejudged his case and had intended to revoke his license without any evidence and without giving him a hearing. The affidavits of five members of the board and their attorneys denied the charge, and said in effect that they intended to and would give him a fair and impartial hearing, and would determine the charges according to the evidence. This was all that he was entitled to demand. The fact that the woman mentioned was not in the state and could not be compelled to attend the hearing of the charges, or that the board would try the charges without her presence or testimony, furnished no ground for enjoining the board from hearing and determining the truth of the charges.

It was insisted that the temporary injunction was properly granted for the reason that section 7322 of Burns' Annotated Statutes of Indiana of 1901, under which the charges in question were presented to the board, so far as it attempted to confer on the board the power to try complainant and determine whether or not he was guilty or not of the gross immorality charged, and to revoke or refuse to revoke his license therefore, was wholly unconstitutional and void, in that it attempted to confer on the board such judicial power; that it was in violation of the fifth amendment of the Constitution of the United States, which provides that "no person shall be held to answer for a capital or other infamous crime unless on a presentment or indictment by a grand jury," and of the sixth amendment, which provides that "in all criminal prosecutions the accused shall enjoy the right . . . to have compulsory process for obtaining witnesses in his favor"; and that it violated the provision of said Constitution that "the trial of all crimes except in cases of impeachment shall be by jury." But the court says that these provisions apply only to proceedings and prosecutions in the courts of the United States and laws enacted by Congress; not to laws enacted by the legislatures of the states.

Statutes prescribing the qualifications of practitioners of medicine and surgery, and otherwise regulating the practice of those professions have been uniformly upheld by the courts as a valid exercise of the police power of the states, infringing no provisions of either federal or state constitutions. Statutes containing a provision like the one in question here, authorizing the board to revoke a license when the holder has been guilty of a felony or of gross immorality, have been held not to violate any provision of the federal or state constitutions, and it has been held that the granting or refusing to grant a license to practice medicine, or the revocation thereof by the board, is not the exercise of judicial power.

Physician Can Not Recover for Street Railway's Damage.

The Supreme Judicial Court of Maine says, in the case of Parsons vs. the Waterville & Oakland Street Railway, an action brought by a physician, that the fact that the plaintiff was hindered, delayed, and inconvenienced, and people desiring to consult him professionally were kept away, because of having to cross the defendant's track, would not give him a right of action against the defendant for a lawful use of the public way. The use of a street by a street railroad is a public servitude imposing no additional burden on the abutter.

Exhibiting Person With Explanations by Physician.

The Kansas City Court of Appeals says, in the personal injury case of Houston vs. Chicago, Rock Island & Pacific Railway Co., where the plaintiff was thrown down, striking his back on an iron coupling, that he was permitted, during the trial, to remove his clothing from the part of his body said to be affected by the injury while a physician stated where the nerve or nerves were located and the course of their location. The court does not discover any error in so doing, or any harm which could result to the defendant therefrom.

Son Not Necessarily Employed—Power of Local Surgeon.

The Court of Civil Appeals of Texas says, in Galveston, Harrisburg and San Antonio Railway Co. vs. Allen, brought by two physicians, father and son, to recover for medical services, that, while it may be that "necessity knows no law," it is certain that the law knows no necessity for a young physician being regarded as employed in a case of surgery because of the employment of his father. It also says that it can no more be said that it is within the scope of the apparent authority of a local surgeon of a railway to employ another surgeon to do his duty than it can be said that it is in the apparent scope of a station agent's authority to employ another man as a station agent to perform the duties intrusted him.

Contagious Disease Hospital Not Deemed a Nuisance.

The Court of Chancery of New Jersey says, in the case of State, on the relation of the Board of Health of Hamilton Township, vs. the Inhabitants of the City of Trenton, that a building used as a hospital for the treatment of diseases contagious and infectious in their nature is not per se a nuisance, and the erection and use of such a building will not be restrained simply because there is an apprehension that it may result in being a nuisance; but the court must be satisfied that there is a well-grounded apprehension.

Waiver of Privilege Under Statute—Cross-Examination.

The Supreme Court of Idaho says, in the case of Trull vs. the Modern Woodmen of America, that section 5958 of the Revised Statutes of that state of 1887 contains the following provision: "There are particular relations in which it is the policy of the law to encourage confidence and to preserve it inviolate; therefore, a person can not be examined as a witness in the following cases: . . . 4. A physician or surgeon can not, without the consent of his patient, be examined in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient." This provision of the Idaho statute is to be found in the statutes of many of the states, and especially in California, New York, and Missouri. It has been uniformly held that such a statutory provision disqualifies a physician from testifying concerning any facts learned by him or disclosures made to him in the course of his professional treatment of or attendance on a patient. It has also been held that the privilege accorded the patient by such a statute is a personal privilege and can not be waived for him by any other person, and that the death of the patient makes a waiver impossible, and that the physician can never thereafter be permitted to testify concerning any matter touching his professional employment during the life of the patient. On this point, however, there is great diversity of opinion.

More particularly, the court holds in this case that, where, in an application for life insurance the applicant stipulates and agrees that he waives all provisions of law preventing a physician from testifying as to any information acquired by him while attending his patient or rendering him incompetent as a witness as provided in section 5958 above quoted, such waiver is valid and entitles the beneficiary named in the policy, as well as the insurer, in an action on a policy issued on such application, to call and examine the physician who attended the insured during his last sickness, and have him answer questions which, but for such waiver would be regarded as privileged communications that the witness could not disclose. Since the statute authorizes the patient to waive the privilege of secrecy imposed on his physician, and does not fix any specific time at which such waiver can or must be made, no reason is discovered why the waiver may not equally as well be made by contract and in advance of the relation of physician and patient arising as at the time of the trial. As to whether or not the privilege of secrecy granted by statute is a personal privilege attaching only to the person of the patient or can be waived by his heir or legal representative is a question left, so far as this court is concerned, undecided.

The court finds no error in a physician being permitted to be asked on cross-examination the question: "If a man died of the disease supposed to be smallpox, and the man who nursed him all that time had never been vaccinated, and did not take the smallpox at all from the patient, would you think it smallpox?" The rule, it says, is liberal in allowing a broad range of inquiry on cross-examination, and this rule is especially and particularly applicable when it comes to the cross-examination of that class of witnesses commonly called "experts."

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

September 22.

1 *Obstruction of the Common Bile Duct. J. F. Erdmann, New York.
2 *Lupulin in the Treatment of Gastrointestinal Diseases. H. Stern, New York.
3 Some of the Factors that Predispose to Phthisis. L. P. Barbour, Boulder, Colo.
4 Tuberculous Peritonitis. J. B. Boucher, Hartford, Conn.
5 *An Urgent Plea for the Use of Larger Doses of Antitetanic Serum for Lockjaw. R. Engelmann, Chicago.
6 *Dipsomania. C. J. Douglas, Boston.

1. **Obstruction of Common Bile Duct.**—Erdmann says that when all medical aid has been given without result, or if the symptoms are so urgent as to demand immediate surgical interference, the condition narrows itself to a question of surgical technic and after treatment. In exposing the duct Erdmann makes the incision over the right rectus muscle, splitting the fibers in the middle and internal, or middle and external thirds, for a distance sufficiently long to explore the duct. If the stone is located or adhesions demand it, the incision is rapidly enlarged to give ample working room. After the stone is removed, a fish-tail rubber tube, with from one to three openings, and from 10 to 12 inches long, is passed into the duct in its proximal direction for its lower three-quarters of an inch, sufficiently to bury the apertures only. The tube is held in place by a suture of chromic catgut.

2. **Lupulin in Gastrointestinal Diseases.**—Stern has found lupulin of special value in the functional disturbances of the stomach, in sensory as well as motor and secretory neuroses, and in neurasthenia gastrica. Lupulin may also be employed with advantage in diseases of the stomach, with an anatomic basis. As in gastric diseases, so in relation to the intestines, lupulin is particularly useful in the treatment of neuroses and functional disorders. In intestinal diseases with an anatomic basis, lupulin is often a symptomatic and sometimes a curative remedy. Stern claims that the use of this drug for protracted periods is never followed by undesirable after effects, which are so common with many remedies employed for similar purposes. He thinks that it is probable that enteric fever, as well as dysentery, will be favorably influenced by it.

5. **Use of Larger Doses of Antitetanic Serum.**—Engelmann believes that the ineffectiveness of antitetanic serum in cases of tetanus is due to insufficient doses. In one case, the his-

tory of which she reports, she administered the serum by both intraspinal and subcutaneous injections to the amount of from 60 c.c. to 80 c.c. daily to begin with, the total amount given being 650 c.c. subdurally, and 45 c.c. directly into the wound. After five days of this treatment the man was comfortable, with flaccid muscles and less rigid jaw. Recovery took place in four weeks and at the end of six weeks the patient was back at work.

6. Dipsomania.—Douglas defines dipsomania as an abnormal demand of the nervous system, either constant or periodic, for the drug action of alcohol—a demand so strong that the patient takes the alcohol in spite of his earnest wish and effort to avoid it. Dipsomania partakes of the nature of both a neurosis and a psychosis, the predisposing cause being a nervous system that is peculiarly susceptible to the poisonous or intoxicating action of alcohol. Dipsomania is a curable disease and not a mere habit. The patient should be removed from home, with all its customary surroundings, and devote himself to the business of being cured. In the majority of cases Douglas administers some remedies hypodermically at stated hours. He usually prescribes alcoholic liquors during the first few days of treatment, gradually withdrawing them. Milk and raw eggs are probably the best nutriment. He finds that apomorphin is the most prompt and effective hypnotic.

7 Two Cases of Lymphatic Leukemia. J. L. Whitney, Branford, Conn.
8 Trachoma. B. P. Croft, Greenfield, Mass.
9 *Winter Climate of Tucson, Arizona. I. W. Brewer, Fort Huachuca, Ariz.
10 *Removal of an Enormous Ovarian Tumor. W. A. Smith, Springfield, Mass.

9. Winter Climate in Tucson.—Brewer recommends residence in Tucson during the winter to consumptives. The town itself is all that can be desired for residence purposes, he states, both as to its surroundings and social advantages. The temperature from October to March is ideal. Only 6 per cent. of the days are cloudy, and rain falls on an average of only 19 days. There are occasional dust storms. Tucson is a desirable winter resort for persons in the early stages of tuberculosis, but not for advanced cases.

10. Enormous Ovarian Tumor.—The tumor removed by Smith weighed 192 pounds. The patient was 42 years of age and had been ill for two or three years. She had been under treatment by a quack for nearly two years, electricity being used in the treatment, but the tumor continued to increase in size. The cyst wall was adherent over the entire front of the abdomen, covering a space of about three square feet, extending to the diaphragm, and involving a portion of it. Beneath the liver was a mass the size of a child's head, consisting of several small cysts. The pedicle was about half an inch in diameter. The patient died 24 hours after the operation from general exhaustion and shock.

18 Danger of Weak Solutions of Carbolic Acid when Used in Surgical Dressings. A Plea for Restricting Their Sale. L. B. Meyer, New York.
19 Case of Angioneurotic Edema. H. Morgenbesser, New York.

11. Prostatectomy.—Guiteras reviews the improvements made in the operation of prostatectomy by American surgeons and devotes considerable space to discussing the relative merits of the perineal and suprapubic operations. He favors the latter, although he believes that certain prostates can be removed more easily and safely by the perineal route. He says that suprapubic prostatectomy holds the same relation to the perineal operation that abdominal hysterectomy does to the vaginal, in that it is a better surgical procedure; that the changing of the patient's position simplifies the different steps of the operation; and that in most cases suprapubic prostatectomy is preferable to the perineal on account of the ultimate operative results, the purposes for which the operation is performed.

12. Cholcystostomy.—As a substitute for Robson's methods, which he deems faulty, Crouse offers a surgical procedure for which he claims the following advantages: 1. It permits the delivery of the fundus of the gall bladder through the entire abdominal wall, unless the patient is inordinately fleshy. 2. Pericholecystitis frequently binds not alone the gall bladder into a constricted position, but drags on the S-curved cystic duct to the extent of at times inducing all the simulating symptoms of calculi and furthering their cystic development. The method above described removes such restrictions. straightens out the cystic duct, thus favoring more perfect drainage not alone of the cystic, but of common and hepatic ducts as well. 3. It liberates the gall bladder from the usual strain of respiratorily induced hepatic movements, fruitful sources of subsequent pains. 4. The gall bladder's new position does not lay the patient liable to hernial development between liver and gall bladder, owing to the usual anatomic restraint of mesocolon attachments of duodenal hepatic ligament and gastric position. 5. It permits surgical cleanliness, digital exploration and immediate drain of gall bladder. 6. A perfect approximation between gall bladder and parietal surfaces is permitted. 7. It permits all surgical steps to be made safely at one sitting, gives a thoroughness and completeness to the operation not experienced while following the Robson methods.

13. Treatment of Biliary Affections.—A member of his own family having had a biliary fistula during the last five years, Herrmann had an unusual opportunity of observing the effect which the ingestion of food had on the relative quantity of bile which flowed into the duodenum by way of the common bile duct, and the amount, which flowed into the cystic duct and out through the fistula. Several facts were noted. First, the amount of fistulous bile was greater during the night than during the day, in the proportion of about two to one. Second, when a meal was taken late at night there was very much less fistulous bile, the daily amount of bile secreted remaining approximately the same. These facts indicated that the ingestion of food had a decided effect on the amount of bile which passed into the duodenum. It was further noted that fruit and other substances which increased intestinal peristalsis, also diminished the amount of fistulous bile. Alcohol seemed to act unfavorably by increasing the amount which escaped. The regular habit of tea drinking gave a disagreeable odor to the bile. If the last meal is taken at 7 o'clock in the evening, at 11 o'clock it has usually passed entirely into the small intestine, and from that time until 7 o'clock the following morning the bile secreted is for the most part stored up in the gall bladder, or if there is a fistula, the greater part escapes through that opening. If a meal is taken at 11 or 12 o'clock, its digestion requires two or three hours; during this time bile flows into the duodenum, and so much less escapes through the fistula. During the day the intervals between meals are shorter, so that there is less bile stored in the gall bladder, and therefore less escapes through the fistula. By adding a small meal at night, Herrmann succeeded in reducing the amount of fistulous bile from 26 to 6 grams.

These results prompted him to employ a similar method in the treatment of catarhal jaundice. The result was a most gratifying one. The treatment consists in giving five or six small meals instead of the usual three daily, an extra one being introduced at 10 o'clock in the morning, at 4 o'clock in the afternoon, and at 11 o'clock at night. These small meals consist of milk, eggs, broth, crackers or bread. If the patient awakes during the night a glass of milk may be taken. The bowels are to be kept open by mild laxatives. A daily rectal injection of cold water is sometimes very efficacious. Light exercises, especially such as bring into play the diaphragm and the abdominal muscles, are helpful.

36. Conservatism in Gonorrheal Diseases of Uterine Appendages.—Sanes makes a plea for the conservative treatment of gonorrheal diseases of the uterine appendages, basing his remarks on 195 cases studied by him. Of this number 160 patients, or 82 per cent., were found to be below 30 years of age. Ninety-eight, or 50 per cent., had never been pregnant. Twenty-three, or 11 per cent., had aborted but had no children; fifty-seven, or 29 per cent., had only one child each, making a total of 90 per cent. of the patients each of whom naturally would be anxious to preserve her reproductive function. Sanes states that cases of gonorrheal salpingitis are often cured spontaneously by expectant treatment, some recovering spontaneously even after they develop into pus tubes. He cited a number of instances in which pregnancy took place, followed by the birth of a living child. For a pyosalpinx in its early stages, with the gonococci still active, if an operation is necessary, a vaginal salpingotomy and drainage is, to his mind, the best operative procedure. Abdominal conservative operation at this stage is dangerous. A sterile hydrosalpinx demands a salpingostomy, vaginal or abdominal. For a single sterile pyosalpinx it has been his practice to perform a salpingectomy, vaginal or abdominal. In double sterile pyosalpinx, the patient being young and anxious to preserve her sexual functions, a vaginal salpingostomy with drainage in the better tube is performed. A chronic pyosalpinx of long standing could hardly be expected ever to resume its function if saved, but even in such a tube, Sanes says, conservatism (vaginal salpingotomy) is often of value as a life-saving measure in patients whose general condition does not permit a radical operation. A secondary operation may be necessary later, but not always. With properly applied and repeated pelvic packing we can obliterate the pus sacs by allowing connective tissue formation, and while the tube then is useless it is also harmless, and the patient is saved from the more radical operation. Should complete salpingectomy be absolutely necessary, the ovaries, or part of them, should be preserved for the purpose of menstruation and possible ovarian secretion. To save part of the ovary involved in tubo-ovarian abscesses is neither safe nor advisable. In cases of double tubo-ovarian abscesses, therefore, no conservatism whatever is possible; but in the 141 patients operated on Sanes found only 7, or 5 per cent., of double tubo-ovarian abscesses, leaving 94 per cent. of patients in whom an attempt should be made to save at least a part of one ovary.

The number of conservative operations performed by Sanes for gonorrheal diseases of adnexa is 72. All the patients were discharged from the hospital as cured, there being no deaths. The postoperative histories could be followed up only in 34 cases. Of these 34 patients 9, or 26 per cent., had a secondary operation, 4 following vaginal drainage and 5 following unilateral salpingo-oöphorectomy. In the 5 secondary operations that followed unilateral salpingo-oöphorectomy no pus was found in any one of them. Two were found to be hydrosalpinx, 2 were normal, 1 was a pachysalpingitis. Four ovarian cysts found in connection with the first 4 tubes necessitated the 4 secondary salpingo-oöphorectomies. Thirty-three, or 97 per cent., retained their menstrual function. One patient, or 3 per cent., lost it in spite of the conservative treatment of the ovaries.

Of the 25 patients not reoperated on, 7 show adnexa palpable though not tender; and of these 7, 3 complain of occasional pain in the region of the palpable tubes. Three, or 9 per cent., conceived; one three years after a unilateral salpingo-oöphorectomy came to the office with pregnancy of three months' standing. One after a salpingo-oöphorectomy seven years ago miscarried twice, and one, the most remarkable of all, gave birth to a healthy child without any complications after a right salpingo-oöphorectomy, left salpingectomy, and partial excision of the left ovary.

Northwest Medicine, Seattle, Wash.

42 *One Hundred and Seventy-Seven Cases of Typhoid Fever Treated in Alaska. E. M. Rininger, Seattle, Wash.
43 Acute Contagious Diseases of Childhood: Duration of Danger of Contagion and Methods of Disinfection. H. G. Lazelle, Seattle, Wash.
44 Sources of Infection and Manner of Contagion of Acute Contagious Diseases of Childhood. W. N. Hunt, Bellingham, Wash.

41. Phosphatic Calculi Following Suprapubic Prostatectomy.—In the case reported by Walker the bladder wound closed entirely in about six weeks, and the patient's condition was all that could be desired for about three months, when he began to notice that when urinating the urine would cease to flow suddenly and there was pain with pyuria. On examination with a sound a calculus could be felt. The lithotrite failing to crush the stone, the bladder was opened and two stones were removed. No cause for their formation was discovered.

42. Typhoid in Alaska.—During seven years of practice in Alaska Rininger treated 127 cases of typhoid. Of this number 13 occurred in females and 164 in males, the age ranging from 14 months to 66 years. The largest number of cases occurred in the third decade. Twelve patients had had the disease previously. Intestinal hemorrhage occurred in 10 cases. Fifteen patients developed venous thrombosis. In 12 cases the left leg was affected, in 2 cases the right, and in one case both legs were involved. Thrombosis of the left popliteal artery occurred in one case. This was followed by gangrene, necessitating amputation of the leg. Neuritis occurred in one case, affecting both feet. Severe nephritis occurred in one case, a man, aged 66 years. This patient died of uremic coma. Subacute osteomyelitis occurred in three cases, attacking the sixth rib at the costo-cartilaginous junction in each case. Orchitis and epididymitis developed in one case. Intestinal perforation occurred in three cases, two of which resulted fatally. There were four cases of relapse. No routine method of treatment was employed. There were only seven deaths in this series.

50 Objective Tinnitus. C. Friedmann.
51 Four Fatal Cases After Purulent Otitis. Hoelscher, Ulm, Germany.

45. **Bier's Hyperemic Treatment of Mastoiditis.**—Kopetzky summarizes his observations of the Bier method for the treatment of acute otitis media, either with or without mastoiditis, as follows: 1. If used early it will greatly increase the probabilities of curing the condition without resort to major operative measures. 2. In cases cured under its influence the reestablishment of ear function will occur quicker than under the usual line of treatment. 3. Its use by the inexperienced is absolutely dangerous. 4. Its employment should be limited to the young and the otherwise healthy. 5. Finally, when the indications are kept in mind and when properly and intelligently used, induced hyperemia will be found a measure destined, when its scope and limitations are better understood, to find a permanent place in otologic therapeutics.

47. **Congestive Hyperemia in Purulent Otitis.**—Kempler reports the excellent results obtained in the treatment of 10 cases by Bier's method and warmly recommends its employment.

52 Some Questions Concerning the Treatment of Uterine Fibromyomata. H. S. Crossen, St. Louis.
53 *Suprapubic Cystotomy as a Preliminary to, and as a Route for the Performance of a Considerable Number of Prostatectomies. W. T. Elam, St. Joseph.
54 Intestinal Autointoxication. J. B. Norman, California, Mo.
55 Etiology of Accessory Sinus Disease. F. C. Ewing, St. Louis.
56 Diagnosis of Inflammatory Diseases of the Accessory Sinuses of the Nose. G. Sluder, St. Louis.
57 Treatment of Diseases of the Accessory Sinuses. M. A. Goldstein, St. Louis.
58 Ocular Signs and Complications of Accessory Sinus Disease. J. Green, Jr., St. Louis.

53. **Suprapubic Cystotomy Preliminary to Prostatectomies.**—Elam does not claim that the suprapubic is the easier route or even the one of choice for the performance of the larger number of prostatectomies. In many cases, however, the immediate demand is for drainage and vesical rest, and Elam prefers the suprapubic route for this purpose. If conditions are favorable the prostatectomy can be performed at the same time, although he has found but few patients whose interests are not better safeguarded by deferring the prostatectomy until a later date, at which time it can be performed by the route which seems best adapted to the character of the growth. The plea in this paper is for conservatism in the effort to prolong life in the case of the advanced and extreme prostatic.

Interstate Medical Journal, St. Louis, Mo.

September.

60 Case of Double Resection for the Correction of Protrusion of the Lower Jaw. V. P. Blair, St. Louis.
61 When Should We Operate in Appendicitis? R. Hill, St. Louis.
62 Urethrotomy for Ruptured Urethra. R. Harrison, London, England.
63 Angioma of the Upper Lid: Operation. J. W. Charles, St. Louis.

59. **Value of Surgical Procedures for Relief of Paralyses Following Acute Anterior Poliomyelitis.**—Allison says that in extreme forms of infantile paralysis, the wearing of apparatus and the use of crutches is necessary, that the upright position may be maintained. In extreme forms of infantile paralysis the wearing of heavy appliances may be materially lessened by the employment of operations designed to fix the joints. In cases in which there is good muscular power remaining in strong muscles, these muscles may be used to good advantage by transference of their tendons. Care should be taken that the insertion of these tendons is strong and permanent, and that the muscles pull to the best mechanical advantage. In certain cases tendon-transplantation may be supplemented to good advantage by arthrodesis. In slight forms of paralysis the grafting of nerves is a surgical procedure of recognized merit.

Journal of Nervous and Mental Disease, New York.

65 Ear Affections and Mental Disturbances. E. Amberg, Detroit, Mich.
66 Question of Protopathic and Epicritic Sensibility and the Distribution of the Trigeminus Nerve (Third Branch). C. L. Dana, New York.

64. **Psychical Importance of Ear Disease.**—Bryant reports several cases of auditory hallucinations which are interesting because of their evident dependence on catarrhal conditions of the ears, as shown by the cessation of the hallucinations when the aural conditions were corrected. The evidence points to some connection between ear disease and hallucinations of hearing other than mere coincidence. Bryant thinks it is probable that hallucinations of hearing originate in subjective ear sensations in most cases, and that cure of the coincident ear disease cures or assists the convalescence from the psychoses in a notable number of cases. Some cases of insanity appear to be excited by ear disease and the convalescence of insane patients is delayed by the presence of ear disease. Unilateral hallucinations of hearing, he says, are unquestionably due to unilateral ear disease.

69. **Diagnosis of Prostatic Hypertrophy.**—Jacobson has found two methods of value in making a diagnosis of hypertrophy of the prostate. These are (1) cystostomy, and (2) bimanual examination with a suitable sound in the bladder and the finger in the rectum. He has modified his cystoscope by dividing the circumference of the circular hard rubber at the ocular end of the instrument into eight parts by eight lines, and one vertical line placed on the handle or electrical connection of the instrument, so that each of the eight lines of the ocular end are separately brought into alignment with the line on the handle, thus dividing the circumference equally. In order to be able to measure the urethral length as well as to determine the size of an intravesical enlargement, the shaft of the cystoscope, near the ocular end, is ruled in centimeters. He prefers the perineal route for operating.

75 *A New Operation for Extreme Cases of Septal Deflection, with Presentation of a Successful Result in an Adult Case. J. Price-Brown, Toronto.
76 Causes and Treatment of Sterility in the Male. A. Fletcher, Toronto.

75. **New Operation for Septal Deflection.**—To remove the antero-posterior tension Brown makes a cross cut completely through both mucous membranes and cartilage and extending beyond the other two cuts, converting the two straight lines into the letter H. The points to which he draws attention in reference to it are these: First, that as the curvature of the cartilage from above downward gives it a greater width than it would occupy if it were upright in its normal position, the two longitudinal cuts should be so managed as to remove two long slips of the septal cartilage; and at the same time be made at an oblique angle, so that the cut edges can slide over each other. Second, that the cross cut of the H should be very decidedly oblique, cutting through both mucous membranes and cartilage with knife or chisel, so that in replacing the segments the posterior central segment of the septum will slide forward over its fellow and the anterior one backward. It

matters little how these cuts are made if the principle on which they are founded is carried out. The long strips of cartilage might be removed either by drill or swivel saw, or knife or ordinary saw of unusual thickness, or any improved instrument specially constructed for the purpose. The cross cut can be made by either chisel or knife. The immediate result of the combined cuts when made completely through both mucous membranes and cartilage is that all tension is removed, that two rectangular flaps are made by the H incision, the basic blood supply of each being retained, and that they can be pressed with ease into the normal position, their edges sliding over each other. The pieces will bend easily and, sliding over each other, are readily adjusted; they are retained in position by the use of the invaluable rubber splint, a single one on the convex side being the only one needed.

77 *Value of the Leucocyte Count in Cases of Appendicitis. R. P. Daniells, Toledo.
78 Present Position of Radiation in Treatment. G. Sichel.
79 Meeting of American Medical Association and Impressions of Historic Boston. C. P. King, Newark.

77. **Leucocyte Count in Appendicitis.**—Daniells made careful blood counts in 120 cases, all of which came to operation and were proved to be cases of uncomplicated appendicitis. He found that in the beginning of an acute attack of appendicitis there is, as a rule, a leucocytosis, but that in mild cases no leucocytosis may be present. A rapidly increasing leucocytosis in these acute cases means that the inflammation is increasing and extending, and this is true even when other symptoms show no change or perhaps a slight improvement. When cases do not come under observation until late in the attack and an abscess is already present, there is usually an increase in the white blood cells, but this is dependent on the amount of peristalsis which is allowed to take place.

82 Does the Bacterial Content of City Milk Influence the Infantile Death Rate? G. W. Goler, Rochester, N. Y.
83 Nervous Children. A. Church, Chicago.

80. **Weights of Viscera in Infancy and Childhood.**—A study of the average weights of the viscera in infants and children up to the age of five years showed Bovaird and Nicoll that there is a constant relation between the weights of the more important viscera, thus: The weight of the liver will average seven times that of the heart. The weight of the spleen will average one-tenth that of the liver. The weight of the kidney will average one-ninth that of the liver. The weight of the thymus gland as commonly given is excessive, owing to the acceptance of pathologic glands as the standard for normal conditions. The average weight of the thymus at autopsy is approximately 6 grams. There is no evidence of a growth of the thymus after birth under ordinary conditions, but under special conditions the gland does grow and even hypertrophy enormously.

98 Case of Malignant Endocarditis. G. S. Smith, Cleveland.

95. **Treatment of Typhoid.**—Phillips outlines the treatment that was employed in 1,070 cases of typhoid admitted to the Lakeside Hospital in Cleveland. The mortality in these cases was 7.9 per cent. The treatment does not differ from that usually employed. The patient is kept on a soft diet for four days, consisting of softened milk toast, eggs, junket, custard and well-cooked rice. The diet is then increased by the gradual addition of cereals, crackers, scraped beef, creamed chicken, bread and butter, and milk pudding. Milk is given between meals and in the evening. The convalescent diet is the same, with the addition of more meat, fish, potatoes, tea and coffee. The tub bath is used. Cholecystitis was present in 12 cases; intestinal hemorrhage occurred in 63 cases; perforation of the intestine in 29 cases; phlebitis in 42 cases; otitis media in 31 cases; cystitis in 9 cases and pyelitis in 2 cases.

97. **Convulsions in an Infant.**—Furrer reports the case of an infant four weeks old that had general convulsions, coming on about every five minutes day and night, since the fourth day after birth. No cause for the convulsions could be discovered. The infant was well developed, and in the best of health. Under treatment with castor oil and sodium bromid, one grain every three hours, and mercurial ointment, the baby recovered.

11 *Ovarian Pregnancy. J. T. Hewetson and J. Lloyd.

1.—See abstract in THE JOURNAL, Sept. 1, 1906, page 705.

11. **Ovarian Pregnancy.**—Hewetson and Lloyd report a case of ectopic gestation which they are satisfied arose within the substance of the ovary. The patient, aged 35, was referred for operation for a supposed subacute appendicitis. Since her last pregnancy menstruation had been quite irregular up to a few weeks of her present illness. She was taken suddenly with severe pain in the lower abdomen, which was followed by symptoms of collapse. Under treatment she improved somewhat and on the following day menstruation began (having been delayed for two weeks) the flow containing many shreds and little pieces. This continued for seven days, the pains recurring from time to time and being most severe in the right lower quadrant of the abdomen. The woman vomited after every meal. On opening the peritoneal cavity about two pints of porter-like fluid escaped, and still more was mopped from the pelvis. A mass of firm clot as large as a fist was removed from the deepest part of the pelvic cavity, being bound by firmer fibrinous clot, which formed the walls of an almost perfect cavity. The uterus was larger than normal, but was otherwise healthy. The right Fallopian tube was normal from end to end; fimbriæ were free and unattached. The right ovary was enlarged, and formed part of the walls of the sac in which the blood clot lay. A ragged opening in its posterior surface toward the pelvic cavity was evidently the source of the bleeding. The ovary and tube were, therefore, tied off with silk close to the uterus and removed. The left ovary and tube were normal. They were not removed. The pelvis was cleaned up with dry sponges and the wound was closed. The patient made an easy recovery. Chorionic villi were found embedded in the fibrin lining of the cavity. These findings, the authors believe, justify them in concluding that this was a case of promary implantation of a fertilized ovum within the substance of the ovary, and that by gradual distension and thinning of the part nearest to the surface rupture of the sac followed with expulsion of the mole into the pouch of Douglas. The adjoining ovarian stroma was intensely vascular, suggesting an intervillous circulation.

20½ First Report of the Expedition to the Amazon, 1905. H. W. Thomas.

13. **Epidemic Cerebrospinal Fever.**—In a lecture on this subject Stevens reviews the clinical history of the disease and emphasizes its specific origin, the diagnosis of lumbar puncture and the frequency of the disease in sporadic form.

14. **Submucous Resection Operation.**—Potter endorses the value of this operation and its superiority over other operations for deflections of the nasal septum.

17. **Twisted Pedicle.**—The three cases reported by Sutcliffe occurred in females, aged 15, 21 and 48 years, respectively. In the first case the diagnosis of appendicitis was made, but at the operation the disturbance was found to have been caused by a thin-walled cystic tumor which sprang from the left broad ligament. The second case also was one of left broad ligament cyst, the pedicle of which was twisted on itself three times. The third case was one of right broad ligament cyst with the pedicle twisted into a knotted ropelike cord. There was also a dermoid tumor of the right broad ligament.

20. **Case of Intussusception.**—In the case reported by Falconer the tumor was made to disappear by water inflation, but reappeared after each treatment. The intussusception was of the ileocecal variety. Falconer states that when an acute intussusception has existed for 30 hours the patient should be subjected to rational and scientific surgery without delay.

37. **Passage of Mineral Dust Through the Walls of the Digestive Tract.**—This communication from Calmette's Pasteur

stricting band has been applied in 86 cases of furuncles, carbuncles, abscesses, defective consolidation after fracture, and postoperative suppuration. The results are said to have been brilliant in every instance.

75. **Passive Congestion in Treatment of Tuberculous Fistulæ.**—Gaugele has combined passive congestion with suction therapy in treatment of tuberculous fistulæ, with excellent results. In one case a weakly lad with three long rebellious fistulæ was promptly cured by the application of suction vessels. When a fistula healed over he examined if there were a trace of secretion below the new skin. If so, he punctured the new skin and applied the suction vessel with very weak suction. In this way he was able to keep the fistula clean, and it then rapidly healed.

79. **Exposure of Heart After Injury.**—Wilms recently had occasion to operate in a case of bullet wound of the heart. Two hours after the injury he sutured the holes, taking three stitches in each. Considerably more than a liter of blood was found in the chest, but the patient recovered without reaction. Wilms gained access to the heart through an intercostal incision without attempting to cut an extensive flap. It allowed ample access to the front and rear of the heart while the whole operation was so rapid, simple and free from hemorrhage, that he advocates an incision in the fourth or fifth interspace as the standard procedure in such cases.

92 *Zur Aetiologie und Therapie der Eklampsie im Puerperium. W. Liepmann.

82. **Childbirth After Pubiotomy.**—The patient with extremely contracted pelvis on whom Reifferscheid first performed extramedian symphyseotomy or pubiotomy, was recently delivered of another living child without the necessity for further enlargement of the pelvis. A fibrous cicatrix had formed at the point of section, and this loosened during the pregnancy and stretched during delivery.

84. **Plastic Operation on Pelvis.**—Credé aims to enlarge the pelvis permanently, not merely during delivery. He has worked out a technic on the cadaver and has recently applied it with gratifying success in a clinical case. He advocates performing the operation at the beginning of pregnancy or even before conception, in case of a very contracted pelvis, or when much depends on bringing healthy children into the world, even if the pelvis is not very much deformed. His technic includes sawing the pubic bone at two points, the first section passing downward through the body and the second through the horizontal ramus. The part between is completely detached by a third, nearly horizontal, section slanting from the center of the first section to the obturator foramen. The part thus detached is transplanted forward between the halves of the severed body of the pubic bone, thus holding them permanently apart at a distance of 2 cm. The article is illustrated. In the case in which he operated to facilitate delivery the wound healed without reaction or temperature.

86. **To Detect Fetal Heart Sounds Early.**—Schwab advises pushing the contents of the uterus up, forcing them against the roof of the fundus. This he accomplishes by placin right hand at a right angle to the body, just above the physis, and pressing gently downward vertically and the ward toward the fundus. He then applies the stethosc the most bulging portion of the abdomen, a little abov umbilicus. The fetal heart sounds become distinctly a with this technic, even before the middle of the fourth m

87. **Roentgen Exposure of Ovaries During Pregnancy.**- researches on rabbits described demonstrate that Roe exposures of the ovaries induce degeneration of the ova arrest the growth of the fetus. The phenomena observed cate that the functional activity of the ovary, especiall internal secretion, is not without significance for the co ance of the pregnancy during its first half at least.

88. **Lumbar Puncture in Eclampsia.**—Thies states tl the 15 patients treated by lumbar puncture died, a m of over 42 per cent. The pressure of the cerebrospin was unusually high in all but one case. The prognosis to be better in the cases with lowest pressure. An effe the lumbar puncture was evident in only a few of th Profound coma was apparently relieved in some instanc

89. **Indications for Artificial Abortion.**—Ahlfeld urg eral practitioners to be careful about telling their that artificial interruption of the pregnancy is nec Careful study of the case and treatment in a hospital underlying trouble suggesting abortion may frequently r it unnecessary. In any event, he says, when referring patient to a specialist, write the particulars instead of t the patient what to ask for.

91. **To Enhance Resisting Powers of Peritoneum in C Operations.**—Hannes reports from Küstner's clinic that cases he injected 50 c.c. of a 2 per cent. solution of nucle in the form of sodium nucleiate, about 13 hours befo abdominal operation for carcinoma of the cervix. The re on the whole, were gratifying, and he is convinced that injections will prove a valuable aid in enhancing the resis of the peritoneum to infections. The reaction was al striking; the temperature rose one or two degrees C., w chill in three cases. Marked hyperleucocytosis was evide blood drawn from the lobe of the ear in nearly every He does not think that much can be anticipated from th jections when the resisting powers are at a low ebb. In of cachexia or existing infection it may prove possible to munize the patients by preliminary injection of killed tures of streptococci, according to Polano's technic. He is testing this, sometimes combining it with the nucleic injections.

92. **Treatment of Eclampsia.**—Liepmann ascribes eclam to retention in the liver of toxins generated in the plac The liver, for some reason, is unable to neutralize them. ing the lowering of the vitality by the birth process, unneutralized toxins pass into the circulation and, in ca a predisposition, affect the brain, kidneys or both, and in the syndrome of eclampsia. If the toxin injures princi the kidneys, then the symptoms will be scanty urine, albumin and casts. From 2,000 to 4,000 c.c. of physic salt solution should be injected, he states, with venesectio case of plethora, and three times a day a powder shoul given containing diuretin (theobromin sodium salicylat gm., and pulv. digitalis leaves and trit. camphor, each 0. If the toxin affects the heart, the pulse will be rapid an tering, and caffein and camphorated oil should be inject cutaneously. If the toxin affects the brain there will superficial respiration from paralysis of the respiratio edema of the lungs and convulsions. Treatment of of symptoms should include artificial respiration k days with half-hour intervals, and during the paus with cold water and cold packs. Narcotics should little as possible; the best, he states, is an enem chloral at a dose, with morphin only in case of agitation, 0.03 gm. at a dose. In his experience respiration and slapping with cold water have patients who were apparently moribund. The symptoms and treatment in two such cases are gi lated form
